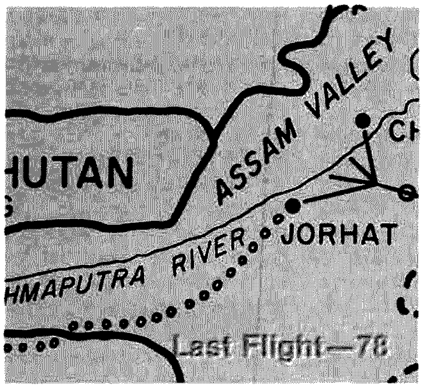
The Ups & Downs of VHF Contesting

73 MAGAZINE jan. 81



to doom any effort to failure. Bureaucrats exist by adhering to rules, and their greatest fear is making a decision or proposing some idea which is controversial and could thus reflect poorly on their record.

In this I found that the problems of dealing with China are quite different from dealing with most other countries for, despite the impressions we have been getting from our media, no one person is in charge in China. There are many factions, all jostling for more power, and the country is thus run by committee. This probably goes a long way towards explaining why they seem to be about a hundred years behind us.

Despite all these problems, I am going to start work on the situation and see what I can do to get some interest in the highest official circles. I'm available to fly over there and deal directly, should that be beneficial. Sure, I'd love to have a week or two of DXing from China, but I have too much going on these days for that, so perhaps we can work on longer range plans for getting amateur radio introduced. I know that a number of DXers will be glad to help out, should anything start to break loose. Lloyd Colvin (W6KG) and his wife Iris (W6QL) would be on a plane tomorrow if they thought it would help.

The trip to Asia was, again, fantastic and I'm sorry that more of you did not have the time to go along. Those who did had the time of their lives. I did write about it and invite all of you to make the trip. . . and it was certainly a bargain, with first class hotels everywhere, wonderful meals, and the excitement of a completely different world.

BOMBSHELL IN TAIWAN

In addition to my talk to the China Youth Association scheduled in the Grand Hotel, I was also called upon to speak briefly to several hundred members of the electronics industry on Taiwan at a business breakfast. I made all the papers with my short talk.

Without putting you through the complete text of the talk, I got their attention by saying flatly that Taiwan's electronics products, while impressive, were not by any means state of the art. I pointed out that Taiwan was in the position of having to import technology from Japan and the US and was depending entirely on being able to pro-

FIGHT BACK

Have you ever heard of David Horowitz? No, David is not an amateur radio operator. David Horowitz is the host of a weekly syndicated NBC television program called *Fight Back*. David is the author of a new book of the same name, and, in my opinion, it's the best book on consumer awareness I have ever set my eyes on. Basically, it tells you how to avoid getting ripped off and what to do if you are. I won't try to review the book here, but it's more than just another consumer awareness volume. I *will* tell you the same thing I told David a few weeks ago when I happened to run into him at the NBC studios in Burbank: "That's one heck of a book!" If you ever have been ripped off or if you want to be sure it never happens to you, then read *Fight Back*.

CALIFORNIA VS. THE PAY-TV PIRATES

On October 1st, 1980, California Governor Jerry Brown signed a law into the state statute books which this author feels is one of the most irresponsible pieces of state legislation ever enacted. In fact, by the time you read this, the law may be a thing of the past, this because many people have vowed to fight it on various grounds. The law I speak of is called Section 593e of the California State Penal Code. It makes it a crime for any person "who for profit manufactures, distributes, or sells any device, plan, or part for the knowing purpose of facilitating an unauthorized interception or decoding of subscription television signals." Additionally, it provides for a jail term of up to 90 days and/or a fine of up to $2500 per count on any conviction. Not a bad law, you say? I quite agree. But not a law for California or any other state to enact.

Here, again, we see the classic example of a state trying to usurp the jurisdiction of the federal government. Unless the Communications Act has been rewritten without anyone noticing, the role of the FCC in such matters has been clearly defined for years. It is not the prerogative of California or any other state to try to usurp that which is governed by federal jurisdiction. But neither our Governor nor State Assemblyman Mel Levine, who sponsored the bill, seems to have bothered to read the Communications Act or any subsequent FCC interpretation. They never bothered to consult the findings in the Cerritos tower case in which the government stated specifically that it had jurisdiction over radio communication, and, in effect, told California to keep its nose out of the FCC's business. No, our state legislators failed to do their homework. If they had, they would not have permitted themselves to get caught in what may well become a "Catch 22" situation.

No, I am not on the side of the pay-TV pirates. I want this clear from the start. I understand the intricacies of pay-TV, the most important of which being that for subscription television programming to survive, the companies that provide such services must be assured that they will make a profit. If this assurance is destroyed because of widespread piracy of such services, then subscription television will fail, and eventually there will be nothing left to pirate. However, I do not think that the solutions now being addressed are the proper ones. Laws are only as good as the enforcement that goes with them. In the case of the California ordinance, most lawyers with whom I have consulted agree that the federal government, not the state, is the governing body, and that 593e was nothing but a lot of wasted effort.

Further, I have to question the concept of getting federal laws passed to protect subscription television. While the Commission may be good at generating rules and regulations to govern just about every eventuality occurring in the electromagnetic spectrum, their record on enforcement leaves a bit to be desired. And...what's to keep someone or some group from challenging such laws, the result of which is a court battle that will last years and cost us taxpayers. No, my feeling is that there is only one answer to the problem of pay-TV piracy, and that answer is technology.

The major problem, as I see it, comes from the fact that the majority of subscription television systems are just too easy to pirate. As with anything else, when the systems were developed, the cost factor of the system was one of the prime concerns to those developing it. Therefore, with but one exception, the pay-TV encoding systems of today are so simple to decode that a high-school student with only a bit of knowledge in electronics can overcome them. In fact, if you know how to read and understand a composite TV video waveform, there is no way for you not to figure out how a given subscription television system works. Once you have this knowledge, you are halfway home.

The key to combatting subscription TV piracy then becomes one of developing a pay-TV encoding system so complex as to make piracy uneconomical. In the end, it comes down to simple economics. If it's cheaper to purchase a pirate decoder than to pay the monthly subscription fee, then such decoders will become as fashionable as linear amplifiers for CB. But, should the subscription television services finally get together and, with their collective resources, develop a highly complex encoding/decoding system, one so complex as to make illegal decoders non-cost-effective items, they can ensure the longevity of subscription television in this nation.

Frankly, I suspect that the opposite will happen. I feel that most subscription-TV services are themselves such bureaucracies that they cannot see the forest for the trees. They will probably continue their court battles. They may eventually obtain the federal laws they seek to theoretically curtail the manufacture and distribution of such devices. In the long run, they will be the losers. I need only point to the 10-meter amplifier ban to make my point. The only one who tells us that the amplifier ban is a success is the FCC. You wouldn't know it by listening to 11 meters and hearing operators extol the virtues of their *new* "Super Whizbanger 10K" and such. If the subscription-TV people want a quick solution, leave it to the engineers to find it. Keep trying to change the laws, and they will only develop the same black market for decoders that now exists for CB linears.

I doubt if it will ever be possible to curtail the piracy problem completely. There will always be an individual somewhere who will figure out even the most complex of systems and find a way to beat it. Sort of like those who sit for hours trying to break the "top-secret" control codes on remote-base and repeater systems. But, they are a minority and as long as they cannot produce a cost-effective product to mass merchandise, they are no real threat to the survival of pay-TV. A few years ago, I predicted to a friend that this problem would occur. I based my assumption upon my understanding of the current pay-TV systems and human nature. Now, three years later, I find that I am correct.

Here, in California, and elsewhere, the problem with subscription TV piracy is growing, and, as I predicted then, the pay-TV people are grasping for straws in trying to solve it. Yet, the answer is in front of them. It will cut deeply into corporate earnings in the short term, but will give them long-term security. Let's see if these bigwigs of high finance are smart enough to realize this and initiate a technological change. If they're the typical bureaucrats I think them to be, I doubt if they will. In the end, you and I will pay the price, as cases are fought with our tax dollars. Even those of you who do not have subscription television will be the losers if this happens. Maybe we can at least start the ball rolling to forbid the use of our tax dollars for use in such litigation. Frankly, if the pay-TV people want protection, then they should be prepared to foot every penny it costs. If this means that it will cost their subscribers more, then so be it.

By the way, I am one of this nation's pay-TV subscribers and want to see subscription TV survive. I enjoy our HBO service and feel that it's worth the monthly service fee. If I wanted to pirate

CONTESTS

Robert Baker WB2GFE
15 Windsor Dr.
Atco NJ 08004

HUNTING LIONS IN THE AIR CONTEST

Starts: 1200 GMT January 10
Ends: 1200 GMT January 11

The contest is sponsored by Lions Clubs International and coordinated by Lions Club Rio de Janeiro Arpoador, Brazil. Participation in the contest is open to all duly licensed radio operators, Lion and non-Lion. There are two modes—phone and CW. Participation in both modes is allowed, but points are counted separately. All amateur stations participating must operate within their licensing regulation. Separate categories will exist for single operator and radio clubs/societies. Multi-operators may participate, but each prefix must be listed on the log.

Use all bands, 80 through 10 meters. Only one QSO with the same station on each band may be counted. Remember that phone and CW are counted separately!

EXCHANGE:

RS(T) and sequential QSO number. When contacts are made with Lions and Leos, the name of the Lions Club or Leo Club contacted should be clearly identified.

SCORING:

QSOs within the same continent count 1 point, while those between different continents count 3 points. Score 1 extra bonus point for each QSO with a member of a Lions Club or Leo Club and 5 points for a QSO with a member of the Lions Club Rio de Janeiro Arpoador. Contacts between Brazilian stations and members of the Arpoador club will count only 2 extra points.

AWARDS:

Lions Club International will present awards for single operators for first, second, and third place on both modes. The first-place winner in each mode will receive a trophy, the second-place winner will receive a medallion, and the third-place winner will receive a plaque. A trophy will be awarded to the first-place radio club on each mode. Certificates will be awarded fourth- through tenth-place winners in each mode for single operators. In addition, each log sent by participants, radio clubs, or radio societies will receive a special certificate. The contest committee will also select and award the most active Lions Club participating in the contest.

ENTRIES:

Keep a separate log for each mode. Each participant will note in the logs the callsign and information exchanged. Confirmation of contacts will be made by comparing the logs of the participants. Participants should send their logs not later than 30 days after the contest to: Contest Committee—Hunting Lions in the Air, Lions Club of Rio de Janeiro Arpoador, Rua Souza Lima #310, Apt. 802, 22081 Rio de Janeiro RJ Brazil.

2nd ANNUAL INTERNATIONAL 160-METER PHONE CONTEST

Sponsored by 73 Magazine
Starts: 0000 GMT January 17
Ends: 2400 GMT January 18

This is the second annual 160-meter contest sponsored by our magazine. The object is to work as many stations as possi-

AMATEUR RADIO NEWS SERVICE (ARNS)
1980 PUBLICATION CONTEST INFORMATION

Mail one copy each of any of three issuances during the period from July, 1979, through July, 1980, to:

Arny Gamson K6PXA, Chairman
ARNS Publication Contest
8034 Gentry Ave.
North Hollywood CA 91605

Papers will be reviewed by a team of three judges. Points will be awarded by each judge independently based upon the criteria discussed below. Final average totals will be adjusted up or down based upon a group reevaluation of all papers. All papers will receive an award and, based upon adjusted point value, will be judged OUTSTANDING, EXCELLENT or HONORABLE MENTION. All papers will also receive a summary critique on their favorable qualities and the judges' constructive suggestions for improvement.

Criteria for judging will include achieving the apparent goals of:

- Purpose of publication
- Interest to readers
- Imagination and attractiveness of layout
- Mast, titles, and layout
- Humor and cartoons
- Members' involvement and contribution
- Ease of readability of product

The following "housekeeping" items will be considered:

- Date and frequency of issue
- Name and address of editor and officers of sponsoring organization
- Utilization of ARNS emblem and ARNS contributions from the *Bulletin* (if member)
- Minimal effect will result from method of reproduction unless it affects the readability
- Technical articles and recruiting/training/subscriber solicitation material will be evaluated on an appropriate basis

Decision of the judges will be final. Scores/critiques of individual papers will be issued to individual entrants. Categories earned will be publicized.

There is no entry fee or membership in ARNS required. The contest is international and open to all amateur radio clubs, societies, organizations, groups, etc., issuing periodicals. Include separate recruiting, training, etc., material issued in connection with your paper.

Deadline for submissions two weeks after receipt of this publication.

INFORMATION TO BE INCLUDED WITH PUBLICATION CONTEST APPLICATION

1. Name of publication
2. Frequency of issue
3. First issue date
4. Circulation (No. sent to members/Complimentaries)
5. Club dues or subscription rate
6. Sponsoring group (if any)
7. Club mailing address
8. Editor's name, call, phone number
9. Editor's address
10. Editor's city, state, ZIP
11. Editor: How long this paper? Other papers (list and how long associated)?
12. Method of printing (offset, copier, stencil, spirit)
13. Approximate cost of printing each issue
14. Postage
15. Principal objectives of your paper
16. Items judged which you feel are *not* applicable to your paper
17. Remarks
18. Amateur Radio News Service member?

'AWARDS

Oak Harbor WA 98277

COMPU-WARD

As publicized in over 25 individual amateur radio publications throughout the world, the COMPU-WARDs, sponsored by Micro-80 Incorporated, are available to licensed amateurs and shortwave listeners worldwide. Emphasis of these award programs is focused on the advancement of both the amateur radio and computer hobbies through demonstrated excellence in the art of computerized communications.

Stations applying for these awards may or may not have a computerized station of his/her own; however, *all stations contacted must be computerized*, meaning the contacted station must have his/her transmitter interfaced with a computer, such as the well-known TRS-80, Apple II, Commodore PET, Heathkit, Atari, etc.

To be valid, all contacts must be made on or after January 1, 1980. There are two (2) awards being offered: (1) HF bands—29.7 MHz and below; (2) VHF/UHF—50.0 MHz and above.

All contacts must be made on one or any combination of the following modes (including any modes authorized by the FCC since the release of this announcement)—RTTY, SSTV, CW, and ASCII. Crossmode communications will not be recognized for these awards.

Single-band and mixed-band endorsements will be given with each band segment (HF, VHF, UHF, etc.). Crossband operation will only be accepted for OSCAR contacts. All OSCAR contacts will be considered only for VHF/UHF accomplishments even though some of the OSCAR satellites have receive frequencies on 10 meters. Contacts via repeaters are acceptable.

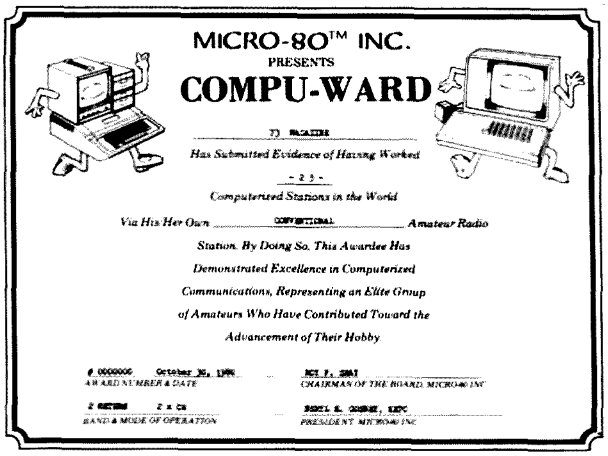
To qualify for either COMPU-WARD:

Applicants *with* a computerized station of his/her own must contact a *minimum of 15* other computerized stations on the bands and modes authorized.

Applicants *without* a computerized station of his/her own must contact a *minimum of 25* computerized stations on the bands and modes authorized.

To apply, prepare a list of contacts for each award. In prefix order, list each call worked, mode utilized, frequency or band of operation, and date and time of each contact made. *Do not send QSL cards!* Have your list of contacts and supporting QSL cards verified by two fellow amateurs or a local radio club official. The services of a notary may be sought if applicants prefer.

Forward the verified list with $4.00 for each award. Send your application to the Oak Harbor address of Micro-80 listed above. Foreign stations may substitute the awards fee by enclosing 10 IRCs for each award sought.



Last month we reviewed the very challenging Gozo Island Award and completely overlooked the very beautiful DIP-MED Award Diploma. My apologies to MARL for this obvious error.

DIP-MED AWARD

Awarded to any licensed amateur, the DIP-MED Award has no band or mode restrictions; however, single band or mode accomplishments will be recognized if requested at the time application is made.

To qualify, HF applicants must work a minimum of 15 Mediterranean countries including 9H Island of Malta. On VHF, only 5 Mediterranean countries including 9H Malta need to be confirmed.

To apply, prepare a list of claimed contacts indicating callsign, date and time in GMT, the band and mode of operation, and the country contacted. Have this list verified by at least two fellow amateurs or a local radio club official. Forward the application and $3.00 or 12 IRCs to: MARL, PO Box 575, Valletta, Island of Malta.

Mediterranean countries include: Malta, Spain, Balearic Islands, Ceuta and Melilla, France, Corsica, Morocco, Algeria, Tunisia, Monaco, Italy, Sicily, Sardinia, Greece, Cyprus, Crete, Dodecanese Isles, Gibraltar, Yugoslavia, Albania, Israel, Lebanon, Egypt, Turkey, Syria, and Libya.

GUAM ISLAND AWARD

I am proud to announce the very latest award being offered by the Mariana Amateur Radio Club of Guam Island, known as the Guam Island Award. The requirements of the award are very straightforward. Applicants must work and confirm at least five (5) individual amateurs located on Guam Island.

There are no band or mode restrictions; applicants must have their list of contacts verified by at least two amateurs or a radio club secretary. Be sure to give the usual log book information plus the name of the operator for the contact to count.

Enclose your application and an award fee of $1.00 or 5 IRCs to: Mariana ARC of Guam, PO Box 445, Agana, Guam 96910.

ANNUAL 73 MAGAZINE AWARD ENDORSEMENTS

The end of 1980 brings to a close another eventful year of enjoyable operating. Award seekers can now tabulate their totals and make application for their annual endorsements for the *73* DX Country Club Award and the Worked All USA Award. To learn more about both of these very challenging awards and the seventeen other programs which accompany them, turn in your back issues of *73* to my Awards column for the months of September and October. The entire details of the *73 Magazine* Awards portfolio are featured there.

WABP AWARD OF BELGIUM

The UBA Awards Manager, ON5TO, has announced the very popular WABP Award Program. This award is available to licensed amateurs and SWL stations. There is no limit as to date; there are no band or mode restrictions.

To qualify for the WABP Award, the applicant must work and confirm contact with each of the nine Belgium provinces on a minimum of two amateur bands.

Once the requirements have been met, have your list of contacts verified by a radio club official. Do not send QSL cards!

Enclose your verified application and five (5) IRCs to: ON5TO, UBA Awards Program, PO Box 634, Brussels, Belgium.

Belgium provinces include: WV—West Flanders; OV—East Flanders; AN—Antwerp; LM—Limburg; LG—Liege; LX— Luxembourg; NR—Namur; HT—Hainaut; BT—Brabant.

While in Belgium, we have learned of another award incentive which should capture the interest of most DX stations, the Onion Award.

THE ONION AWARD OF BELGIUM

Licensed amateurs or SWL stations will find this award a considerable challenge. Only contacts made with the Aalst section of Belgium will count and these contacts must be established after January 1, 1975, to be valid.

RTTY LOOP

Marc I. Leavey, M.D. WA3AJR
4006 Winlee Road
Randallstown MD 21133

Let's start off the New Year with a look back at some things we have mentioned in the past few months.

Several months ago, I reviewed the Jameco JE-610 ASCII keyboard. One of the troubles I noted was that, in spite of advertisements proclaiming the "full 128-character ASCII character set," the keyboard is unable to generate one code, $1F, as supplied, and another, underline ($5F), is omitted from the keyboard, although it can be generated with some manipulation. I related that Jameco acknowledged the problem, although no apparent fix has been offered. Well, take a look at the latest ads for the keyboard. No longer is the "full 128-character set" claimed; now the keyboard's "60 keys generate the *126* characters, upper- and lowercase ASCII set." Don't change the hardware, just the software, or something like that! Oh, well.

Also back a few months, we reviewed the iRL FSK-1000 RTTY demodulator. In it, I issued a challenge, albeit half-heartedly, to tell which button on the panel was pushed. Well, in response to the many questions, only the "170-Hz Shift" button is depressed. All others are in the "out" position. Study the picture if you don't believe me.

Now, quite some time back, extending over the many subsequent months, we have been following the progress of a firm known as Teleprinter Art, Ltd. To my knowledge, no repeat inquiries to the firm have been answered and, as of this writing date, I am forwarding a good deal of the correspondence and details received to the Postal Inspectors. I will try to keep anyone forwarding information to me informed of the progress of any investigation.

About a year ago, we passed along the saga of George Firmin WA4FSK, who wondered what weather transmissions such as 66228 05210 05315 05323 04928 66028 06525 06234 05838 mean. Now along comes a note from Robert Munro in Newport, R.I., who used a book entitled *Worldwide Marine Weather Broadcasts* to decode the above. His translation reads: 66228 = Warm front at surface, weak, and frontal characteristics decreasing. 052 N. latitude, 10 W. longitude, 053 N. longitude, 15 W. latitude, etc. 66028 = Quasi-stationary front at surface, weak, little or no change. Frontal characteristics diffused. 065 N. latitude, 25 W. longitude, etc.

Thanks to Robert for the help. He wonders if anyone has a computer program to decode this type of information. I would suggest that the data is encrypted in a rather straightforward manner and that anyone reasonably fluent in BASIC should be able to put the book's tables into a program. Ask around your area.

While we're talking about computers (slid into that one, didn't I?), George Gadbois W3FEY passes along his contribution in the form of a UART interface for the RCA VIP computer. This allows George to use his VIP, which is an 1802-based computer, on Baudot and ASCII. His straightforward design is shown in Fig. 1.

George also noted that the Red Rose Repeater Association in Lancaster, Penn., is in the center of a few two-meter RTTY repeaters. The Harrisburg machine is on 147.975/.375 and a "computer link" to Eagleville may be found on 146.235/.835. Keep up the good work, fellas!

Buzz Gorsky K8BG, of Carlisle, Penn., writes in regarding his Model 15. It seems as though a non-overline, automatic CR/LF gizmo has been added, and Buzz wants to turn it off! Of course, with such a device, intentional overlines, such as in many pictures, are impossible. Well, Buzz, there are at least three non-overline schemes I have seen used in a Model 15, and how you defeat it depends on which one or another you have. The best I can offer, sight unseen, is to look for a lever or hook that the typing basket trips as it passes the sixty-fifth space or so, roughly where the bell would ring. This usually is the actuator and has a lever which can be swung out of the way. Perhaps some of the RTTY nuts in the Red Rose Repeater Association can help you. Write them at PO Box 5029, Lancaster PA 17601.

73 does get around. A letter from John L. Webster 9Y4JW/8P6KX in Trinidad, asks about the software to put the 6800 computer on RTTY. Well, John, over the past few years several separate receiving and transmitting routines have been published in this column. Copies of these are still available at $1.00 each to cover reproduction and postage. However, these two have formed the nucleus for a bigger and far better program, a full transceive program for RTTY with a 6800. Featuring preloadable buffers, variable speeds, and a true FIFO, the program fits in less than 4K of memory. Want more? How about one key RYRY, QUICK BROWN FOX, and ID, and throw in a CW ID to boot. And how much will this wonderful program cost? Why, not a cent more than you already spend, for it shall be published soon right here in *73*! So don't let your subscription lapse; watch for this fantastic program.

Kevin McKewen WA3LPK, a new RTTYer here in the Baltimore area, has acquired a HAL ST-5 and AK-1 setup, sans literature. He wonders if data is still available. Sure is, Kevin. HAL maintains a full spectrum of literature on all their products, and I am sure that they would be glad to help out anyone who drops them a line at HAL Communications Corp., PO Box 365, Urbana, Illinois 61801. And don't forget to mention RTTY Loop, OK?

Anyone around Rockland, Massachusetts, want to give a newcomer a hand? George Beaupre KA1CGP is putting a Model 32 on the air and is looking for suitable demodulators. This brother of the ASCII Model

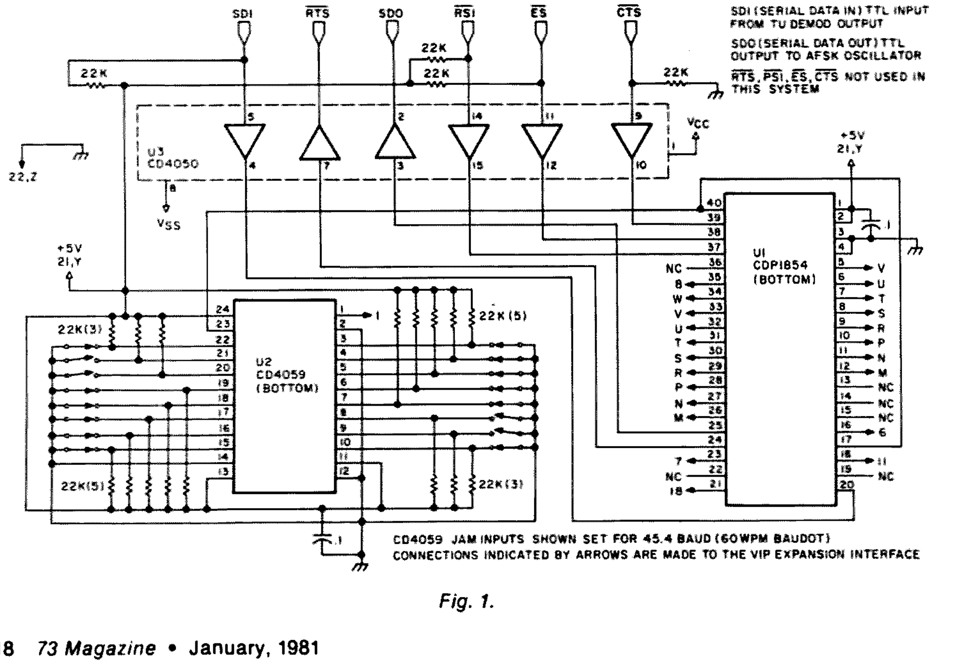

Fig. 1.

LETTERS

H 5 H, COMRADE

This letter has been started at least a half-dozen times during the past several months, only to be pushed aside by the press of some other matter and to then be restarted when triggered by something I read or heard.

This time, the "kick" was a comment of yours in *73* calling attention to the fact that the activities of the Russian Woodpecker were markedly reduced during the time WARC was in session. I suspect, for reasons that I'll try to make clear in this letter, that although your observation is quite correct, factors other than WARC may have played a significant role.

Some months back, I found it necessary to visit the Bonn-Cologne area of the Federal Republic of Germany, a locale in which there are a great number of good friends. Some are still quite active, professionally speaking; others are retired or (as am I) semi-retired.

I decided to make an unannounced call upon one of my better friends in Bad Godesberg, Herr S., who had retired from a very senior position in the Federal Ministry of Defense a few years back.

Frau S. met me at the door as casually and as graciously as though I'd never been away and then knocked the pins out from beneath me by stating quietly that my good friend Gunter had passed away only weeks earlier. She invited me in, but I'd had enough for one day.

I went over to the Weinhaus Maternas. Frankly, I've never thought too much of the place. My wife and I used to dine there from time to time until John Le Carre mentioned it in his book, *The Spy Who Came*... After that, the prices and the crowd increased while the...well, enough said!

One thing, though—if anyone were to be found anywhere in town, it would be there. Or back at the American Embassy club in Plittersdorf, and I didn't feel like driving over to the American community right then.

I was shown to an empty table and, before my eyes were fully adjusted to the light level, someone sat at the table across from me. Actually, I didn't really have to see him—the voice and accent were enough. It was Alex K. He'd been the scientific and technical attache at one of the eastern bloc embassies during most of my period there. I thought that he'd left about the same time as I. We'd met frequently at formal functions but I don't recall ever before having been with him in as private a situation as right then.

I might add that I had often teased him about defecting to our side. He has and had a great sense of humor and took the kidding in stride...I think. At any rate, he seemed to sense my mood and appeared to be really trying to cheer me up.

After a few glasses and some trivial banter about mutual acquaintances, my humor gradually restored itself, but it was clear that Alex didn't realize it. It was about then that he inquired if there was anything that he could do for me, meaning, of course, to further cheer me up. I chose deliberately to misunderstand that. And now we come to the point: I asked him why his friends didn't turn off that "damned over-the-horizon radar" and stop "screwing up" the ham bands.

The man was shocked! He looked at me in total disbelief, accusing me of once again pulling his leg. He refused to accept the statement that the Woodpecker (by the way, he found the name amusing) was really bothering US hams. He mentioned that there were many amateurs in countries much closer to the radar's transmitter site than are the Americans.

Then, as I recall it, he said something about their technology being better than ours and able to cope with simple periodic interference. Finally, he noted that the West German amateurs seemed to have reduced the problem, referring to a technical paper that he'd seen in *CQ DL*, the FRG ham magazine, sometime in the summer of 1978. (Editor's Note: Also see *Ham Radio*, June, 1980.)

Still feigning a by-then completely dispelled ill humor, I said something like, "Dammit, I'm not smart enough, personally, to engineer a blanking circuit to eliminate the pulse noise for each of my rigs! Why don't you do the whole world a favor and just turn the thing off?"

Imagine my surprise when, after a rather lengthy pause, he very quietly said that he supposed something could be done to alleviate the problem. He didn't elaborate on that statement but did go on with something in the same vein. He said that if "that" (sic) doesn't take care of things, whenever the signal is exactly on my frequency, I am to swing my antenna to beam a signal over the pole and to send "H 5 H" in Morse.

I distinctly recall his telling me that the dot frequency should be exactly 10 Hz (about 13 wpm), as it was obvious that he was suggesting synchronization with an unnamed something, such as, for example, the Woodpecker's pulse repetition frequency. He said no more on the matter, turning the conversation towards questions of my family's health and other innocuous subjects. I left Alex and Maternas' shortly thereafter.

The meeting was prior to WARC so one can't say whether it was WARC or that chance encounter that resulted in a lessening of the Woodpecker's activities. It does seem to me that the interference has been somewhat less than in the past, even since the WARC.

I, of course, will neither admit to ever sending a coded "H 5 H" in order to clear a frequency nor will I suggest that others try Alex's proposed solution because I'm not sure whether the FCC would call such a transmission illegal coding or deliberate interference. I thought, however, that it might interest everyone to know the possibilities, not to mention knowing *really* why the Woodpecker is down.

(Name withheld by request)

Many of us have found that synchronized dots sent on the Woodpecker frequency will move it. Somehow I doubt if the FCC would have any objections to such counteraction to this invader of our bands.—Wayne.

20-YEAR KUDOS

Congratulations on 20 years of *73*! And what a fabulous issue to commemorate!

You know, I have every issue of *73* here on two shelves, and I consider them to be one of my most valuable possessions.

Best luck in the next 20 years!

Ron Johnson WA5RON
Austin TX

THINK POSITIVE

Happy Anniversary! Keep it up!

E. P. Rolek K9SQG
Dayton OH

A GOOD INVESTMENT

About 20 years ago, I took a chance on a new ham magazine called *73*. I invested my life's savings (students were very poor in those days and so were magazine publishers) in one of your life subscriptions. The deal was your life or mine.

I figure that both of us have a good investment in each other. From those early days, the magazine and you have grown and become prosperous; so have I. I now am one of those "electron" engineers. Ham radio had something to do with it. I hope the next 20 years are as good for both of us.

Until I read the anniversary issue editorials, I did not know that you were a member of MENSA. So am I.

Clive Frazier K9FWF/4
Orlando FL

CONSERVING ENERGY

Don't you think it would be appropriate at this time to devote one page of *73* to ideas and concepts of conserving energy? I'm sure amateurs the world over have experimented and come up with systems. I utilize a large heat sink placed on a coal stove and blow air over it with a muffin fan. I get heated air at 90°. I am now working on a pre-heater for the fan air by building a jacket around the stove pipe and pulling the air through it.

FUN!

John Edwards WB2IBE
78-56 86th Street
Glendale NY 11385

This month's "Fun!" offering should really set your heads spinning. Instead of concentrating on one specific operating endeavor, as in our previous quizzes, this month we'll be testing you on the entire gamut of amateur radio history, everything from spark to space communications, with lots of other interesting highlights in between. So get those thinking caps on, for this month we learn about ham history.

ELEMENT 1—CROSSWORD PUZZLE (Illustration 1)

Across

1 One end of first transatlantic QSO
2 End of contact
8 Morse question mark
9 British tube
11 Disaster Radio Service (abbr.)
13 "Shahland" prefix
15 Upstart ham organization of 1950s (abbr.)
17 Status of 11-meter amateur band
19 Initials of government man who reopened our bands after WWI
20 Low frequency (abbr.)
23 Former deceptive ham outlet
26 WWII ham substitute (abbr.)
28 Irish prefix
29 It replaced spark (abbr.)
32 80-10 meters (abbr.)
34 Old receiver
36 Our fate
38 Caribbean QTH (abbr.)
39 Former ham manufacturer

Down

1 6-meter predecessor (2 words)
2 Old traffic post (abbr.)
3 What we get on
4 Before SOS
5 Greek prefix
6 New Novice-type call
7 Triode inventor
10 Idle ham
12 November contest (abbr.)
14 Wouff__________
16 Audio frequency (abbr.)
18 Element (abbr.)
21 FCC predecessor (abbr.)
22 Long wave (abbr.)
24 Old FCC agent (abbr.)
25 Equipment
27 ARRL appointee (abbr.)
30 QRZ?
31 FCC legal step (abbr.)
33 RACES official (abbr.)
35 Cycles______second
36 Bad op
37 "The Old Man" (abbr.)
38 Former Novice prefix

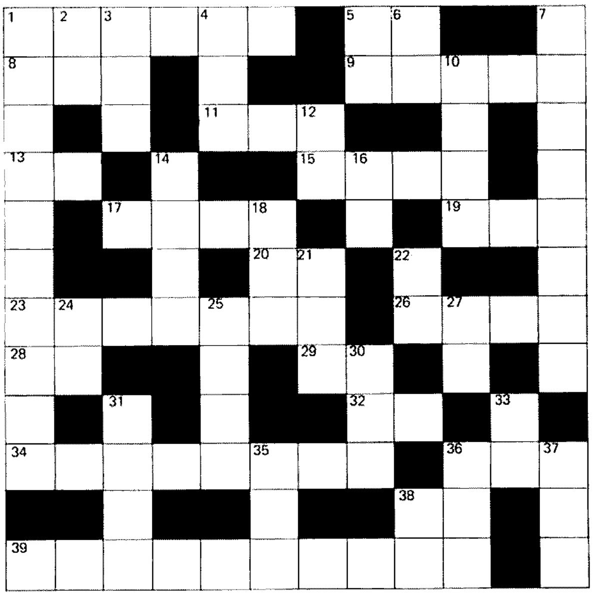

Illustration 1.

ELEMENT 2—MATCHING

Match the former ham manufacturers and distributors in Column A with their QTHs in Column B.

	Column A		Column B
1	E. F. Johnson	A	Brooklyn NY
2	RCA Electron Tubes	B	Roslyn NY
3	Gonset	C	Chicago IL
4	Lafayette Radio	D	Millington-Watchung NJ
5	Atlas Radio	E	Indianapolis IN
6	Hammarlund	F	Hicksville NY
7	Hallicrafters	G	Council Bluffs IA
8	Regency	H	New York NY, Mars Hill NC
9	Uncle Dave's Radio Shack (Fort Orange Radio)	I	Oklahoma City OK
		J	Waseca MN
10	Amperex	K	Rockford IL
11	Greenlee Tool	L	New York NY
12	Sonar Radio	M	Boston MA
13	Galaxy	N	Albany NY
14	Terminal Radio	O	Kansas City MO
15	LTV-University	P	Harrison NJ
16	RME-ElectroVoice	Q	San Francisco CA
17	Burstein-Applebee	R	Buchanan MI
18	Alltronics-Howard	S	Jamaica-Syosset NY
19	Squires-Sanders	T	Burbank-Anaheim CA
20	Sideband Engineers	U	Oceanside CA

ELEMENT 3—MULTIPLE CHOICE

1) In 1921, the "Transatlantic Tests" were held to see which amateur could first transmit a signal from America to Europe. What was so unusual about the first ham to accomplish this feat?

1) He was a pirate signing 1AAW.
2) He sent his signal on 2 meters.
3) His signal was frequency modulated.
4) He was not an American, but a Canadian.

2) Back in the 1950s, General Electric sponsored an annual award presented to an "amateur who has rendered outstanding public service." The name of this award was:

1) The Maxim Award.
2) The Baldwin Cup.
3) The Edison Award.
4) The WB2LWJ Certificate of Merit.

3) Speaking of awards, the Elser-Mathes Trophy, currently on display in Newington, will be awarded to the first amateur who accomplishes:

1) A 2-way contact with Mars.
2) WAS on a microwave band.
3) The first digital phone transmission.
4) DXCC on fast-scan television.

4) We all know that Guglielmo Marconi invented radio. But did you know that he had a brother who helped him with many of the invention's trial experiments? What was the first name of this "other" Marconi?

1) Luigi
2) Alfonso
3) Kevin
4) Luciano

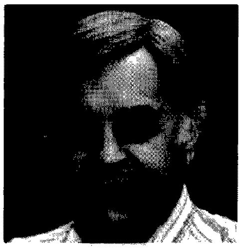
LEAKY LINES



Dave Mann K2AGZ
3 Daniel Lane
Kinnelon NJ 07405

I've had a hankering for a long time to write about flea markets. And now that the season is over for this year, here in the north, anyway, I thought that I might make some observations. Like most guys who are somewhat quick on the trigger (I'm sometimes known as the quickest mike button in the east), I was going to shoot from the hip, quite convinced that I had a valid point of view. But after some discussions with several friends, I made a 180° turn. I must confess that I had not delved very deeply below the surface, and my ideas had been all wet.

The most important thing about flea markets is that if they weren't included, none of our ham conclaves could begin to draw the huge attendance they do. In fact, many convention symposiums and caucuses are relatively poorly attended, but flea markets are generally so crowded that you invariably have to elbow your way to get through the aisles. Flea markets are unquestionably the most popular attractions of all. Why should this be so?

Because the idea of something for nothing (or relatively nothing) is one of the most powerful motivations in all Creation. That's why there was a huge crowd when they first opened the Oklahoma Territory, why hordes of people flocked to Sutter's Mill and the Klondike when someone struck gold, and why department stores are thronged on Washington's Birthday. The prospect of a big bargain is almost irresistible.

Some flea markets are good, and some are not so good. It all depends upon just how well the individual makes out in his or her buying and selling. If you are on the prowl for a certain item and you happen to find it at a good price, then you are apt to conclude that it's a good flea market. But if you load a couple of tons of stuff into your pickup truck and lug it three or four hundred miles, then don't succeed in selling any of it, you might well be justified in thinking it's a lousy one. It all depends on your individual frame of reference... like anything else.

Flea markets generally depend upon word of mouth for success. If a given flea market turns out to be fruitful for a large number of people, you can bet that it will be even better attended next year. For there are enormous multitudes who look forward to these things, and they think nothing of traveling hundreds, if not thousands, of miles to attend. They go with bulging pockets, looking for good buys. Sometimes they find them. But frequently, they wind up buying stuff they never anticipated buying, and it is merely deposited on a shelf in the basement for future use and is rarely ever heard of any more.

I suppose that I have scores of HF connectors that I wouldn't be able to use if I lived to be a hundred. And God alone knows how many linear feet of shrink tubing and spaghetti, how much stranded #14 copperweld, how many meters, relays, tube sockets, rf chokes, capacitors, resistors, packets of electronic hardware, rubber grommets, nibblers, wire strippers, phone plugs and jacks, test leads, antenna traps, baluns, and other assorted "junk" I have squirreled away in my cellar! Why, I must have ten cigar boxes full of porcelain egg insulators alone!

Almost all of that stuff was bought at flea markets, and I will probably buy a lot more of it in ensuing years.

Tell me something if you can: What makes an otherwise intelligent guy go into the pot for over a dozen lapel badges? I have so many of the danged things that I can never make up my mind which one to wear. But I'll bet that the very next flea market I attend, if one of those birds is there grinding out callsign badges, I'll buy another! I'll see one in a color I don't have or with a couple of flickering LEDs, and there'll go another couple of bucks!

Of course, the worst part is that after you bring this stuff home, you put it in a special place so that you'll be able to lay your hands on it when you have to use it, and then you can't remember where you put it. I'm still looking for a whole box full of zeners that I stashed away for safekeeping about four years ago. I've turned the place upside down and I just can't find them.

Flea markets are viewed by some people as a golden opportunity to unload what can only be described as useless junk. They don't represent it as such, of course; that would be cutting off their nose to spite their face. I wish I had a ten spot in my pocket right this minute for every piece of equipment someone intends to take to a flea market to sell, even though he is quite aware that there is something drastically wrong with it. But this fact will be concealed so that he can "sandbag" some willing sucker. Burned-out transformers, shorted components, kits assembled with wiring errors and cold solder joints, you name it. It's par for the course.

That's why everyone who goes to a flea market ought to remember to bear the old warning *caveat emptor* constantly in mind. Some sponsoring groups have had so many complaints that they have taken to displaying a large sign: "The XYZ Amateur Radio Club makes no warranties in respect to the condition of items bought or sold. All transactions are subject to the discretion of buyers, and the club is neither directly nor indirectly responsible."

But I have another thought, and I'm not at all sure I'm incorrect about it. The good Lord must have made gullible pigeons for some purpose or another, and if they are dumb enough to allow themselves to be taken, it is probably what they deserve.

The reason this postulate doesn't disturb me is that many years of observance and experience have taught me that chiselers cannot cheat anyone who is not himself looking for an opportunity to chisel. Those who believe in dealing honestly are much harder to cheat than those who wouldn't hesitate to pull something a bit shady themselves. If you tend to doubt this, just take a look at the video tapes brought to light in the Abscam mess. Who fell for the sting operation that was set up by the FBI? You don't suppose for a moment that any scrupulously honest senator or congressman would have allowed himself to be enticed into a meeting in some seedy motel room with an Arab oil sheik, do you?

So, by all means, attend flea markets. Buy and sell to your heart's content. And if it should happen that you get stung, well, there's always another one where you might find the buy of a lifetime. I once bought a Collins 32V-2 and had the strange sensation that I was being watched. I opened the rig up and there in the rf cage I found an electrocuted field mouse... his beady little black eyes were open, staring right into mine!

You never can tell what sort of a bonanza you might run into!

RTTY LOOP

from page 18

33 should go up fairly easily, with just about any modern demodulator. I would check the ads here in *73* for something that appeals to you. Anyone who has a 32 on the air might drop George a note at 32-D Martha Drive, Rockland, Massachusetts 02370.

And now, a bit of a tease. I am currently evaluating one of the "new breed" RTTY units. This thing will speak Baudot, ASCII, and Morse at any reasonable speed, convert codes, and store data on tape. Its microcomputer brain is user accessible, so new functions can be devised. One of the cutest is sending SSTV signals with no other equipment! Want a hint? It is made by a company here in the Free State, and it is advertised in *73*. Watch for the full review, as always with both the good and the bad, in next month's RTTY Loop.

OSCAR ORBITS

Courtesy of AMSAT

The OSCAR satellites are subject to atmospheric drag, of course, and the present period of intense solar activity has accentuated the problem. During this period, our sun has been expelling huge numbers of charged particles, some of which find their way into the Earth's upper atmosphere, increasing the density (and thus the drag) there. It is through this region that the OSCARs must pass. OSCAR 8, in a lower orbit than OSCAR 7, is the more seriously affected of the two.

If the drag factor is not considered when OSCAR calculations are performed, long-range orbital projections will be in error. For example, by the end of 1979, OSCAR 8 was more than 20 minutes ahead of some published schedules. The nature of orbital mechanics is such that extra drag on a satellite causes it to move into a lower orbit, resulting in a shorter orbital period. Thus, the satellite arrives above a given Earthbound location earlier than predicted.

Using data supplied to us by Dr. Thomas A. Clark W3IWI of AMSAT, the equatorial crossing tables shown here were generated with the aid of a TRS-80™ microcomputer. The tables take into account the effects of atmospheric drag and should be in error by a few seconds at most.

The listed data tells you the time and place that OSCAR 7 and OSCAR 8 cross the equator in an ascending orbit for the first time each day. To calculate successive OSCAR 7 orbits, make a list of the first orbit number and the next twelve orbits for that day. List the time of the first orbit. Each successive orbit is 115 minutes later (two hours less five minutes). The chart gives the longitude of the day's first ascending (northbound) equatorial crossing. Add 29° for each succeeding orbit. When OSCAR is ascending on the other side of the world from you, it will descend over you. To find the equatorial descending longitude, subtract 166° from the ascending longitude. To find the time OSCAR 7 passes the North Pole, add 29 minutes to the time it passes the equator. You should be able to hear OSCAR 7 when it is within 45 degrees of you. The easiest way to determine if OSCAR is above the horizon (and thus within range) at your location is to take a globe and draw a circle with a radius of 2450 miles (4000 kilometers) from your QTH. If OSCAR passes above that circle, you should be able to hear it. If it passes right overhead, you should hear it for about 24 minutes total. OSCAR 7 will pass an imaginary line drawn from San Francisco to Norfolk about 12 minutes after passing the equator. Add about a minute for each 200 miles that you live north of this line. If OSCAR passes 15° east or west of you, add another minute; at 30°, three minutes; at 45°, ten minutes. Mode A: 145.85-.95 MHz uplink, 29.4-29.5 MHz downlink, beacon at 29.502 MHz. Mode B: 432.125-.175 MHz uplink, 145.975-.925 MHz downlink, beacon at 145.972 MHz.

At press time, OSCAR 7 was scheduled to be in Mode A on odd numbered days of the year and in Mode B on even numbered days. Monday is QRP day on OSCAR 7, while Wednesdays are set aside for experiments and are not available for use.

OSCAR 8 calculations are similar to those for OSCAR 7, with some important exceptions. Instead of making 13 orbits each day, OSCAR 8 makes 14 orbits during each 24-hour period. The orbital period of OSCAR 8 is therefore somewhat shorter: 103 minutes.

To calculate successive OSCAR 8 orbits, make a list of the first orbit number (from the OSCAR 8 chart) and the next thirteen orbits for that day. List the time of the first orbit. Each successive orbit is then 103 minutes later. The chart gives the longitude of the day's first ascending equatorial crossing. Add 26° for each succeeding orbit. To find the time OSCAR 8 passes the North Pole, add 26 minutes to the time it crosses the equator. OSCAR 8 will cross the imaginary San Francisco-to-Norfolk line about 11 minutes after crossing the equator. Mode A: 145.85-.95 MHz uplink, 29.4-29.50 MHz downlink, beacon at 29.40 MHz. Mode J: 145.90-146.00 MHz uplink, 435.20-435.10 MHz downlink, beacon on 435.090 MHz.

OSCAR 8 is in Mode A on Mondays and Thursdays, Mode J on Saturdays and Sundays, and both modes simultaneously on Tuesdays and Fridays. As with OSCAR 7, Wednesdays are reserved for experiments.

OSCAR 7 ORBITAL INFORMATION FOR JANUARY

NEW PRODUCTS

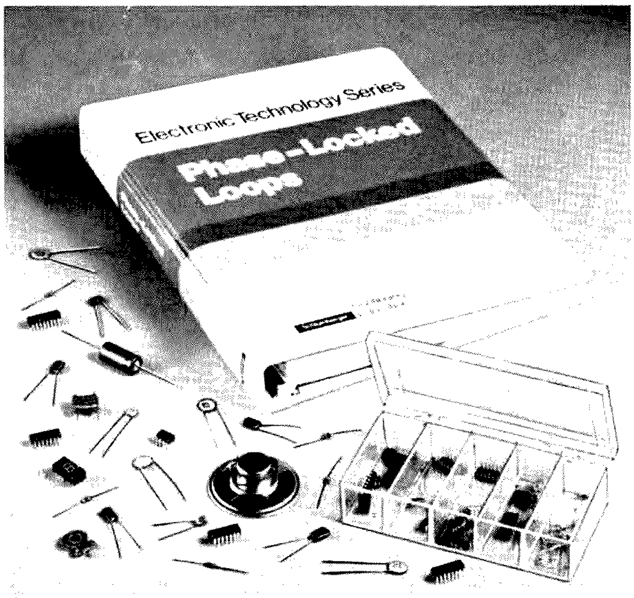
HEATH CONTINUING EDUCATION OFFERS NEW ADVANCED ELECTRONICS PROGRAMS

Heath Continuing Education, a division of Heath Company, has introduced a series of three new learn-at-home electronics programs. Each program covers an advanced electronic subject.

All three programs use programmed self-instruction textbooks that present the subject matter in easy, "bite-sized" segments. They come complete with electronic parts for optional hands-on experiments.

Operational Amplifiers, EE-101, covers the fundamentals of this commonly-used integrated circuit family, including the popular Norton and BiFET designs. The Active Filters program, EE-102, covers the design, operation, and uses of active filters. It describes low-pass, high-pass, bandpass, and state-variable filters, as well as others. The Phase-Locked Loops program, EE-104, discusses the uses, designs, and operation of PLLs. Phase-locked loops are widely used in television receivers, FM receivers, CB and 2-meter transceivers, industrial telemetry circuits, and motor controls.

For further information, contact *Heath Continuing Education, Dept. 350-160, Benton Harbor MI 49022.* Reader Service number 483.



Heath's Phase-Locked Loops program.

BENJAMIN MICHAEL INDUSTRIES' MODEL 173A STATION CLOCK

Benjamin Michael Industries has annnounced the introduction of the Model 173A station clock. The 173A provides the proper 24-hour military time format used by serious communications operators when logging transmissions or verifying contacts and reports. The unit allows the operator to directly read GMT and avoid the confusion created by various local time zones.

The 173A features quartz-crystal accuracy and greater than one year operation from a single penlight battery. Battery operation eliminates the need to reset the clock after power line failures and makes the unit ideal for mobile, field, and emergency power operations.

Time setting is accomplished by the use of two push-buttons and a hold switch which stops the clock operation and resets the internal seconds counter to zero for precise setting to WWV or other time standards. The unit is housed in an attractive aircraft instrument style case.

Benjamin Michael Industries' Model 173A station clock.

For further information, contact *Benjamin Michael Industries, PO Box 173, Prospect Hts. IL 60070.* Reader Service number 480.

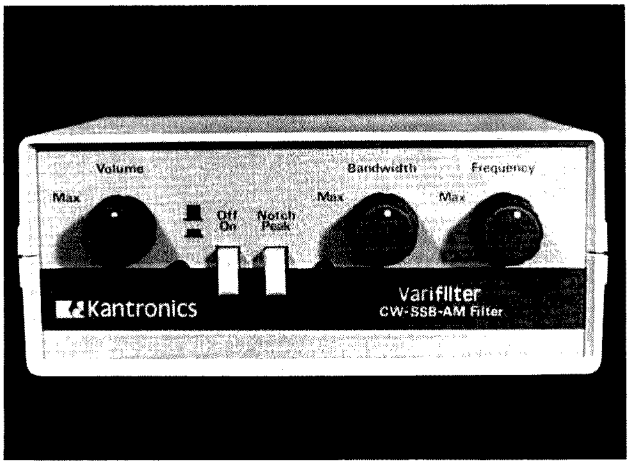
KANTRONICS' VARIFILTER™

You can vary the frequency and the bandwidth of the Varifilter™, a new addition to Kantronics' line of products. The Varifilter can be set to maximize one signal (peaking) or to minimize an interfering signal (notching), and it works with CW (Morse), single-sideband, and AM signals. The Varifilter circuitry is designed to provide optimum results without ringing, oscillating, or instability.

The bandwidth is variable from less than 30 Hz to over 1000 Hz. The frequency range runs from less than 150 Hz to over 3000. Once it has been set, the bandwidth will remain constant regardless of changes in the frequency range setting. This feature has not been readily available in variable filters until now.

The Varifilter has its own internal power supply which is switchable from 115 V ac to 230 V ac. It is able to run from 12 to 18 V dc as well. Each unit has a tuning eye that lets the operator see when he has filtered the signal he wants to.

For further information, contact *Kantronics, Inc., 1202 E. 23rd Street, Lawrence KS 66044.*



Kantronics' Varifilter™.

NEW IC DISPENSERS

OK Machine and Tool Corpor-

ation has introduced its new MDD series of DIP IC dispensers for MOS and CMOS as well as standard devices. The dispensers offer flexibility and convenience to such a unique degree that they are patented. Each channel easily accepts any standard IC shipping tube and can accommodate any standard IC from 2 to 64 pins on .300, .400, or .600 centers.

Adjustable guides position each IC individually for easy extraction, and simple gravity feed ensures reliable deposit of next IC into extraction position after previous IC is removed. Ruggedly made of unique conductive carbon-filled thermoplastic with steel supports, the MDD design ensures effective static dissipation (a grounding lug is included) as well as long and reliable performance. Available in 1-, 5-, and 10-channel versions, the dispensers will greatly facilitate any IC handling or PCB assembly process.

For further information, contact *OK Machine and Tool Corporation, 3455 Conner Street, Bronx NY 10475; (212)-994-6600.* Reader Service number 482.

WRAASE SC-422 SSTV SCAN CONVERTER

The SC-422 is a complete slow-to-fast and fast-to-slow scan converter. It has two full-size SSTV picture memories which can be used either independently to store two different pictures or together for improved picture definition of 256 pixels per line. Received pictures can also be stored in the two memories.

On transmission, a cursor is automatically inserted into the screen, indicating the portion of the SSTV picture being transmitted. The SC-422 allows you to display the fast scan content of the memory, for easy adjustment of the camera. SSTV picture transmission is not interrupted during adjustment of the camera and controls. A built-in SSTV output filter ensures a distortion-free sine wave output.

In the receive mode, a grey scale is inserted at the top of the picture to aid in the adjustment of brightness and contrast controls. An automatic "hold" circuit keeps the most recently received picture in memory when the SSTV input signal stops.

REVIEW

S-F MOD KITS

S-F Radio Amateur Services of Culver City, California, distributes a series of modification kits for the very popular Kenwood TS-820, and makes some pretty impressive improvement claims for them. Both the receiver and transmitter sections are addressed.

The four kits are a front end improvement, a balanced mixer improvement, a "high-power" (QRO) kit, and an rf compressor-to-clipper conversion.

Actually, the compressor-to-clipper modification is not W6TOG's work. It is produced by Magicom of Bellevue, Washington, and is included here with the others because all are related and all are available through S-F.

These kits are *not* inexpensive, ranging in price from $27.50 to $37.50. The total tab for all four is well over $100. Are they worth it? Can the average ham install them? Without reducing the value of the transceiver? Maybe... read on.

The Front-End Modification

The advertising brochure claims rather remarkable improvements in sensitivity, noise figure, and immunity to rf overload. The kit, consisting of two diodes and two transistors, retails for $34.50. The installation instructions are something less than Heathkit® quality, but with a bit of study, they are both adequate and accurate. A disclaimer in large print warns against installation by persons unfamiliar with solid-state circuitry. True, this is probably not a good first project for the beginner, but with ordinary skill and care, installation is not difficult. After all, how hard can it be to remove and install two transistors and two diodes?

Before installation, however, let's do a simple test. With the antenna input terminated to a 50-Ohm load, increase the af gain and check the noise level at the speaker. It is *loud*! With headphones, you probably won't get beyond 12 o'clock without discomfort. All of this racket is internal noise. Make a mental note of the level.

Probably the most difficult part of the installation is finding the transistors to be removed from the foil side of the rf board. The full-size photo in the TS-820 service manual was invaluable. Such a photo would be a useful addition to the installation instructions for the benefit of those who don't have the service manual. Once you find the right pads, removal and reinstallation takes only a few minutes.

The receiver realignment requires no external instruments and goes quickly once you find the right slugs to turn. Again, a photo or sketch with the instructions would be most helpful. Perhaps I'm being too fussy, but I really believe that a few photos or other pictorials might have cut installation time in half.

Does it work? Connect your 50-Ohm load to the antenna terminal, crank up the af gain, and listen to the internal noise again. Listen carefully, because there's not much noise left to hear. As for sensitivity, an improvement from 0.25 microvolts to 0.09 microvolts is claimed. I don't have the instrumentation to measure it, but there is an improvement. The original TS-820 used to run neck and neck with my SB-303 on weak-signal performance. Now, especially on 10 meters, the TS-820 hears signals that just aren't there on the SB-303.

The Balanced Mixer Mods

I was so pleased with the results of the front-end improvements that I decided to go ahead with the balanced mixer mods. This kit retails for $27.50 and consists of two more transistors and several resistors. A substantial improvement in immunity from rf overload is claimed to result. This is particularly important to me, since I live within 500 feet of another ham who runs full legal power, and I've become accustomed to the distinctive sound of my S-meter needle pounding the pin on top of the scale. We simply can't operate simultaneously on the same band.

For practical purposes, installation is just about the same as the front-end kit. The actual parts replacement takes less time than locating the parts to be removed, and, once again, a picture would be most helpful. If I had to do the job again, I surely would install both kits at once, since the rf board would have to be removed only once, and ditto the receiver realignment.

This time when you listen for internal noise, listen very, very carefully. In my installation, there is virtually none. It was so quiet I was almost afraid the radio wasn't working. On the air, weak signals just seem to pop out of an almost silent background. More recently, this advantage has been lost to a noisy power line, but certainly not through any fault of the balanced mixer mods.

I wish the rf-overload problem had gone the same route as the internal noise, but not quite so. However, the situation is very much improved. I now can hear a relatively weak signal 10-15 kHz from the local ham's transmit frequency, and this is at least as much as I expected. We still can't operate the same band at the same time, but that's because I still do the same number on his receiver that he used to do on mine.

The QRO Kit

This kit retails for $37.50, and consists of two 6293 tubes and several small components. The 6293 is a ruggedized version of the 6146 and is a direct pin-for-pin replacement. This modification consists of two separate operations. One involves raising the screen voltage, and the other changes the ALC time constant for better action.

The first part of the modification couldn't be easier. Move a wire, install two resistors, and replace the finals. A note of caution here—neutralize the new finals quickly! I turned on the radio to warm up and went to look for a non-metallic tool to make the adjustment. The new finals were so far out of neutralization that I returned just in time to see the fuse blow from all the plate current being drawn from self-oscillation. This may be an isolated case, but be careful anyway. The finals went downhill with the fuse and I thought I might have an expensive problem, but the folks at S-F solved that one by replacing the tubes at no charge. They are good people to do business with.

The ALC modifications involve finding and replacing a resistor, a diode, and a capacitor on the rf board. These components are located in a less dense section of the board than the front end and balanced mixer. Thus, the job is relatively easier, even without pictures. This is another task that could easily be worked in with the front-end and balanced mixer mods, so that only one removal of the rf board would be required.

As it came from the factory, my TS-820 delivered 100 Watts output on 160 and 80 meters, 100 Watts on 40 through 15 meters, and less than 80 Watts on 10 meters. With the QRO mod, output was increased at least 25 Watts on all bands and nearly 35 Watts on 10 meters. Still more power is available by using 220 volts ac rather than 110. This brought output to 170 Watts on 160 and 80 meters, 150 Watts on 40 through 15, and an honest 140 Watts on 10 meters. Simply changing to 220 volts ac probably would have made a noticeable improvement even without the QRO kit. Also noticeable is the much faster ALC recovery.

The Magicom

This unit is a preassembled circuit board about two inches square, which sells for $27.50. It converts the stock rf compressor to an rf clipper. While I have no reason to believe there is any connection, there is a striking similarity to the Magnum Six available a few years ago.

The Magicom board installs on the i-f board in a relatively open area near the crystal filter(s). If you have additional crystal filters installed, or have plans to do so, you may wish to consider relocating either the filters or the Magicom. Installation consists of removing two capacitors and connecting four leads from the Magicom.

The instructions warn that careful workmanship and sufficient study of the work are required. This is good advice. Parts density on the i-f board is high, and great care certainly is required. In this case, an exploded view of the foil side of the board is provided with the instructions and is worth its weight in gold. When the appropriate pads are found, installation is a snap.

Once installed, the Magicom lives up to its claims, but first a few words about my goals and expectations with respect to speech processing. I am not an

audio purist. I am a DXer. It's not nearly as important to me that the DX station enjoys the sound of my voice as it is that he can understand my call letters through a pileup. I'm perfectly willing to sacrifice tonal fidelity for penetrating intelligibility.

As it turns out, I sacrificed nothing with the Magicom. The same audiophiles who complained that my audio sounded "harsh" and "overprocessed" now report that it sounds much better. At the same time, the DXers who reported "weak" or "muffled" audio now find it to be far more penetrating.

So, is the whole thing worth it? If all your time on the air is spent rag chewing with solid-copy stations, it certainly is not. The stock TS-820 (and many other radios) will do the job very nicely without the extra expense and work. Strictly in terms of dollars per components, the price is steep. If you could identify all the components, you surely could buy them for a lot less. But remember, you're buying more than components. You're paying for many hours of someone's research and experimentation. For me, it's worth every penny.

Can the average ham install it? I think so. My technical skills are well on the low side of average. To provide a reference point, there's a local joke about the W4LVM School of (backward) Diode Installation. On the other hand, if you have difficulty recognizing a diode, maybe you should forget about it.

One distinct advantage is the absence of external signs of modification. There are no holes, nothing outboard, nothing to detract from resale value. In fact, the whole operation is easily reversible should you wish to do so. I don't ever plan to reverse it. In fact, if S-F should offer additional mods, I'll probably be one of the first in line.

For further information, contact *S-F Amateur Radio Services, 4384 Keystone Ave., Culver City CA 90230*. Reader Service number 477.

AED SCANNERS

You have undoubtedly heard of Murphy's Law. OK, but have you heard of Orozco's postulate? I thought not! Well, simply stated, it says that the degree of dissatisfaction with one's own

rig is directly proportional to the number of visits to the local candy store. As we watch the microprocessor come of age, we realize that if a particular rig exists, then it is obsolete! Only what is on the drawing boards is state of the art. If your transceiver doesn't have two vfos, six memories, three scanning modes, and the ability to poach your morning eggs, then it just isn't up to date!

Sad, but true. You drive home, looking at your once-current mobile rig, noticing its plain face and lack of dials and lights... how could this happen so fast! You say it will only transmit and receive? How quaint...

Enter AED Electronics and their line of scanners. Don't send old Dobbin to the glue factory just yet... I purchased one of these scanner boards from a local dealer and headed home with great expectations. No creeping obsolescence for me!

Installation

On closer inspection, the board itself is not at all complicated and probably does not warrant the extra expenditure to purchase it fully assembled. Beyond that, all installation and operation instructions are both complete and easy to read. The circuit board is tailored to fit in your particular radio with no modification whatsoever. A few wiring connections to the rotary frequency-control switch and to the PLL section were all that were required. I had only to decide for myself where to put the two toggle switches that control the scanning functions. There was even a provision for older transceivers that had only the two-position power switch. About an hour later, my Midland 13-513 was ready for the time-honored smoke test. Lo and behold... no cold solders or miswired leads!

Operation

The scanner for the Midland 220 rig is very easy to operate and does its job very well indeed. There are two switches that control the operation of the microprocessor chip. The first switch either leaves the rig operating normally or puts it in the scan mode. The second one allows it to scan the MHz section selected or will stop it on the current frequency to transmit or receive. That's all there is to it. While scanning the section of the band selected, it will stop for about eight seconds on any frequency that will break the squelch, giving you time to lock it there if you wish. If you don't, it will continue its scan *ad infinitum*. On my unit, the return time to a particular frequency, barring any interruption, is about 16 seconds more than sufficient to catch the action. As warned in the instructions, you must set the frequency to zero-zero (i.e., 224.00) to have it scan normally. Yes, I tried it with a random frequency in the window, and yes, it scans... but quite erratically. So much for experimentation!

Conclusions

I feel that this unit is a particularly valuable addition to the Midland 13-513, due to the fact that fully-synthesized 220 rigs are hard to find. This scanner increases the capabilities of an already very capable radio. Frequency scanning is well suited to the 220 band because of the long periods of silence encountered when monitoring just one frequency. It lets you monitor practically the whole band and participate when and where you wish. I am finding frequencies that I never knew existed. Have you ever heard someone say, "Let's QSY to the other one," and wonder where they went? Never again. Now, let's see... how can I squeeze another vfo into this case?

For More Information

These units are available for a wide range of 2-meter and 220 transceivers, and the price range starts at $39.95. Scan rates, frequency coverage, and switch functions and configurations will vary from model to model. More information can be obtained from *AED Electronics, 750 Lucerne Rd., Suite 120, Montreal, Quebec, Canada H3R 2H6.* Reader Service number 476.

AEA CK-1 MORSE MEMORY KEYER

For some time now, Advanced Electronic Applications, Inc., has been producing some unique and rather exciting products for the radio amateur. Whether the device be an autodialer, an antenna, or an electronic keyer, AEA's products have been injected with a healthy dose of careful research and solid engineering. The company's latest offering, the CK-1 Morse Memory Keyer, is certainly no exception. In a case just barely larger than a typical calculator, we are given a keyer with almost every feature that the dedicated or even not-so-dedicated CW operator could ask for. While it is perfectly possible to put the CK-1 on the air without ever opening the instruction book, you'll want to read and even reread the manual a few times in order to be able to take full advantage of the keyer's capabilities. Once you've figured everything out, you'll never want to part with it!

The first thing you notice about the CK-1 is its apparent simplicity. On top, there is a standard twelve-tone touchpad; it gives a reassuring tactile response to each entry, and an audio confirmation as well, through the tiny but adequate speaker which also is mounted on top. The only other control topside is the combination on-off switch/volume control. Be careful! When you turn the unit off, you erase everything you have programmed into the keyer's memories. Fortunately, AEA assures us that the keyer is designed to be left on continuously.

On the left side of the case is the only other switch on the keyer; this selects either the memory-send or the memory-load mode. On the opposite side of the keyer is a non-shorting, power-input jack.

AEA specifies the unit as requiring 12 V dc ± 3 volts, which is quite reasonable in light of the fact that everything but the side-

tone amp is powered through an on-board 7805 regulator chip. On the back side are found two jacks. One is a DIN plug for input from a keying paddle, and the other is a phono jack for keying a transmitter. As it comes from the factory, the CK-1 is set up for negative keying. If you have a transistorized rig that requires positive keying, don't panic. On the first page of the manual, AEA outlines a simple modification that will allow the keyer to work with your rig. The mod consists of soldering a jumper across a diode inside the keyer. I had the mod completed and the CK-1 happily keying my Icom 701 in five minutes; even the least technically minded among us should have no problems with this one!

Hooking up the paddles is equally simple. Some hams might prefer to see the more standard phone plug used for the paddle input, but space considerations inside the CK-1 don't permit that. Besides, the DIN plug *is* a rather neat arrangement; maybe the Europeans know something we don't!

Once everything is hooked up, the next step is to turn it on. On power-up, the CK-1 is set for 20 wpm with fully-automatic iambic operation, dot and dash memories, and standard weighting. Each of these functions can be selected or rejected individually at your whim, all by entering the proper code through the touchpad. The most eccentric operator can set up this keyer to his personal taste quickly, with the digital-entry method providing a precision and repeatability of adjustment that is impossible with the knobs found on more traditional keyers.

For now, let's assume that you are content to operate with the standard operating parameters, but find the speed a bit too fast for your taste. No problem. The CK-1 offers two methods of changing speeds. If 20 wpm is too fast, you press the " * " button once and then hold down the "7" button. What will greet your ears is a dihdahdihdahdihdah pattern, with each dihdah being a bit slower than the one which preceded it. When it reaches the speed you have in mind, you simply lift your finger off the keyboard and commence operation. If you want to speed up, you follow the same procedure,

Emergency Tone Alert System

During the last part of July, 1979, tropical storm Claudette hit the Galveston-Houston area, dropping from ten to forty-five (yes, forty-five) inches of rain in various parts of the region in a very short time. Although the area was well blanketed with repeaters carrying emergency information, the rapid rise of water at night caught many hams unaware; some did not know of the emergency until water started coming into their homes. At that time, there was no way of alerting the radio amateurs once they went to bed, since most of them turned off their two-meter rigs so that the routine chatter on the frequency would not keep them awake.

Claudette made it extremely clear that a method was needed to quickly and efficiently alert area amateurs that an emergency situation existed. Two additional emergencies in rapid sequence made it imperative that we act immediately.

Our need was for a simple, economical system that could be put into effect almost immediately. Discussion on the air and at the August meeting of the Tidelands Amateur Radio Society (TARS) and the University of Texas Medical Branch (Galveston)-Emergency Communications Group (UTMB-ECG) developed criteria for a device similar to the tone-alert system of the National Weather Service (NWS), a single-tone system.

Photo A. Completed tone alert.

A system for decoding dual tones has been used in Dallas for the past two years. Of the approximately 400 Radio Amateur Civil Emergency Service (RACES) members in Dallas, one hundred have the tone alert available. The usual response to any use of the emergency tone alert is at least 50% of the hams equipped to receive it. The local authorities are very impressed with the ability of the hams to respond to emergencies. The Dallas system is the "A-Tone Decoder" using the DTMF A tone. The tone alert is initiated by Civil Defense. Initially, the alert is on the 146.28/.88-MHz repeater, but it may go to other repeaters if the area of emergency is wider than can be covered by one repeater. The choice of the A tone for this metropolitan area was based upon the high possibility for abuse of other tones. The A tone generally is not available on the pads commonly used by hams. So far, Dallas has had no false alerts, even though some non-hams have gotten access to two-meter equipment and some hams have tried to jam the

transmissions.

Tarrant County (Fort Worth), near Dallas, is interested in implementing a similar system in the near future.

The decision of TARS and UTMB-ECG was to develop a tone-alert device based upon the success of Dallas, the ideas expressed by WA3ENK,[1] the WB5PRD design, and utilizing at least a four-second signal of the dual tones of the DTMF figure 9 (which most amateurs have available in a touch-tone™ or comparable pad) as the triggering signal. Use of a relay to silence the audio circuit to an external speaker until activated by the tone was considered the simplest alert device. The four-to-five-second duration of the tone in our tone alert causes a relay to close which then turns on an external speaker or alarm bell.

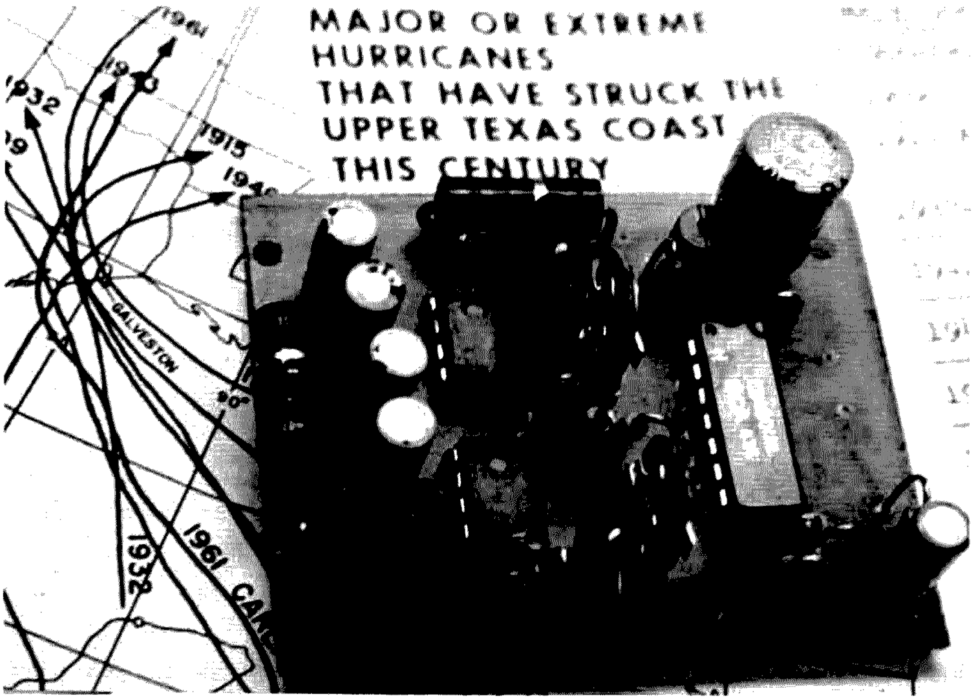

Photo B. Assembled PC board.

Twenty copies of the original WB5PRD board were ordered, and within three days the interest was so great that an additional 50 boards were ordered.

The original WB5PRD schematic was modified (but still using the original board) to fit our needs and to use the DTMF 9 tones. Local sources of parts in quantity were inadequate, so parts were ordered to provide 50 tone-alert kits. Parts were ordered from companies advertising in the several amateur radio journals. Upon checking the parts when they arrived, we found one company had shipped 30% of the parts in an inoperable condition, so these had to be replaced. By careful selection of sources, we were able to get the total cost (parts and board) down to $12.50 for each kit. (The prototype using parts bought in small quantities was built for about $18.00.) While awaiting receipt of parts, a construction and testing manual was written.

Word of what we were doing spread rapidly and inquiries came from other clubs and groups. Discussions concerning this system became quite active among several RACES and CD nets in Houston, Alvin, Clear Lake, and East Texas areas. Several groups asked if the device could be adapted to their special needs.

The concept of TARS and UTMB-ECG calls for the Emergency Operating Centers (EOCs) or a duly-authorized operator to initiate the 9 tone whenever the need arises to activate the net for emergencies. We also use the tone alert to call up our weekly repeater (147.75/.15 MHz) and simplex (145.53 MHz) nets.

As others have discovered, in the absence of phone-patch capability, hams must rely on tone alert.[2] It soon became apparent that two levels of alert would be needed: a low-level alert for personal emergencies such as car trouble, and a high-level alert for general emergencies such as hurricanes, floods, or explosions. A single-tone capability for low-level alerts can be added without additional circuitry, using a toggle switch to ground one decoder output. With the switch in the low position, the tone alert can be activated by a DTMF 7, 8, or 9. We recommend the use of the figure 7 for low-level alerts and reservation of the figure 9 for high-level alerts.

Generally, the amateurs leave the tone alert on low level when they are around the shack and switch to high level when they go to bed. Thus, their alert device would awaken them only for high-level general emergencies.

Several other groups are planning to use the 9 for their alerts. Thus, a number of hams are now using the tone alert with scanners monitoring these several repeaters. The scanners are being modified so that they will scan silently even if there is routine activity on the frequency, but if the 9 signal is given, the scanner will lock onto that frequency and activate the audio.

The Texas DX Society is considering using the tone alert on their repeater to alert members when rare DX is heard on the HF bands. They anticipate using a set of tones other than the 9 so that their signal will not activate scanners that are monitoring the repeaters for emergencies.

Another modification of the tone alert will be for use with weather radios to decode the 1050-Hz tone of the National Weather Service alerts and activate weather receivers not previously provided with tone alert. Since the NWS alert is only a single tone, such use will require only one decoder of the tone alert. The tone alert used for NWS cannot be used at the same time for the DTMF emergency tones.

Why were the 9 and 7 tones chosen? We thought that since 911 is used on the telephone to dial emergencies to fire and police, use of a 9 would be easy to remember as the alert sig-

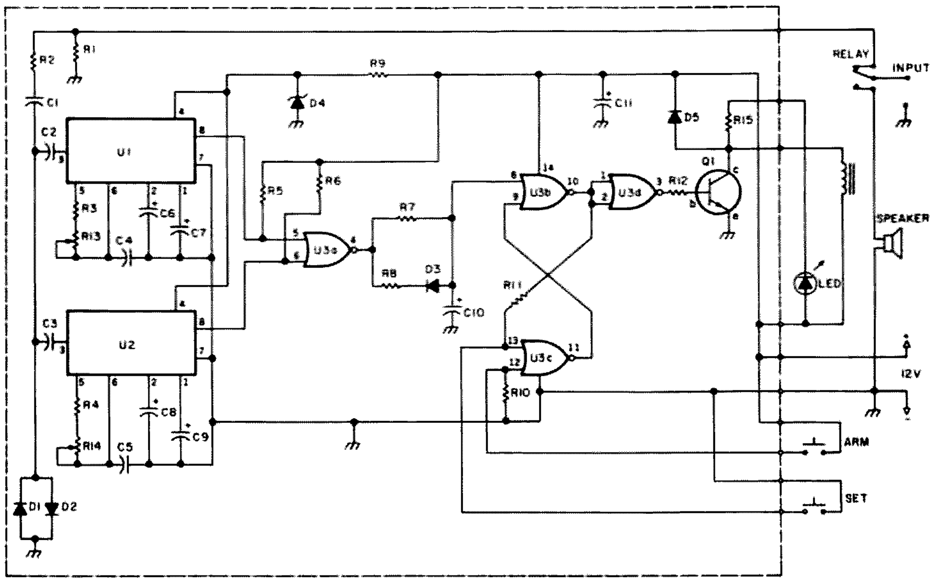

Fig. 1. Schematic diagram. (See Parts List.)

nal. The low-level alert is a good-neighbor service for individual or personal emergencies; therefore, it was considered appropriate to use the 7 or 73 for this alert tone.

Whether a large area such as the Galveston-Houston area is involved in emergencies or smaller local areas only, there is a way to alert only one or the other. If a general alert is involved, then the alerting operator goes from repeater to repeater giving the alert and announcing the emergency. If only a local area is involved, then only the repeater covering that area is alerted.

Because of the seriousness of emergencies that can occur in this region of the Gulf Coast and the potential for abuse, it was early decided to establish the following Galveston County general guidelines for use of the tone alert.

High-Level Alert

1. The tone alert will be activated only by duly-authorized operators acting on behalf of emergencies declared by Civil Defense or other official agencies, or on behalf of the repeater organization.

2. Alert will be sounded:
   a) in the event of a civil emergency;
   b) for a regularly scheduled test or drill;
   c) to call attention to bulletins of general interest during an emergency.

3. Initially, the alert will be sounded on the repeater (147.75/.15 MHz) covering the area affected by the emergency and on 145.53 MHz simplex.

4. Alert will be sounded by transmitting the digit 9 for 15 seconds. The station transmitting the tone will:
   a) identify;
   b) transmit tone for 15 seconds;
   c) call CQ or QST;
   d) state the nature of the emergency or that a test or drill is in progress;
   e) give instructions concerning action to be taken and/or frequencies to be monitored.

5. Individual testing and tune-up of the tone-alert circuit will be done on a simplex frequency other than 145.53 MHz and will not be done on repeaters. Use low power if possible when testing or tuning circuit.

6. High-level tone alert will not be used for routine personal emergencies such as flat tire, out of gas, etc.

Low-Level Alert

1. This alert may be sounded by any amateur having a personal or individual emergency for which he needs help. (It is recommended that a direct call on the repeater or simplex frequency be tried first before using the tone alert.)

2. Low-level alerts will be sounded only on the local area simplex or repeater frequency. Low-level alerts are not to be used for general alerts covering more than one repeater.

3. Alert will be sounded by transmitting the digit 7 for 15 seconds. The station transmitting the tone will:
   a) identify;
   b) transmit the 7 tone for 15 seconds;
   c) call CQ or QST;
   d) state the nature of the emergency and request the necessary assistance.

This plan has been operational since August, 1979, is gaining adherents, and the idea is spreading. Based upon our experience, we would recommend this or a similar system to other amateurs participating in emergency activities.

Circuit Description

The schematic is shown in Fig. 1. The components listed in the Parts List are standard items which are readily available. Advantages and disadvantages of the 567 PLL tone decoder have been discussed previously in the amateur literature.[3,4]

The circuit is powered from a 12-volt dc source. Zener diode D4 provides 6.2 volts dc for U1 and U2.

When the circuit is armed by bringing pin 12 of U3c to logic one briefly, audio is routed through the normally-closed contact of the relay to loading resistor R1 and to the input of the decoder circuits through R2. Germanium diodes D1 and D2 conduct at 300 mV to protect the circuit from audio overload. C2 and C3 pass the audio tones but block dc from entering U1 and U2 along with the audio signal.

U1 and U2 decode the high and low tones, respectively. R3, R13, and C4 set the center frequency of U1; R4, R14, and C5 set the center frequency of U2 (bandwidth is about 5% of the center frequency).

When a decoder locks on an incoming tone, pin 8 goes to logic zero. When both U1 and U2 are locked, pin 4 of NOR gate U3a goes to logic one. C10 then charges through R7 to provide a delay before pin 8 of U3b reaches logic one. U3d inverts the output of U3b. The sequence is now complete, the relay and LED are activated by Q1, and audio is now routed to the speaker until the circuit is again armed.

A total delay of three to four seconds is introduced between initial reception of the tone and activation of the relay to prevent false activation of the circuit.

D3 and R8 provide a discharge path for C10 when no tone is present. This prevents a buildup of charge over a period of time from intermittent false signals which might cause activation of the circuit. D5 protects Q1 from the transient voltage present when the relay is deactivated.

Momentarily closing the normally-open ARM (RESET) switch will deactivate the relay (open the audio circuit to the speaker) and will arm the decoders so that they can respond to an incoming tone signal.

Momentarily closing the normally-open SET switch will activate the relay so that audio goes to the speaker. This mode will continue until the ARM (RESET) switch is activated. (A momentary DPDT toggle switch with center off can be used in place of two separate momentary switches.)

Assembly

The circuit was assembled on a WB5PRD circuit board. (Drilled printed circuit boards are available from WB5PRD for an SASE and $4.00.) The foil side of the board is shown in Fig. 2, which is suitable for use in reproducing the board. An assembled PC board and a completed tone alert are shown in the photographs.

Parts layout is shown in Fig. 3. Assembly can be facilitated if one starts with those components at the center of the board and works outward toward the edge. Diodes, capacitors, trimpots, and quarter-Watt resistors are mounted vertically. The two one-Watt resistors are mounted horizontally. If proper care is taken as to which end of the vertically-mounted resistors is upmost, then that point of the resistor can be used as a test-point contact for testing other parts of the circuit. (See Table 1.)

The usual precautions should be observed when handling the 4001 CMOS integrated circuit. For temperature stability, C4 and C5 must be high-quality mylar™ or metallized film capacitors.

The switches and LED are installed on the front panel or speaker enclosure. The LED should be near the SET switch; the LED lights when the tone-alert unit is in the SET activation. The relay is installed off the circuit board with epoxy glue or silicone rubber. A multi-pole relay may be substituted if other devices, in addition to the speaker, are to be controlled. (Remember that when other devices such as bells or buzzers are on the relay, they will be activated when the SET switch is activated.)

The twelve-volt dc supply is connected between points marked + and − (ground). One side of the relay coil and the LED anode are connected to point K&L and the other side of the relay coil goes to K. The cathode of the LED goes to L. The ARM (RESET) switch is connected to the points marked A. The SET switch is connected to the two points marked S. Audio is connected between INPUT and ground. Points E, B, and C indicate the emitter, base, and collector of Q1.

Tune-Up

The tone alert may be adjusted for the DTMF tone 9 using either of two procedures—either a frequency counter or a voltmeter may be used. With the frequency counter method, the counter is connected to U1 at pin 5 (for a square wave) or pin 6 (for a triangle wave), and R13 is adjusted until the counter shows 1477 Hz. Take care not to load the circuit with the test equipment. Next, connect the counter to pin 5 or 6 of U2 and adjust R14 until the counter shows 852 Hz.

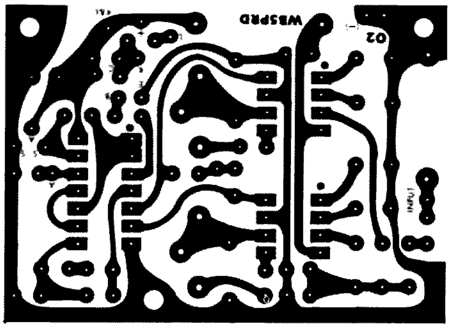

Fig. 2. PC board, foil side. This is suitable for reproducing the board for those who would like to do so.

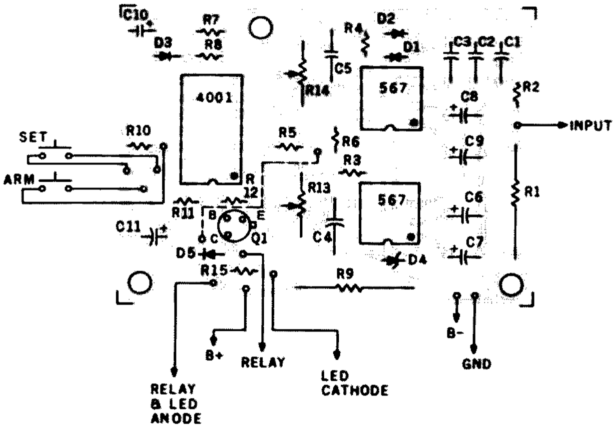

Fig. 3. Parts layout.

Alternatively, a voltmeter or logic probe may be used. Start with R13 and R14 fully counterclockwise. Apply an alert tone with the probe on pin 8 of U1 or pin 5 of U3 and slowly turn R13 clockwise. Note the position of R13 when the voltage drops and continue turning R13 clockwise until the voltage goes back up; note this point. Turn R13 counterclockwise to a point midway between the two voltage change settings. Do the same with the probe on pin 8 of U2 or pin 6 of U3 while adjusting R14.

Operation

Apply 12 volts dc to the unit. Momentarily close the SET switch; the relay should activate. Provide an audio input from the two-meter rig. The circuit will not function properly with a high noise signal or with too little audio drive. Turn the audio gain up to ensure proper drive level. The loading resistor is rated at one Watt. ARM the circuit and have another operator transmit an alert tone on a simplex frequency for fifteen seconds. The unit should activate in less than ten seconds.

Circuit Alternatives

The circuit can be tuned for tones other than the digit 9. The standard tone pairs are listed in Table 2.

Component	Connection
R3	Pin 5, U1
R4	Pin 5, U2
R5	Pin 5, U3a
R6	Pin 6, U3a
R7	Pin 8, U3b
R8	Pin 4, U3a
R11	Pin 2, U3d
R12	Pin 3, U3d

Table 1. The end of the component connected to the listed test point is placed in the up position.

Low Tone	High Tone 1209 Hz	1336 Hz	1477 Hz	1633 Hz
697 Hz	1	2	3	A
770 Hz	4	5	6	B
852 Hz	7	8	9	C
941 Hz	*	0	#	D

Table 2. DTMF tone pairs. Each digit or sign is composed of two tones. For example, 1 is composed of a 697-Hz tone and a 1209-Hz tone.

Low Tone (Hz)	R4 (kilohms)	High Tone (Hz)	R3 (kilohms)
697	11.0	1209	5.6
770	10.0	1336	5.6
852	8.2	1477	5.6
941	8.2	1633	3.9

Table 3. Alternate values for R3 and R4.

4001 Pin	Set	Armed	Tone Present	U1 and U2 Pin	Voltage
1	Low	High	—	4	6.2 V
2	Low	High	—	5	12.0 V (no alert tone)
3	High	Low	—		0.1 V (alert tone present)
4*	Low	Low	High		
5*	High	High	Low		
6*	High	High	Low		
7	---------Ground pin---------				
8*	Low	Low	High		
9	High	Low	—		
10	Low	High	—		
11	High	Low	—		
12**	Low	Low	—		
13	Low	High	—		
14	---------12 volt pin---------				

*These remain at the same state during SET and ARMed periods and change only during the presence of the alert tone. Do not replace the chip yet if any of these pins do not agree.
**This pin should go high while pressing the ARMed button.

Table 4. Logic and voltage chart.

Parts List

Resistors
R1—10 Ohms, 1 Watt
R2—1.5k Ohms, ¼ Watt
R3—5.6k Ohms, ¼ Watt
R4—8.2k Ohms, ¼ Watt
R5, 6, 11—27k Ohms, ¼ Watt
R7—560k Ohms, ¼ Watt
R8—1k Ohms, ¼ Watt
R9—220 Ohms, 1 Watt
R10—10k Ohms, ¼ Watt
R12—22k Ohms, ¼ Watt
R13, 14—5 kilohms, vertical trimpots
R15—1k Ohms, ¼ Watt
Capacitors
C1, 2, 3—0.1 μF ceramic disc, 25 V
C4, 5—0.1 μF mylar™, 16 V
C6, 8—1.0 μF electrolytic, 6 V
C7, 9—10.0 μF electrolytic, 6 V
C10—3.3 μF electrolytic, 16 V
C11—100 μF electrolytic, 16 V
Semiconductors
D1, 2—1N34A germanium (or equivalent)
D3—1N914 silicon (or equivalent)
D4—6.2 volt, 400 mW zener
D5—1N4001 (or equivalent)
Q1—2N2222 NPN transistor
U1, U2—567 dual inline, tone decoder
U3—4001 CMOS logic block
Keep CMOS wrapped in foil until ready to install.
LED—jumbo LED of choice

The corresponding alternative values for R3 and R4 are shown in Table 3.

Most of the delay between the introduction of an alert tone and relay activation is introduced by R7 and C10. These may be adjusted to provide a longer or shorter delay.

If one wishes to have both a low level of alert and a high level of alert, this can be done by adding an SPST toggle switch so that pin 5 of U3a (or pin 8 of U1) can be grounded. With pin 5 or pin 8 grounded, only a single tone (852 Hz) will activate the unit. With the switch in the closed (grounded) position, the tone alert can be activated by the digit 7 for a low-level or personal emergency, and in the switch-open position, it will take both tones of the digit 9 to activate the unit.

Weather Watch (Alert) Modifications

Only minor changes are required on this circuit to decode the NWS 1050-Hz alert tone for weather radios that do not have this feature. U1, R3, R5, R13, C4, C6, and C7 are omitted. A jumper is placed between the foils originally intended for pins 7 and 8 of U1. R14 is adjusted for 1050 Hz at pin 5 or 6 of U2. Activation methods and time will remain the same.

Troubleshooting

Step One: Most problems with performance can be traced to bad solder joints, solder bridges, incorrect parts placement, or failure to observe polarity of diodes or capacitors. All construction steps should be retraced with this firmly in mind.

Step Two: Confirm that adequate noise-free audio is actually present at the input and that the relay will work out of the circuit. Close the SET switch to activate the relay.

Step Three: Use a VTVM or FET-VOM (at least a megohm resistance) and check the voltages listed in Table 4.

Step Four: Using a piece of hookup wire, connect one end to ground and carefully touch the other end to both pins 5 and 6 of U3 with the circuit ARMed. The relay should activate in about four seconds. If it takes as long as thirty seconds to activate the relay, check R7, R8, C10, and D3. If this fails, replace U3.

Step Five: Check U1 and U2 for proper tuning.

Step Six: Ground pin 8 of U1 and send a DTMF digit 7 signal over the audio input. If this activates the relay in 4-6 seconds, then U2 is tuned and functioning. If the relay does not activate, then replace U2 and try again.

Step Seven: Ground pin 8 of U2 and send a DTMF digit 3 signal over the audio input. If this activates the relay in 4-6 seconds, then U1 is tuned and functioning. If the relay does not activate, then replace U1 and try again. ■

WWV-to-80-Meter Converter

This simple and inexpensive frequency converter will place the WWV 10-MHz signal anywhere within the 80-meter band. Credit for the basic design goes to PM Electronics, a local firm that is now defunct.

Referring to the schematic in Fig. 1, L1-C2 are tuned to the WWV 10-MHz signal. This signal is coupled to the base of Q1 by L2. Oscillator Q2 operates at any selected crystal frequency between 6 and 6.5 MHz, and is coupled to the emitter of Q1 by C7. Q1 mixes the two frequencies. The L3-C5-C6 combination is tuned to the 3.5-to-4-MHz difference frequency which appears at the collector of Q1. Impedance matching to the 50-Ohm receiver antenna is provided by the C5-C6 capacitive divider.

Crystal frequency is determined by subtracting the desired 80-meter frequency from the WWV 10-MHz frequency. The 3750-to-3800-kHz range (6250-to-6200-kHz crystal) might be a good choice for minimum signal interference. The crystal may be obtained from Jan Crystals, 2400 Crystal Drive, Ft. Myers FL 33906. Specify type FT-243 holder and desired crystal frequency. This crystal will be .005% tolerance. Jan's 1980 catalog (#23) lists this crystal at $2.00 each with a 30-cent per crystal handling and first class mail charge. The FT-243 socket, part SSO-1, also may be obtained for an additional 30 cents.

The circuit board can be quickly and easily made by first positioning and securing the copper face of a 1-3/4" × 3-3/8" board under the circuit pattern in Fig. 2. Next, mark through the pattern at each hole location and then drill a #60 hole at each mark. The inductor pin and crystal socket holes may require pattern adjustment and larger holes. Also, check the lead spacing of your capacitors. The layout is for 1/4-inch spacing but room is available for the 3/8-inch variety.

Finally, carefully connect the related holes with 1/8-inch strips of art or masking tape. Place masking tape over the component side of the board to prevent acid from entering the holes. Thoroughly clean the copper surface after etching. Using this method, I easily etched and assembled a checkout board in one afternoon.

The inductors are wound on a 1/4-inch diameter slug-tuned coil form as shown in Photo A. These may be found in most junked TV sets and radios. As viewed from the base, coils L1 and L2 are wound counterclock-

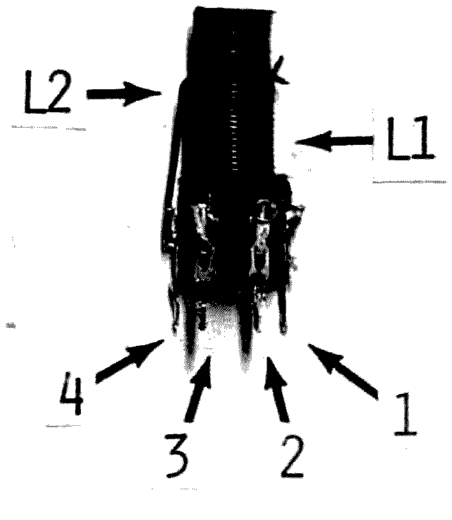

Photo A. Close-up of the L1-L2 inductor. L1 is 12 ccw turns and L2 is 4 ccw turns of #24 enameled wire. L3 is 35 cw turns of #32 enameled wire. All inductors are wound on a 1/4-inch slug-tuned coil form.

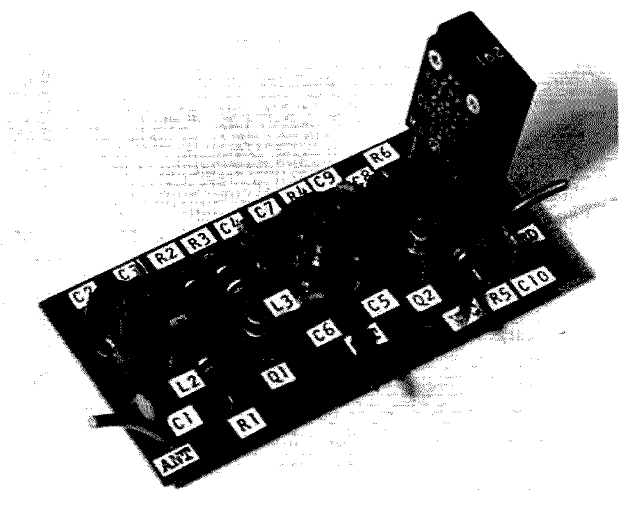

Photo B. Top view of the completed WWV-to-80-meter frequency converter.

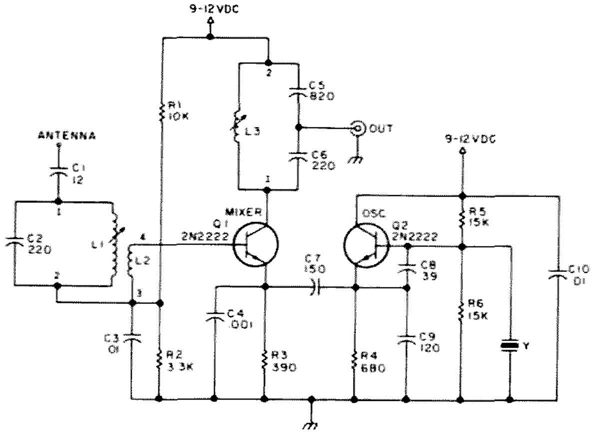

Fig. 1. Schematic diagram of the WWV converter. Resistors are 1/4 or 1/2 Watt. Capacitors C3 and C10 are Mylar™, with all others being disc ceramic.

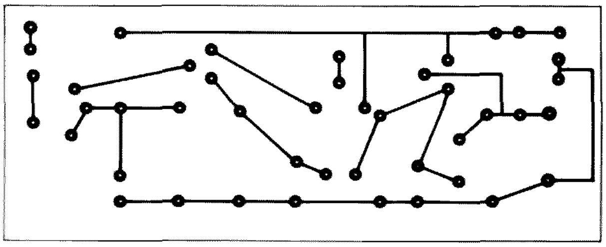

Fig. 2. Foil side of the circuit board.

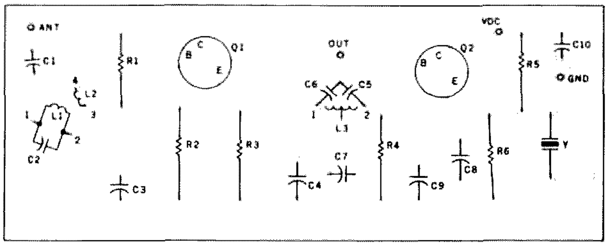

Fig. 3. Parts placement guide (foil side shown).

wise with #24 enameled wire, and L3 is wound clockwise with #32 enameled wire. All three inductors are wound with no space between turns. L2 begins at the end of L1 with no space between the end of L1 and the start of L2. Secure the coil ends with thread or tape and apply two or three coats of varnish to hold the coil in place.

Capacitors C2, C5, and C6 are soldered directly to the inductor pins. I tried several sets of transistors, both NPN and PNP types, and they all worked. Just reverse the voltage polarity for PNP types. To align, connect a short antenna and set L1 and L3 for maximum S-meter reading with a nonmetallic tool. Use shielded cable for hookup to the receiver.

My thanks to Chuck Allyn, who so kindly provided the photographs for this article. If you have a question or need parts help, an SASE will bring a prompt reply. ■

Cheap and Simple

—your basic 13.8-V, 25-A power supply

The 13.8-volt ham radio transceiver has really come of age. Many of these units are great for mobile operation, but when it comes to fixed-station use, the transceivers can really come up short—primarily because of the comparatively high current values they draw on peaks.

The two-meter FM and police-scanner industries have given us a variety of 13.8-volt, low-current power supplies which in many cases can be bought more cheaply than built. However, the seemingly rarified 13.8-volt, fifteen-Amp (or higher) power supply is not that easy to come by, which really limits the possibilities with transceivers drawing anywhere from sixteen to twenty Amperes.

Scanning the catalogs became a depressing experience for me, particularly when supporting one wife, three cats, and twelve hobbies on a pilot's salary. There are a number of excellent commercial power supplies available, but you can expect to pay an absolute minimum of $100 for low-current versions and as much as $300 for a power supply beefy enough to keep my Vibroplex Presentation dancing its way through the kilos and megas. Besides all that, my idea of a power supply is something that sits in a darkened corner, is not seen, and is purely an accessory to my equipment. $100? $200? $300? For a lousy power supply?

Occasionally, a magazine article has slipped through on the subject of 13.8-volt, high-current power supplies. Unfortunately, in many cases the authors have escaped the world of simplicity and featured components and techniques that are available easily only through NASA. Hence, I drew up a priorities list so that I could readily view my criteria for such a power supply: 1) cheap, 2) simple, 3) cheap, and above all, 4) cheap. I am one of those chicken-wire and chewing-gum types whose home-brewed projects are best characterized as "functional" and are best unseen. (At least with power supplies, anyway.)

My particular need was to supply power to an Atlas 210X. While my home station is basically a salvage yard for old boat anchors, six years or so ago I pressed the Atlas into mobile service. In fact, mobile operation is all my Atlas has ever seen. Until recently it has

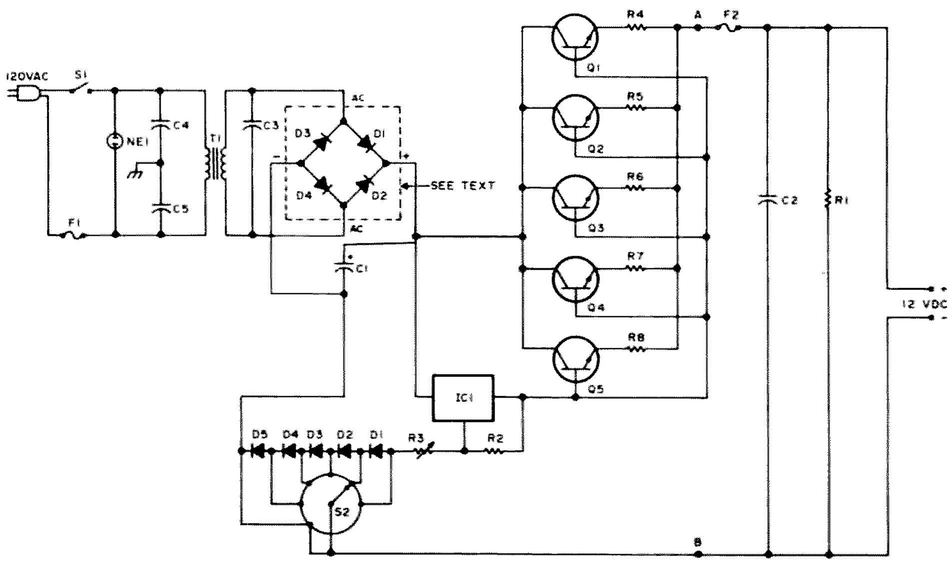

Fig. 1. Power supply schematic diagram.

never known the joy of taking a spike from the ac mains. Besides, with a dc supply, I could haul the 210X into the motel room, run coax out to the bumper mount, and dit-dah my eyeballs out.

Why not carry around a car battery and trickle charger, you ask? Too messy and cumbersome. Another option was to buy the factory-built console/power supply, but I heard rumors (only rumors) that the console/power supply left a little to be desired in the regulation department.

The Circuit

The power-supply circuit uses 2N3055 transistors. You can tailor your current capability by the number of pass transistors you use. I wanted a 25-Amp supply, so I used five 2N3055s. You can figure roughly one transistor for every 5 Amps you'll be drawing. In a 10-Amp supply, only two transistors would be used, and so on.

The 2N3055 is an NPN power device built into a TO-3 case. The 3055 is one of the more easily come by transistors and is very cheap (meeting criteria 1, 3, and 4). Because of the power these little devils are going to be dissipating, heat sinks should be employed. I used a heat sink with approximately 27 square inches of surface area with four half-inch fins, which cools nicely. Extreme heat can quickly mess up the transistor junction (not to mention a nice paint job). Before securing the transistors to the heat sink, apply some silicone thermal compound between the 3055s and the surface of the heat sink to provide a good positive heat transfer.

I have always used the rule of thumb that if you can't touch it, you can blow it. If you don't care to go heat-sink shopping, use a cooling fan. If you use a fan in addition to the heat sink, be sure the air circulates in line with the fins. Blowing air perpendicularly to the fins sets up standing waves—the aerodynamic kind—and turbulence and the cooling effect is minimal.

Transistor-mounting hardware is nice, but I didn't feel that it was necessary. I attached the transistors directly to the heat sink and then mounted the whole heat-sink assembly on a sheet of Plexiglas™ attached to four standoffs. Since the transistor case is common to the collector, I tapped a screw into one of the heat-sink fins and this became my common collector tiepoint. It is important to keep all lead lengths constant. After drilling matching holes for the base and emitter pins in the heat sink, heavy-gauge wire was soldered (carefully) to each emitter pin through a 0.25-Ohm resistor, and then a second piece of wire was attached to each base pin. I then had only to connect the rest of the circuit to either the heat sink or one of the two bus wires.

You may or may not have difficulty locating a suitable transformer capable of taking 120 V ac and squeezing it down to 17 to 24 V ac. I was lucky enough to locate an old, beat-up, ex-battery-charger transformer at a hamfest which gave me 120/17 V ac. I think you will find old battery chargers to be a good source for the transformer you will need. Remember, the transformer must be capable of carrying the current you are going to draw from your power supply. I paid $3.00 for my transformer and felt robbed; I have seen them for a dollar. Yes, you do take a risk, but remember, even if the transformer is no good, it is an excellent source of #14 AWG antenna wire (or larger)!

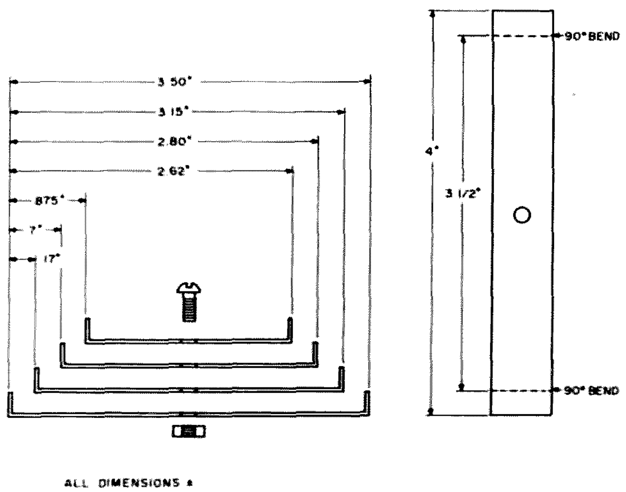

Fig. 2. Heat sink construction details.

In the rectifier circuit there are two avenues to follow. You can buy four diodes and make your bridge or you can do as I did and use one of the nifty one-inch-square epoxy bridge rectifiers. The little one-inch jobs are convenient because you don't have to mess around figuring which end is the anode and which is the cathode. Ordinarily, the epoxied bridges are simply marked AC, AC, +, and −. Can you beat that?

As always, no matter what you do for rectification, be sure your rectifier is rated for the current you will be needing. Most of the little square bridges are rated between 20 and 35 Amps. I am using a Semtech-Alpac 7905 only because I happened to have one on hand. Motorola, International Rectifier, VARO, and EDI make excellent equivalents.

Voltage regulation depends on adequate filtering and an IC known as a 7812. After much experimentation, I found that my voltage regulation (as well as hum attenuation) improved as I increased the value of filter capacitor C2. Starting out with 2000 uF, I worked my way upward to 13,000 uF. Though I now have a 37,000-uF filter capacitor in the circuit, 13,000 uF seemed to be enough. The amount of filtering achieved by going from

Parts List

C1—13,000-uF, 25-V electrolytic capacitor
C2—10-uF, 25-V electrolytic capacitor
C3—0.22-uF, 100-V tubular capacitor
C4, C5—0.01-uF, 500 V ceramic capacitor
D1-D4—25-A diodes or epoxy bridge rectifier (see text)
D1-D5—1N4004 diodes
F1—Fuse, 5 Amp
F2—Fuse, 30 Amp
Q1, Q2, Q3, Q4, Q5—2N3055 transistors
R1—120-Ohm 4-W resistor
R2—3000-Ohm, ½-W resistor
R3—500-Ohm, 1-W potentiometer
R4, R5, R6, R7, R8—0.25-Ohm, 1-W resistor
IC1—7812 voltage regulator
S1—SPST switch
S2—6-position wafer switch
T1—120/17-24-V ac power transformer (see text)
Miscellaneous: NE1 neon bulb, binding posts, line cord, 0-25-V dc voltmeter, 0-30-A ammeter, heat sinks, chassis, blower, fuseholders, and bulb socket.

13,000 to 37,000 uF is very, very slight and detectable only with a scope. Obviously one can't ignore the thought that if 13,000 uF is good, a higher value would be better, but let me caution you enthusiastic high-capacity freaks against installing 150,000-uF capacitors without limiting inrush current. I haven't experimented beyond 37,000 uF.

The 7812 voltage regulator is an IC device capable of maintaining excellent regulation as long as the input voltage falls between 14.6 and 19 volts nominally. A number of companies are producing the 7812 and it generally has some sort of prefix or suffix, but the digits remain the same.

In this circuit, the 7812 is above ground through a 200- to 500-Ohm resistor. I don't put an exact value on this because it is not that critical. Going from receive to full-output transmit on my Atlas (300 mA to peaks of 16 Amperes), the voltage drop on the power supply is 0.4 V, which ain't bad. Since I normally don't run my equipment at full bore, the drop from receive to transmit is quite small.

As was the case with the pass transistors, I mounted the 7812 on a heat sink affixed to a small piece of Plexiglas on standoffs (to simplify its isolation from the chassis). The heat sink (see Fig. 2) is made of four strips of one-inch-wide aluminum cut at varying lengths and bent up a half-inch at each end. I then placed each one "inside" a larger one until, voilà, La Heat Sink a la Cheap. To keep the strips aligned, a hole was drilled which also served to attach the 7812.

While it isn't necessary, you can build in a selectable voltage feature by connecting any number of 1N4004 diodes on a wafer-type switch. This switch goes between pin 3 of the 7812 and ground. (If this seems like a lot of hooey to you, you may disregard the above and connect pin 3 of the 7812 to ground through R3. You will see a voltage change of approximately 0.7 V with each position on the switch. With my supply, I have the capability of as much as 15 V or so, and the switch permits me to "switch down to" the proper voltage I desire (13.8 V dc).

The value of bleeder resistor R1 across the output is not critical either, but have something there for your protection.

By varying the resistance of R3, your output voltage will vary considerably. I believe a potentiometer instead of a fixed-value resistor is a better route so that more flexibility is available for future voltage needs which now might not be considered. As in my case, if you are receiving 16.8 V from your transformer, 250 Ohms is sufficient to yield the 13.8 V dc you want.

Should you be supplying your rectifier with 16 to 18 volts and not be getting a stable 13 volts or so, check to be sure that you are not losing (dropping) all of your voltage in your rectifier diodes or epoxy bridge. Some of the epoxy bridge rectifiers are poor in the area of voltage consistency. Try a different one, even of the same manufacturer. Another place to watch for voltage losses is in your wiring. The more current you draw, the higher your voltage drops may become in your transformer, rectifier, filter capacitor, or wiring. Wire which is too small may cause substantial voltage drops. I would suggest using #14 AWG wire at least.

H-u-m-m-m-m

My first test of the power supply was disastrous. Not only was the regulation terrible, but the audio was 80% hum, 20% ham. Two things lead to the elimination of hum: First (and already covered), I placed my voltage regulator above ground on the Plexiglas support; second, I connected all of my chassis ground connections to one point.

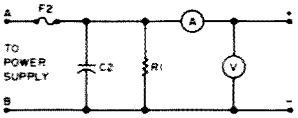

Fig. 3. Power supply metering arrangement.

As with my other home-brew endeavors, I first mounted the power supply on an open chassis. Breadboarding can save you much agony when it comes time to actually fitting the darned thing in a permanent box. Scouting around at the Dayton Hamvention, I was able to come up with a perfect cabinet (which formerly was a microvolt meter) for $1.00. When shopping for an enclosure, don't overlook old, non-working test equipment, etc.

Metering can be added easily as shown in Fig. 3. (When will the price of meters ever come down?)

The cost is going to vary depending on the state of your junk box and what kind of hamfest bargains you can locate. I spent more than I really wanted to, and that was slightly over ten dollars. You can't beat the pages of *73 Magazine* for bargains on the components used here; it was from there that I purchased all of my purchased parts.

As you build this, take your time. Do a good job. Dress all of your leads. Use red wires for + and black wires for −. Take time to consider the aesthetics of this project. Then tuck it away in a dark corner and ignore it, because it's only a stupid power supply. ■

Direct Printing FAX

—part III: testing and operation

In this third and last part of this article, I will cover preparation, testing, and operation of the facsimile recorder.

Initial alignment will require a frequency counter, a VOM, a logic probe, and a source of video—either a live signal from the receiver, a recorded signal, or the test generator of chapter 7 in the *Weather Satellite Handbook*. In the following sequence of tests, we will gradually add ICs to the board as each stage is tested. In *all* cases the unit should be powered down prior to inserting new integrated circuits. Damage to specific chips can results if you attempt to insert them with the board powered up. Preset the controls as follows:

POWER—OFF
WHITE SET—minimum (max. CCW)
VOC ADJ—midrange
DRUM—OFF
RESET/STANDBY/PRINT—STANDBY

The following checks are associated with the particular chips added to the board as we move along. If problems are encountered at any step, you should check the board wiring around the specific chips, measure the supply voltages on the chips themselves, and try a replacement IC if it seems necessary.

1) Power up and measure the unregulated power supply voltages. You should get about 24-28 V from the LV supply and anything from 250-350 is acceptable on the HV bus. +5 and +12 volts should be obtained at the appropriate main board buses and the POWER lamp should be on.

2) Insert U3 and connect the frequency counter to pin 5 of this IC. Power up and adjust the VCO ADJ control for a reading of 2400 Hz.

3) Insert U4. The logic probe should indicate a high on the collector of Q6.

4) Insert U5 and U6. Connect the probe to pin 6 of U5 and use a test lead to momentarily ground the IC side of R21. The logic probe should indicate a relatively long pulse. Move the probe to pin 6 of U6 and again short the IC side of R21 to ground—a much shorter pulse should be indicated.

5) Insert U7. Press the PHASE switch and the PHASE ERROR lamp should come on and stay on. Use the test lead to ground the IC side of R21, and the PHASE ERROR lamp should go out.

6) Insert U8 and connect the logic probe to pin 8 of U8. With the PHASE ERROR lamp off, the probe should indicate a steady high as the IC side of R21 is grounded with the test lead. Use another clip lead to ground the transistor side of R19. Press the PHASE switch and the PHASE ERROR lamp should come on and stay on even if you ground R21. The probe should indicate a short low each time R21 is grounded. Remove the clip lead from R19—the PHASE ERROR lamp should go out the next time you ground R21 and the probe should indicate a steady logic high from that point on.

7) Insert U9, U10, U11, and U12. The following frequencies should be noted as the counter is moved to the indicated ICs:
U9 (pin 8)—2400 Hz
U10 (pin 12)—240 Hz
U11 (pin 8)—60 Hz
U12 (pin 8)—60 Hz

8) Connect the VOM across the 115-V windings of T202 and set the instrument for ac volts (120-V min.). Turn the drum switch on and advance the DRUM LEVEL control for a reading of 110-115-V ac. The drum should now be rotating away from you as you look at it from the carriage side. Momentarily pressing the MANUAL PHASE switch should cause the drum to slow slightly. It should stop if you keep the switch depressed.

9) With the drum revolving, connect the logic probe to pin 6 of U6 and a steady string of short, high pulses should be noted. If they are not present or are erratic, alter the position of the reed switch until you get a steady pulse indication. Depress and hold the PHASE switch and note the PHASE ERROR lamp. It should be on but should blink off very briefly once for each drum revolution. Release the PHASE switch and the PHASE ERROR lamp should go off at once. Turn off the DRUM switch.

10) Temporarily disconnect the TRAVERSE cable. Set the VOM to dc volts (350 min.) and connect the positive lead to the stylus probe. A reading of 240 V (±10%) should be obtained when the RESET/STANDBY/PRINT is cycled to PRINT. No voltage should be noted with the switch in the RESET or STANDBY position. Return the switch to STANDBY.

11) Connect the TRAVERSE cable and cycle the RESET/STANDBY/PRINT switch to PRINT. The carriage should begin to move away from the traverse motor. If the switch is cycled to RESET, the drive nut should begin to move back toward the traverse motor. Leave the switch in the STANDBY position and unplug the TRAVERSE cable.

12) Connect a source of video to the VIDEO INPUT jack. Unless otherwise noted, all of the following adjustments will be made during the phasing interval preceding picture transmission. This interval is a steady 2400-Hz tone, interrupted by the short phasing pulses. Insert U1 and U2.

13) Temporarily connect a speaker from the negative side of C7 to ground. Advance the WHITE SET control and you should hear an undistorted reproduction of the video signal. As the video level is increased, cycle the RESET/STANDBY/PRINT switch to PRINT and monitor the stylus voltage. (Each time you check the stylus voltage, the switch should be in the PRINT position. Keep it in STANDBY between these measurements to avoid the possibility of a shock hazard.)

14) As the WHITE SET control is advanced, the stylus voltage should gradually decrease and the meter indication should bounce up very slightly with each phasing pulse. Continue to advance the WHITE SET control and you should reach a point —between 25 and 35 volts —where the voltage will drop no lower. Retard the WHITE SET control to the point where you first reach this low-voltage threshold. If you watch the voltage during actual data transmission, it will fluctuate between the low and high voltage limits.

15) Observe the VCO LOCK lamp—it should light whenever video is applied to the input and should remain lighted throughout a frame transmission.

16) Connect the logic probe to the collector of Q6 and adjust R14 for a steady stream of logic highs during the phasing interval.

17) Turn the drum on and press the PHASE switch at the completion of the start tone. The PHASE ERROR lamp will come on and you may be able to hear a slight difference in the sound of the drum motor, indicating that it has slowed slightly. The lamp should go off sometime within about 15 seconds, depending upon the initial phase error.

At this point, all the major systems have been checked out. The last remaining step is to prepare the wire stylus and condition it. Cut one of the wires from a wire brush (one intended for use in an electric drill) and straighten it with a pair of needle-nosed pliers. The wire need not be completely straight, as some remaining curvature will assist in holding it in the stylus holder. Insert the wire into the protruding stylus tubing and trim the end so that it extends about 1/16" out of the end of the tube. Wrap a piece of fine emery paper around the drum and secure it with transparent tape. Rotate the stylus assembly such that the wire contacts the emery paper, and observe the orientation of the wire. If it is tilted slightly, it should be tilted in the direction of drum movement—that is, it should point toward the back of the drum. If it points toward the front of the drum, remove the wire and reinsert it so that it is tilted in the proper direction. Turn the drum and allow the stylus to run in contact with the rotating emery paper for a period of 30 seconds or so. The end of the wire will be quite rough initially, but you should be able to hear a considerable difference in sound as it smoothes out under the abrasive action of the paper. Remove the emery paper and prepare for the moment you have been waiting for—your first picture!

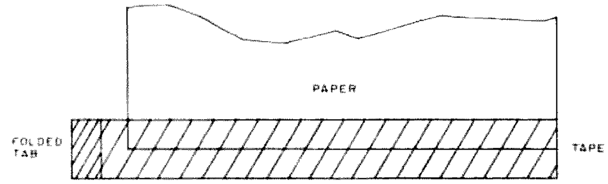

Fig. 1. Paper preparation and manipulation. The tape is placed along one edge of the paper as shown. The opposite edge is then inserted under the aluminum foil strip on the drum and the drum is rotated to wrap the paper around the drum. The edge of the paper with the tape will then completely overlap the foil strip and the tape can be smoothed down to secure the paper to the drum. Removal of the paper is accomplished by lifting the small tab at the end of the tape strip and carefully peeling the tape away from the paper surface. A strip of tape can be reused several times if handled carefully.

Operation

Three different papers have been used to date, all of which work quite well, although there are some advantages to one over the others. The preferred paper is that manufactured by Xerox® for their Telecopier™ office facsimile machines. Contact the nearest Xerox office and request reorder number 3R830. The paper is 8.5" × 11" and comes in packages of 150 and 500 sheets. The cost is lower in 500-sheet lots, and you can save still more by ordering two boxes of 500 sheets at one time.

A paper equal to the Xerox is Timefax NDK, manufactured by Fitchburg Coated Paper Products of Scranton PA. The main difficulty is getting Fitchburg to supply the paper in small lots. They have yet to prove the least bit cooperative, and the Xerox paper is much easier to obtain. If you can get the Timefax NDK, it will do an excellent job.

3M, Inc., of Minneapolis MN makes a similar paper for its line of office fax machines, and the price is in line with that of Xerox. While it will do a good job, I have found the 3M paper to be somewhat smokey in operation and it doesn't seem to yield as nice a gray scale as the Xerox paper despite the claims of the sales reps. It is quite possible that it functions best at a slightly lower maximum printing voltage, so I wouldn't say to avoid it if it is the easiest paper for you to obtain. You might try substituting a 100-V zener for D5 to bring the printing voltage down to 220-V maximum if you plan to use the 3M paper.

All of the papers come in the standard 8.5" × 11" size and must be cut down to 7" × 7" for use on the recorder. A small office paper cutter set up with wooden stops is the fastest way to cut the paper to size. With a good cutter, you can slice up to 10 sheets at a time.

Loading the Paper. The printing side of the paper is the smooth white surface —the back looks slightly mottled and is a little rougher in texture. Lay the piece of paper—printing side up—on a table and strip off a piece of transparent tape (the high-quality translucent variety is best) about 7.5" long. Fold over one end to make a little tab so that you can strip

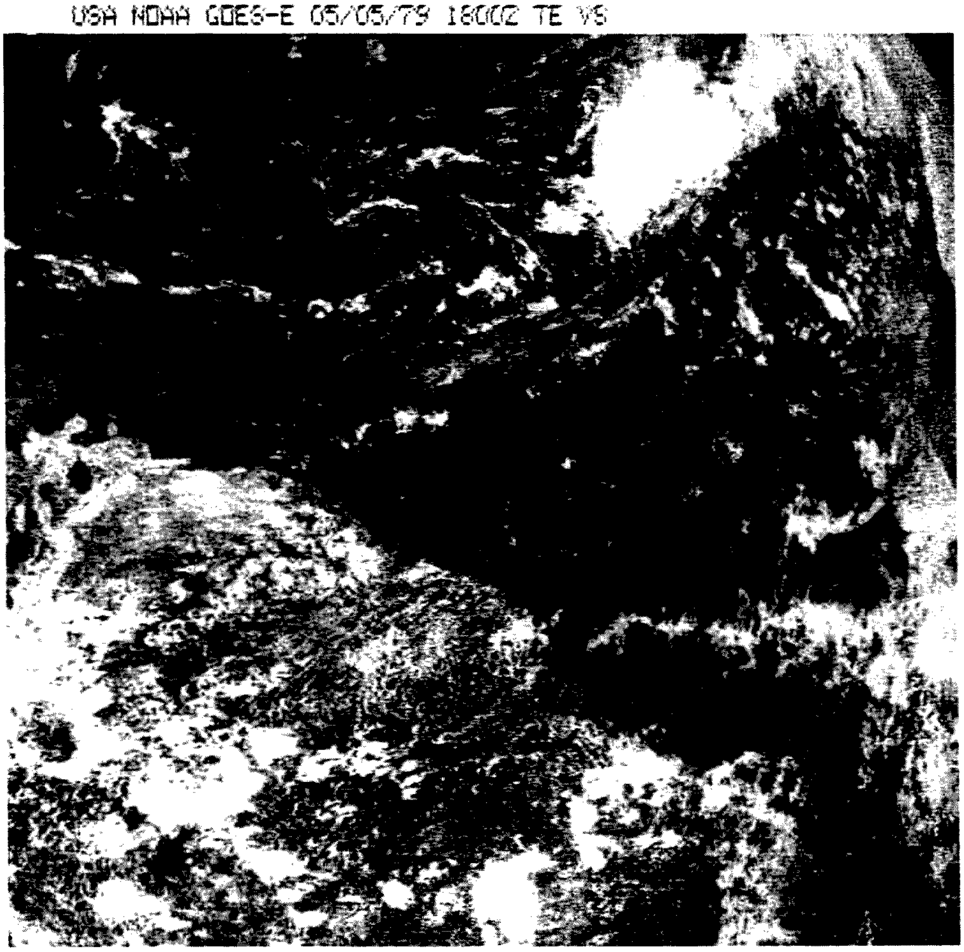

Fig. 2. An example, from a GOES E Tropical East quad, of the excellent resolution obtained with the FX-2E direct-printing recorder. These fine cloud details could be resolved with a photographic system, but extreme care in focusing the light gun would be required. The direct-printing option, because a wire stylus is used, always yields optimum resolution without the need to worry about focusing the system.

the tape off later. Lay the tape over one edge of the paper as indicated in Fig. 1.

Cycle the RESET/STANDBY/PRINT switch to RESET until the drive nut reaches the right end of the drive rod. Slide the edge of the paper opposite the tape under the folded strip of foil and, holding the paper against the drum with your fingers, rotate the drum away from you, wrapping the paper around the drum. When you get all the way around, the paper should overlap the foil strip and you can smooth down the tape to secure the paper to the drum.

Position the carriage so that the stylus rests just inside the right margin of the paper. Remove the stylus from the paper and cycle the switch to PRINT. The drive nut will move back toward the carriage. Guide the brad over the base of the carriage and cycle the switch to STANDBY when the drive nut starts to move the carriage. Rotate the stylus assembly to place the stylus back on the paper and you are ready to go.

Printing. When the GOES carrier comes on, turn on the drum. At the completion of the start tone, press the PHASE switch. Sometime within about 15 seconds of this action the PHASE ERROR lamp should go off, indicating the drum is in phase with the incoming signal. Twenty seconds after the end of the start tone, cycle the RESET/STANDBY/PRINT switch to PRINT. When the frame starts, you should be able to see the effect on the drum as the stylus moves along. When the stop tone arrives, cycle to STANDBY, stop the drum, remove the stylus, and take off your picture by carefully stripping off the strip of tape. If you put the tape carefully aside, you can use it for quite a few prints.

Optimizing. If this is your first print, it is not likely to be perfect—it probably will be too light. To optimize the WHITE SET control, start the printing during the phasing interval and carefully watch the paper as you back off the WHITE SET control. The optimum setting is where you can just see the slightest darkening of the surface at the printing stylus.

The reset procedure can be shortened somewhat by locating the proper start position for the carriage and running the drive nut up against the carriage as noted. Slide the carriage away from the nut and use india ink to mark the glass where the brad contacts it. In the future when you reset the drive nut, simply run it back to the mark you have made and then you can move the carriage up against it, knowing that the stylus is properly located.

Operation with TIROS/NOAA or METEOR Imagery

A triggered oscilloscope is used to phase the incoming picture when the FX-2E is used to display pictures from polar-orbiting spacecraft. Connect the TRIGGER jack to the scope trigger input and the VIDEO OUT jack to the scope vertical input. What you will get is a video waveform display triggered by the fax drum. With a little experience, you will be able to recognize the position of the line sync pulses on the scope display. Set the recorder up as described and when the signal is solidly out of the noise and with the drum running, simply press the MANUAL PHASE switch in short bursts until the line sync pulse is aligned with the left edge of the scope display. At this point, the RESET/STANDBY/PRINT switch can be cycled to PRINT until the carriage reaches its limit of travel.

Alternatively, if you have built the CRT monitor of chapter 4 of the *Weather Satellite Handbook*, you can use it for phasing display. Connect the video input to the monitor in parallel with that of the fax and

lift the diode connected to point B in Figure 4.6 of the *Handbook*. Connect the TRIGGER output to this point, and the monitor display will now trigger from the fax drum. In practice, it is easiest to install an EXTERNAL TRIGGER jack to the back of the monitor, connected to the TRIGGER output of the FX-2E. An SPST toggle switch (INTERNAL/EXTERNAL TRIGGER) can then be added so that you have switch-selection of either internal or external triggering. The internal position is used for normal monitor operation or when the fax drum is not running (saving wear and tear on the horizontal deflection transistors), while the external position is used to manually display and phase the fax. To use the monitor in this fashion, you should reset the fax carriage and load paper as instructed. Start the drum, and switch the monitor to EXTERNAL TRIGGER. When the signal is out of the noise, you can start the monitor sweep and operate the MANUAL PHASE switch of the FX-2E to move the line sync pulse (either visible or IR) to the left edge of the viewing area. At that point, you can start the fax printing.

Fig. 3. Direct-printing readout of a GOES E operational message, showing the excellent printing clarity which is obtained.

Operation as a Photographic Facsimile Recorder

The only electronic changes for photofax operation include the following:

1) Delete R9, R10, D5, D6, Q2, and R11.

2) Replace R8 with a 100-Ohm pot, which will serve as a BLACK SET control.

3) Add a 15-mA meter in the switched 300-V line.

4) Connect an R1130B glow modulator tube from the collector of Q1 to the 350-V bus, with the 15-mA meter in series. Rewire S201A so that the lamp is energized (connected to the 350-V line) with the switch in the PRINT position.

5) Reverse the diodes (D1-D4) in the detector, delete R7, and replace it with a 2200-Ohm resistor connected between the base of Q1 and the +12-V bus.

Refer to either the first edition of the *Weather Satellite Handbook* or the September and October, 1975, issues of *73* for construction of the light gun and its mounting to the carriage. The phase-sensor reed switch will have to be reoriented so that it closes just as the edge of the photographic paper passes the light gun lens.

With no video input, adjust R8 (BLACK SET) for a meter reading of 15 mA with S201 in the PRINT position. Full video drive (white level) should then be applied and the WHITE SET control adjusted for a reading of about 1 mA. Resin-coated enlarging papers are recommended for printing, with Kodak Kodabrome RC being preferred (normal contrast grade). Black and white level adjustment should be altered in practice to produce good prints when the paper is processed for 2 minutes in Kodak Dektol developer. Any commercial fixer may be used, and you should consult your local photographic supplier for trays, chemicals, safelights, etc. The aluminum foil strips and ground connections will not be required on the drum and can be omitted. When used in the photofax mode, the recorder must be operated in a darkroom with suitable safelight illumination to protect unexposed paper. The paper can be cut to the required 7" × 7" in the darkroom.

Although the recorder will produce superb photographic prints, I have not operated it in the photographic mode since first setting up the direct-printing version (see Figs. 2 and 3). The fax system is certainly somewhat more complicated a project than a CRT monitor, primarily due to the mechanical aspects of the project. Once finished, however, it should give you years of trouble-free service. The prototype of the photographic facsimile version has been in operation for over two years without a single problem, and there is no reason to assume that the direct-printing version will not have the same reliability. The FX-2E system is virtually ideal in that it provides for easy operation, low operating costs, immediate availability of good-sized prints, superb resolution, and photographic image quality. ■

Unplug It, Dummy!

—safety for the traveling ham

For those recreational vehicles which have provisions for connecting to 110-volt outside power, there is always the risk of the owner forgetting to unplug the power cord before driving off. Human frailty and Murphy's Law being what they are, this is bound to happen sooner or later.

For us, the reckoning came one time when we had our camper van parked in our driveway while we were packing for a trip. We had the cord plugged into our house power for precooling the refrigerator. Getting off later than we had hoped, we took off in a hurry. When we got to our first stop, we were horrified to find the socket from our extension cord sitting in the van power receptacle. The cord had pulled right out of its socket when we drove off, meaning it was lying in our driveway with the live ends exposed. Mindful of the neighborhood children who frequently play in our driveway, we put in a frantic long-distance call to our local police, informing them of the situation and asking them to do something about the hazard. Fortunately, no further harm came of it.

To preclude any repetition of this fiasco, I installed a cord alarm in our van. It is arranged so that a door bell rings if the ignition is turned on while the cord is plugged in. You can install such an alarm in your RV for an expenditure of about $15 for parts—less than the cost of a power cord that might be ruined by a drive-off. It does the same job as a commercial alarm that sells for $50.

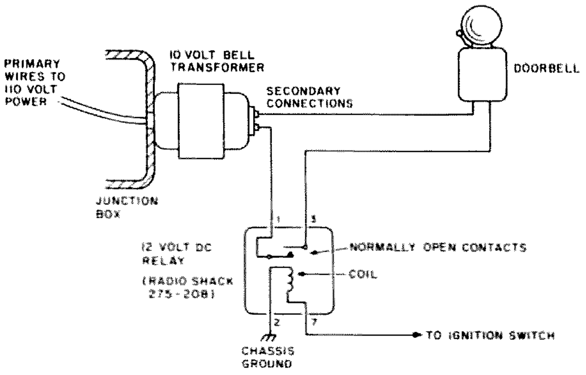

Fig. 1. Wiring diagram of the cord alarm.

You will need the following three items: (1) An ordinary door bell, installed near the driver's seat. I chose a door bell rather than a buzzer in order to have a distinctive alarm sound that would not be confused with the seat-belt warning buzzer. (2) A bell transformer of the type designed to mount in a knockout hole in a junction box. Be sure to get a 10-volt transformer rather than a 16-volt type, which is for chimes. (3) A 12-volt dc relay (Radio Shack #275-208 or equivalent).

Attach the bell transformer to an unused knockout hole in the power control center or the junction box for the outside power receptacle. (Confinement of the 110-volt wiring to the inside of such a box makes for a very safe installation.) Connect the primary wires to the 110-volt power at the point where it enters the vehicle, with no circuit breakers or other switching devices intervening so that the alarm will not fail to operate because of a breaker or switch being turned off. (Protection against short circuits in the transformer is given by the circuit breaker feeding the outlet into which the cord is plugged.)

Make a bracket for the relay socket out of sheet metal or aluminum angle and mount the relay in a convenient location. Wire up the system as shown in Fig. 1, soldering all connections to the relay socket. The transformer is connected to the bell in series with a pair of normally-open contacts on the relay. One end of the relay coil is connected to chassis ground, and the other end is connected to a circuit that is energized when the ignition is turned on. Pick a circuit that is energized only in the "ignition" position of the switch, and not the "accessory" position. For our Econoline van, a convenient connection point was the wire feeding power to the seat-belt warning system.

With these connections, turning on the ignition operates the relay and completes the circuit from the transformer to the bell so that it will ring if the transformer is powered by the cord being plugged in.

What if you remember to unplug the cord but forget to stow it? This alarm is foolproof but it is not claimed to be *damn*-foolproof! ■

Power Plus for the Omni

—improving on Ten-Tec's power supply

The Ten-Tec Omni (#252-MO) power supply is a fine unit, but there are some improvements that can be made. I am sure competition dictates just how much a manufacturer can put into a piece of equipment, but there is no reason ham operators cannot make a few usable modifications themselves. The modifications I made were relatively simple, and I now have a better and more useful power supply.

My first modification was to install a chassis-mounted ac receptacle to be powered whenever the power switch is turned on. This provides a switched source for a cooling fan. By doing this, my cooling fan is on any time that my power supply is on and I cannot forget to turn it on (see Fig. 1).

My next undertaking was to install an overvoltage protection (crowbar) circuit. This is a must to protect expensive gear from being zapped should a pass transistor become shorted and allow excessive high voltage to reach places it should not! The crowbar circuit described in the August issue of *73 Magazine* (page 90) by K9MLD was used. (See Fig. 2). All of the components were mounted on a three-lug terminal strip with the exception of the 25-Amp SCR, which was mounted on a bracket of its own. Space is no problem. I used a 2N685 SCR which must be isolated from ground, as the stud is the positive terminal. Fuse installation is very simple. With a fuse holder mounted on the back cover of the power supply near the top edge, the red wire from the pass transistor can be cut near the center and connected to the fuse holder without disconnecting either end of the wire.

With this circuit connected to the 13.8 positive voltage line, should the SCR be gated by an overvoltage signal, the SCR will short the 13.8 positive voltage line to ground and blow the fuse, thereby positively disconnecting the output of the power supply. Should you have a variable power source available, the trimpot can be adjusted to gate the SCR at 15 V and marked at that position. After installation in the power supply, the trimpot can be turned to test for proper operation, and when testing is completed, returned to the marked (15-V) position. During checkout, the current limiter (not the fuse) was shutting down the power supply inadvertently. This apparently was being caused by rf getting on the gate of the SCR, causing the SCR to conduct. The installation of the two .01 caps corrected this problem (see Fig. 2).

There was no reason to have two 12-volt power supplies in my shack (one for my Omni and the other for other equipment such as the 2m rig), so I set out to eliminate the home-brew job and use the Ten-Tec #252MO for everything.

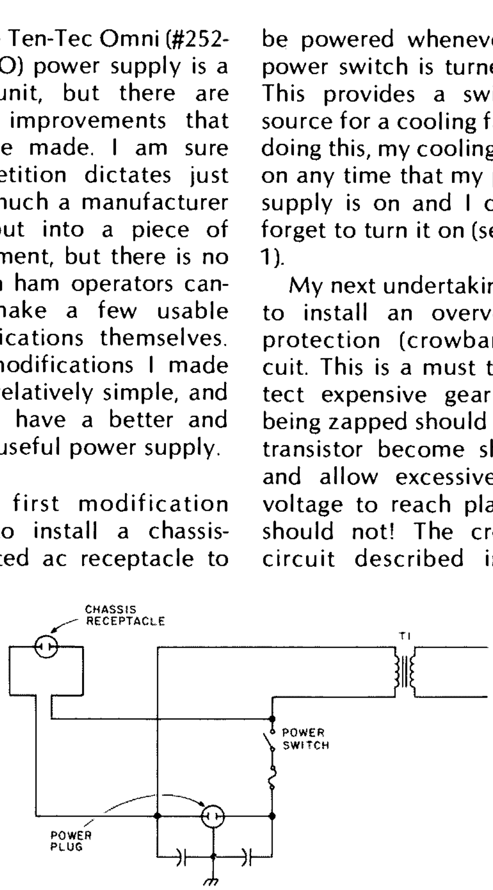

Fig. 1.

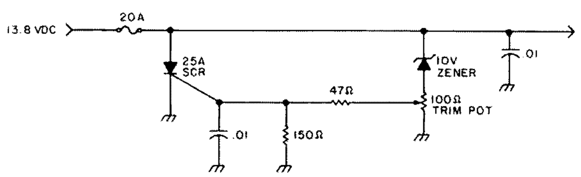

Fig. 2.

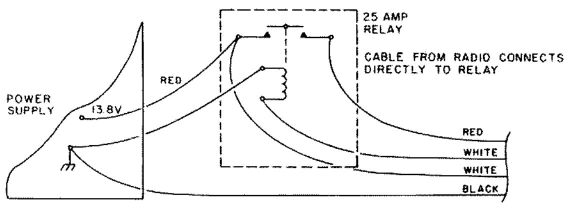

Fig. 3.

The manufacturer designed it to be turned on by the power switch on the Omni in series with the on/off switch on the front of the power supply. The power supply could not be turned on and used without the Omni being turned on as well. A simple rearrangement of the 115-V ac wiring in the power supply bypassed the switch on the radio and allowed the power supply to be turned on by the switch on the power supply only (see Fig. 1).

To control the 13.8 V dc to the Omni, a 25-Amp Potter & Brumfield #PR5DY relay was installed, as suggested in the owner's manual. The relay coil is controlled by the switch on the Omni through the two center wires of the cable between the power supply and the radio. Now my Ten-Tec power supply can be turned on without turning the Omni on (see Fig. 3).

Note: To facilitate mounting the relay, the two auxiliary phono jacks and their associated wiring were removed and discarded, and two banana plug type jacks were installed in the front panel, with wiring capable of handling the total output of the power supply. This makes 13.8 V dc readily available for anything in the shack with current limiting and overvoltage protection.

So, Ten-Tec owners, if you are of the mind to do a little improving of your equipment, the details are left to your discretion, imagination, and ingenuity. I might add that the #252M and #252MO are identical electrically, so these modifications apply to both. The peace of mind that comes from having the overvoltage protection is reward enough, not to mention the good feeling of knowing that I did it myself! 73. ■

Oddball Offsets for the KDK-2015R

—make a good rig better

Did you ever wish you could program any offset into the 2015R? If so, read on. Here is a cheap ($0-$5, depending on your junk box) modification which will do just that, without drilling any holes or installing any extra switches. The KDK has all you need and even has the correct labels on one of the switches. The offset frequency can be programmed into the memory in the normal manner, and the KDK will display transmit and receive frequencies when the PTT switch is operated. It does not interfere with the normal function of the memory scanner, either.

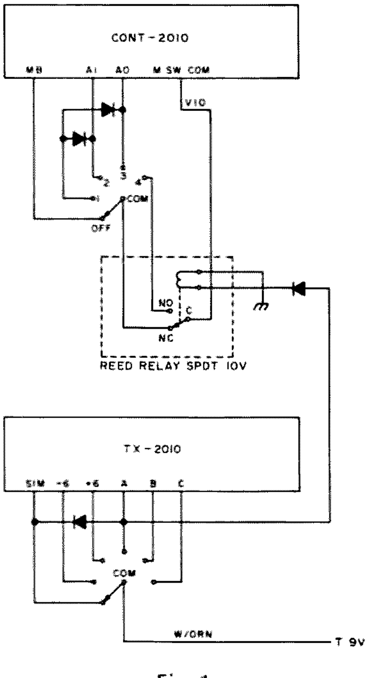

Fig. 1.

All of the tools that are needed to do the job are a small soldering iron, a Phillips screwdriver, dikes, and perhaps a pair of tweezers or hemostats. The only materials needed are an SPDT reed relay with a 10-V coil, two diodes, some hookup wire, and solder.

Study the diagram (Fig. 1) so that you will understand the hookup and proceed as follows:

1. Remove the four screws from the case and remove both halves.

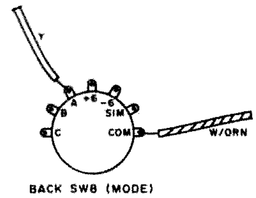

Fig. 2.

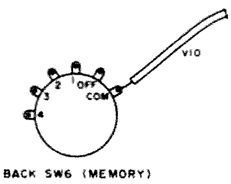

Fig. 3.

2. Turn the rig on its back with the antenna connection facing you.

3. Locate SW8 (Fig. 2) and lift the yellow wire from tab "A". Insulate the end with spaghetti.

4. Solder a diode between the tab marked "A" and the tab marked "SIM"; observe polarity.

5. Solder a piece of hookup wire to the tab marked "A". The length of the hookup wires will depend on the make of switch you use and where you locate it. This is all of the work to be done on SW8.

6. Locate SW6 (Fig. 3) and lift the violet wire from the tab marked "COM".

7. Solder a piece of hookup wire to the violet wire and cover the splice with spaghetti.

8. Solder a piece of hookup wire to the tab marked "4". This is a tight place; be careful not to melt any wires.

9. Select the place to install the reed relay. I put mine on the rear side of the CONT-2010 board on the

left-hand end in front of L6 and L7 on the PLL-2010 board, with the connections pointing up. It can be fixed in place with Silastic™.

10. Place a solder lug under the front-left corner screw on the PLL-2010 board.

11. Solder a piece of hookup wire to the solder lug.

12. Solder the other end of this wire to one side of the relay coil.

13. Solder a diode to the other end of the relay coil. Observe polarity.

14. Solder a wire from SW8, tab "A" (step 5) to this diode.

15. Solder the extension of the violet wire (step 7) to the common terminal of the relay.

16. Solder a piece of hookup wire to SW6, tab "COM" (step 6) and solder the other end to the NC contact of the relay.

17. Solder the wire from SW6, tab 4 (step 8) to the NO contact of the relay. This completes the modification. Be sure that none of the connections will touch the case. Check your wiring and install the case halves.

To operate, program the transmit frequency into the number 4 memory in the normal manner. Set the receive frequency on the vfo. Place the mode switch in the "A" position. Place the memory switch in the OFF position.

Now for the moment of truth. Press the mike button and, presto, the transmit frequency programmed into the number 4 memory is displayed. Release the button and the receive frequency in the vfo is displayed.

This modification works well, costs about the same as one offset crystal, takes about an hour of your time, and is fairly easy to do. Have fun! ■

Grove Enterprises, Inc.
Rt. 1, Box 156
Brasstown NC 28902

It was a foggy Monday, August 13, 1979, when Walter Hann OE8WHK switched on his Bearcat 101 scanner. Immediately, the scanner locked onto a local police channel and Hann learned of a frantic rescue attempt being conducted in the picturesque Austrian Alps a few miles from his home.

But the communications was by no means routine. A local ham radio operator, OE8PPK, was unwittingly causing interference on a nearby amateur frequency, preventing the police from making radio contact with the rescue helicopter hovering nearby, desperately searching for the injured victim.

Walter Hann grabbed the microphone of his two-meter Icom IC-215 and immediately called OE8PPK to urge him to QRT so that the rescue mission could proceed. The other ham dutifully complied, thanking Hann over the air for alerting him.

This initial episode was the very essence of amateur radio at its best: A ham radio operator, aware of a life-saving attempt being threatened by a communications problem, takes immediate action to solve the interference problem. Unfortunately, the story did not end there, for in Austria it is illegal to possess a radio capable of monitoring police calls.

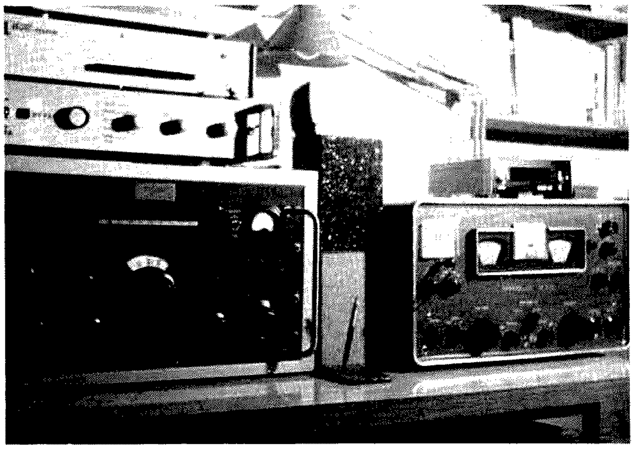
The interfering transmissions of OE8PPK had been tape-recorded by the police for follow-up, and now they heard Walter Hann's name and callsign being announced by the involuntary intruder.

Because Hann is an employee of the Austrian government, identification came quickly. Officials rapidly made the 20-km journey from Klagenfurt to St. Veit/Glan, Hann's QTH, and there confronted his wife.

Although Hann was no longer at home, the PTT officials demanded access to the ham shack where they siezed the Bearcat and made note of all other equipment owned by Hann.

The next day Hann was summoned to Klagenfurt for a three-hour interrogation. His inquisitors wanted to know where he got the equipment, how it cleared customs, who else had such equipment, and other details about his monitoring hobby.

Since Hann is employed by the government, he was dealt with harshly. He was forced to forfeit the Bearcat receiver and pay a steep



A small segment of Walter Hann's listening post.

fine. But that wasn't all. In November, two Customs investigators came to his office and conducted a lengthy hearing. How did the BC-101 get into Austria? How much did he pay? Who else owns similar equipment? How was his ham equipment brought into the country?

Hann owned a Drake R-4B, an SPR-4, and an FS-4 synthesizer, a Barlow-Wadley SCR-30, a HAL RVD-1002 RTTY demodulator, a Collins 51J3 receiver, and many other pieces of gear. The officious officials pointed out that unless Hann could produce legal proof of customs clearance, they would conclude that all the equipment had been smuggled into Austria.

Since Customs officials could not determine that Hann had used the equipment in the commission of an illegal act, he was not imprisoned. But he has been assessed heavy fees for additional duties, fined for the act of listening to a private communication, and is now awaiting additional disciplinary action because of his government position with the Austrian Finance Administration (Customs). This action will probably be both verbal and punitive, and Hann expects his salary to be cut.

Investigators then intruded into Hann's private papers, looking for evidence of illegal activities, confiscating a letter from an American collegue who offered to send him a Bearcat 250 scanner.

In the United States, any citizen is permitted by law (Section 605, 1934 Communications Act) to monitor for his own personal interest any radio communication of any nature, just as long as he does not disclose the contents to another person or use the information for his own personal gain.

Zustellung zu eigenen Handen

(Behörde)

GZ. 24915-3/79 Klagenfurt, am 29. August 1979

An Herrn Walter HANN, Finanzbeamter,

Neubaugasse 23

9300 St.Veit a.d.Glan

Beschuldigten-Ladungsbescheid

Es wird Ihnen zur Last gelegt, in der Zeit von 2. Juni 1979 bis 13. August 1979 in St.Veit an der Glan eine Funkempfangsanlage, welche zum Empfang von nicht für die Allgemeinheit bestimmten Aussendungen geeignet ist, ohne fernmeldebehördliche Bewilligung verwahrt, errichtet und betrieben

und dadurch ~~eine~~ Verwaltungsübertretungen nach § 26 des Fernmeldegesetzes, BGBl. Nr. 170/1949, begangen zu haben.

Gemäß § 40 Abs. 2 und § 41 des Verwaltungsstrafgesetzes werden Sie aufgefordert, unter Mitnahme dieses Ladungsbescheides und

zur Vernehmung — mündlichen Verhandlung —

am Mittwoch, den 12.9. 1979, 9.00 Uhr

bei diesem Amte, II. Stock, Zimmer Nr. 132

~~beim Amtstag in~~ persönlich zu erscheinen oder einen mit der Sachlage vertrauten und schriftlich bevollmächtigten eigenberechtigten Vertreter zu entsenden. Die Vollmacht ist stempelpflichtig.

Gleichzeitig werden Sie aufgefordert, die Ihrer Verteidigung dienlichen Beweismittel mitzubringen ~~oder~~ diesem Amte so zeitlich anzuzeigen, daß sie zur Vernehmung herbeigeschafft werden können.

Im Falle ungerechtfertigten Ausbleibens

wird gemäß § 41 Abs. 3 des Verwaltungsstrafgesetzes das Strafverfahren ohne Ihre Anhörung durchgeführt werden.

~~haben Sie gemäß § 19 Abs. 3 des Allgemeinen Verwaltungsverfahrensgesetzes Ihre zwangsweise Vorführung zu gewärtigen.~~

Gegen diesen Bescheid ist zufolge § 19 Abs. 4 des Allgemeinen Verwaltungsverfahrensgesetzes kein Rechtsmittel zulässig.

Für den Präsidenten:

Official summons served by the Austrian PTT.

But an unsettling spectre has appeared on the horizon. A number of new interpretations, prospective amendments, and even an entire rewrite of the Communications Act threaten to undermine the American privilege of listening in.

The catalyst for these actions has been the common-carrier television industry, disturbed because of the prospect of home TV viewers picking up satellite programs direct without having to pay subscriber fees. Law enforcement agencies are also concerned about the use of scanners to evade apprehension. Several bills are now on the floor of Congress intended to limit our constitutional right to listen.

Will it be the conscientious amateur community who will protest the implementation of these restrictions on our rights? Only you can answer that question. ■

Put "the Rep" in Your Repeater

—an automatic autopatch dialer

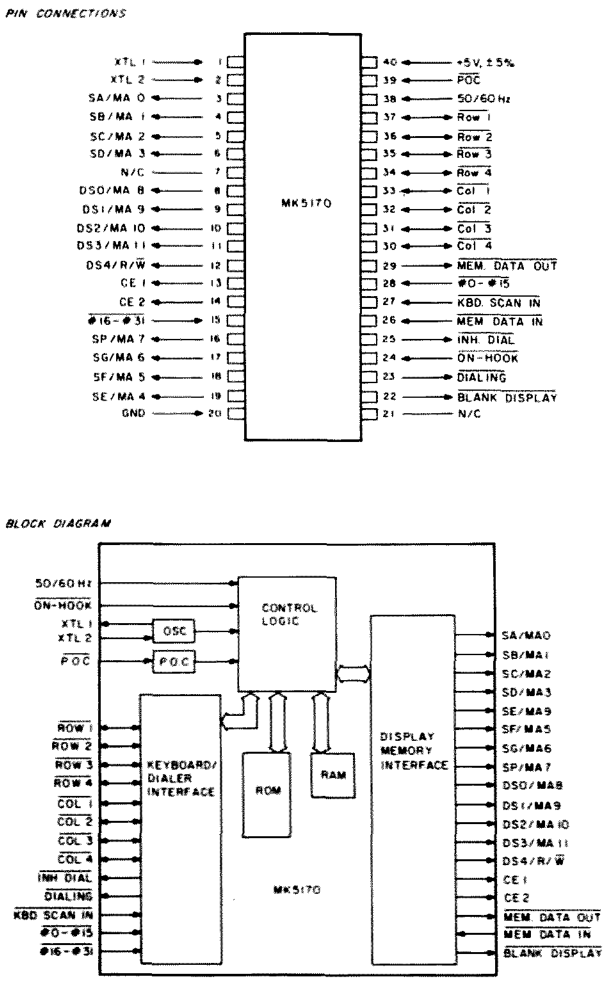

Fig. 1. Pin connections and block diagram.

O.C. Stafford K4ALS
3702 Holts Chapel Rd.
Greensboro NC 27401

Continuing changes and interpretations of FCC rules indicate that autopatch facilities attached to amateur repeater stations must be monitored to prevent the abuse of the autopatch.

Because of these requirements and other restrictions, numbers of clubs have discontinued the use of their autopatch facilities or else now have a very limited operation. Some clubs have disintegrated over the issue of autopatches. One solution, however, is to use a control operator to monitor the calls.

One of the big problems facing owners of repeaters equipped with autopatch is the ability to control the numbers being dialed. Another problem is that some people make calls which are not really legal or are not in the best interests of ham radio. Now you can control what gets dialed, with the Rep.

The circuit described in this article makes use of the repertory dialer chip, the MK5170, made by Mostek. The chip is a 3870 microcomputer that has been programmed to act as a repertory dialer. The pin connections diagram is shown in Fig. 1. The unit can be programmed with only approved phone numbers for later dialing.

The chip can be addressed by a touchtone™ pad in a minimum-hardware configuration. It will store up to 100 phone numbers which can be loaded and retrieved with a two-digit access code. The circuit diagram for the 100-number system is shown in Fig. 2. If a system with 24 numbers or fewer is needed, the memory circuit of Fig. 3 can be used.

I have tried to include enough hardware and logic on the board to make the circuit easier to interface with systems other than the Buffington phone patch and control system which has been described in past issues of *73 Magazine*.[2] That system will be used to show how the unit can be interfaced.

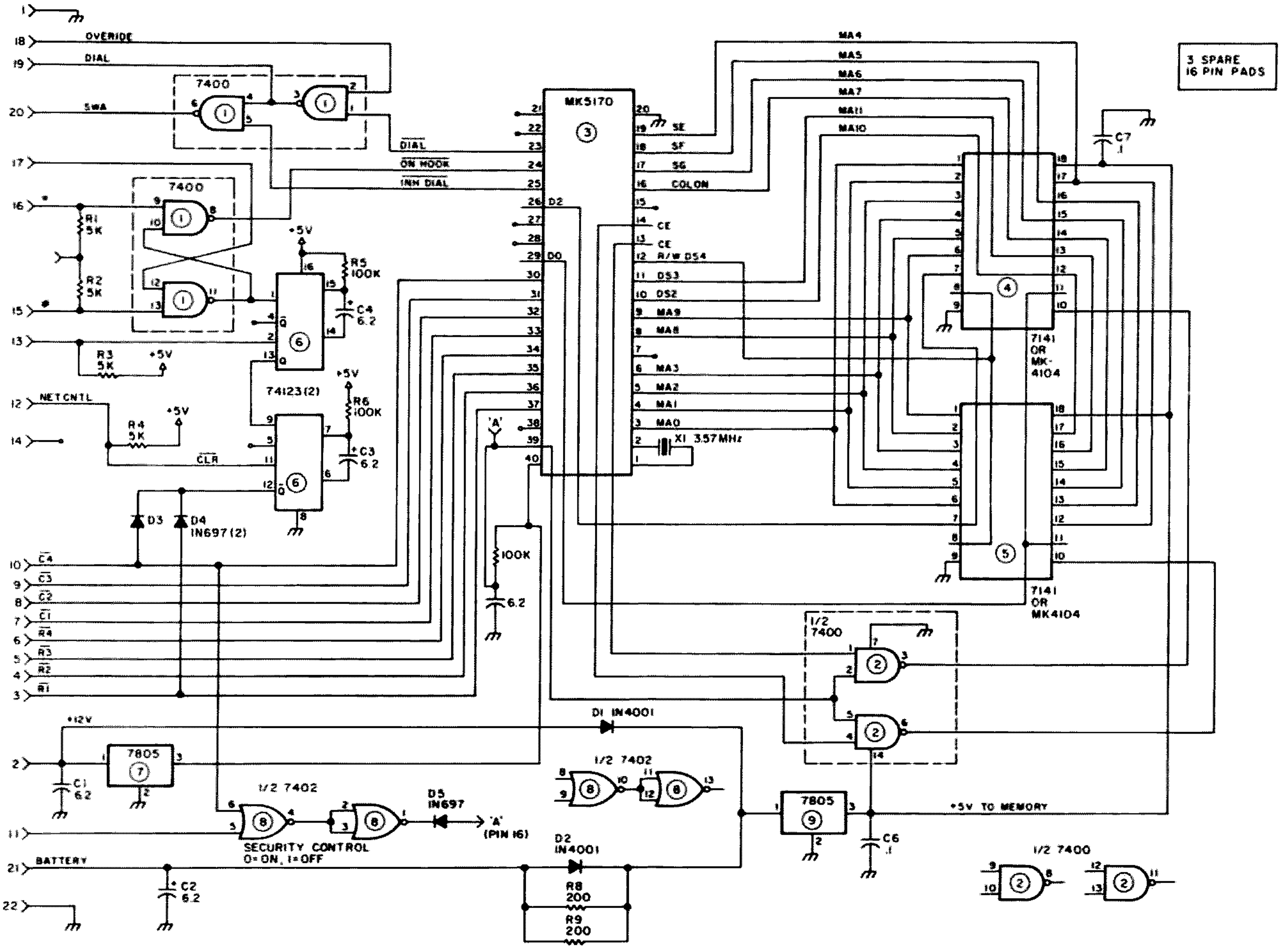

Fig. 2. Circuit diagram for the 100-number system.

There are three control pins which define the mode of operation: Pin 23 indicates that a dialing cycle is in progress by going low, pin 24 (if low) indicates that the phone is on hook, and pin 25 goes low during data entry and is used to inhibit the dialer circuit.

Fig. 4 shows how the unit is connected to the autopatch and control system described by Buffington. The unit operates in the Dial mode when accessed by a user and in the Enter mode when accessed by a control station. Fig. 5 shows the actual hardware hookup. Fig. 6 shows the switch circuit that is used to route data between the decoder, the dialer, and the Rep.

To access the Rep, the user must use the following sequence:

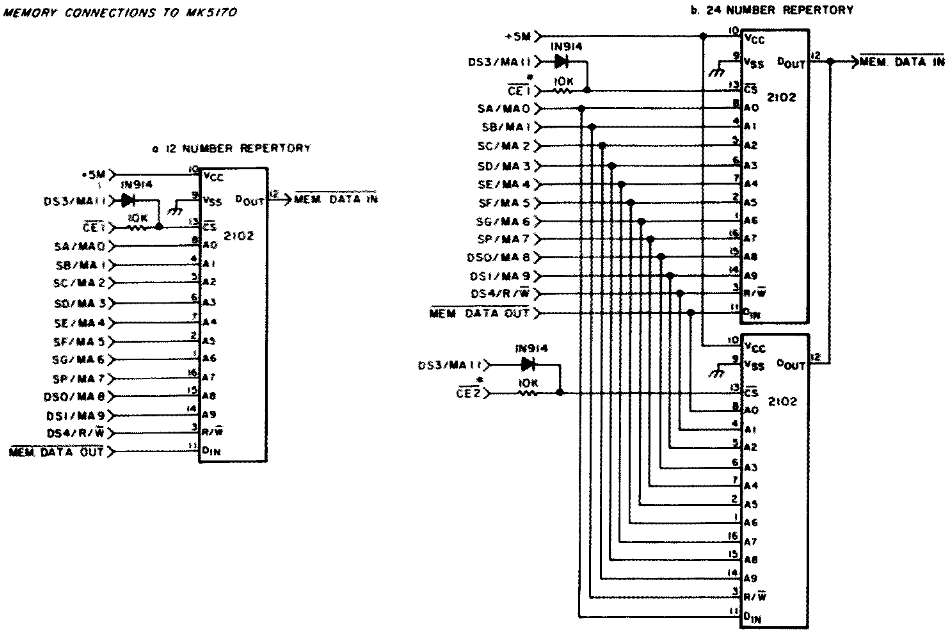

Fig. 3. Memory circuit for a 24-number (or fewer) system. It can be built on header chip and attached to the 18-pin socket.

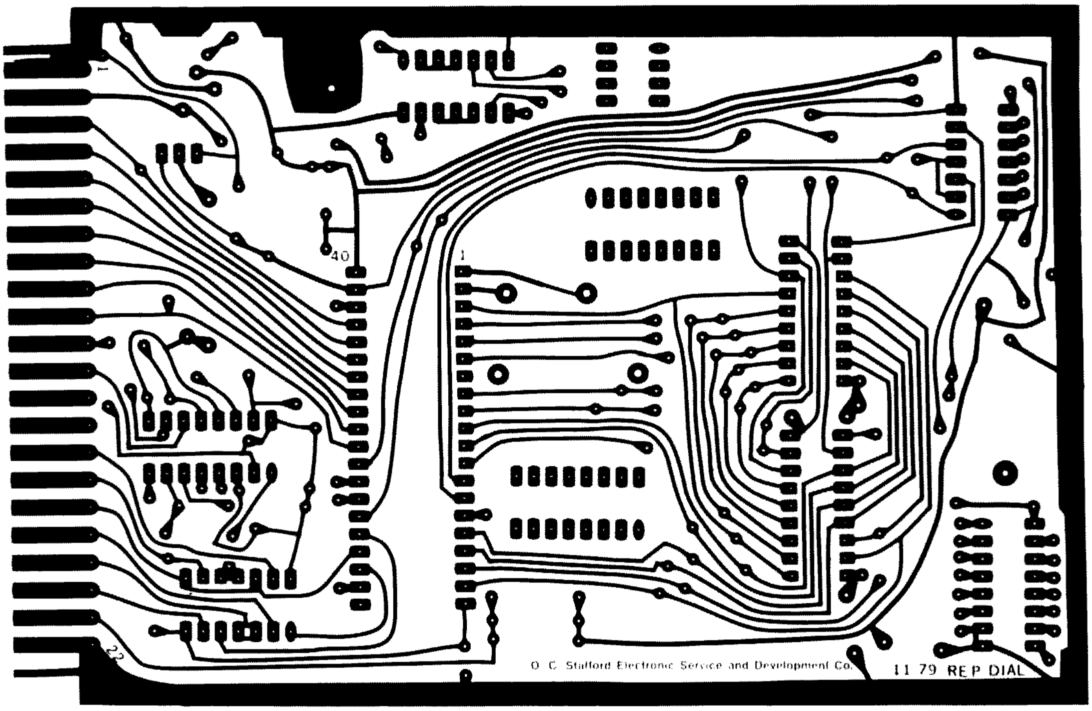
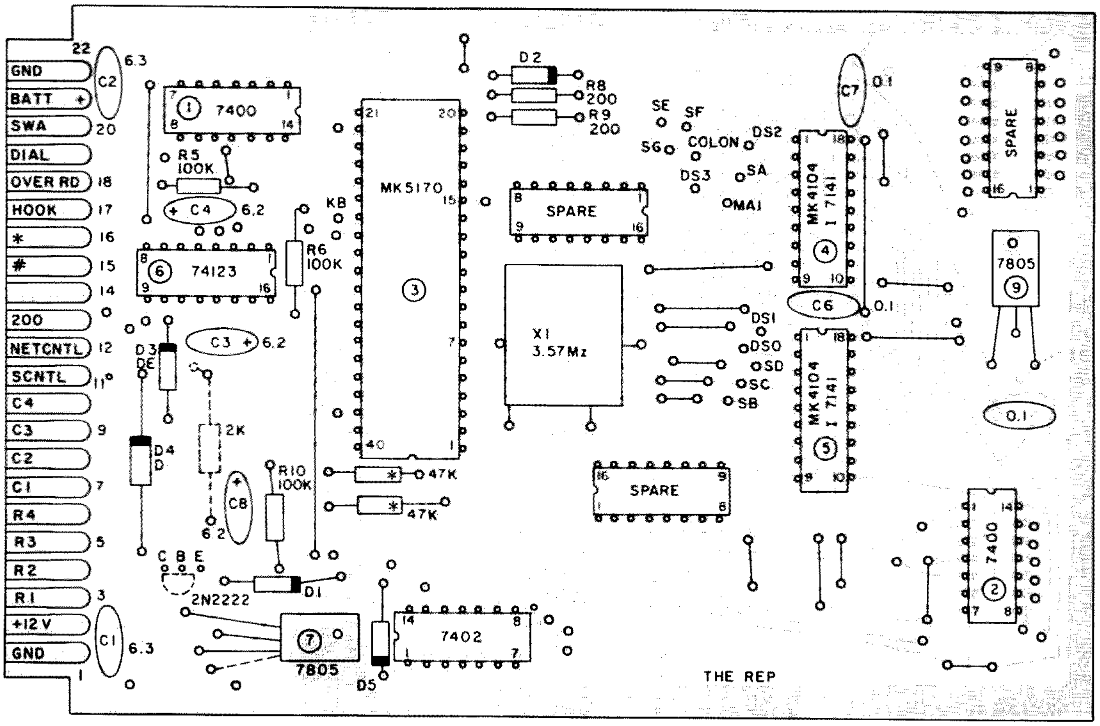


PC board for the repertory dialer.



Component layout for repertory dialer.

1. Identify and state your intention to make a call. (This is good operating procedure any way you look at it.)

2. Enter *. This causes the demux circuit to lock out for 20 seconds, connects the dialer to the phone line, starts the three-minute timer, and readies the Rep to look for two numeric digits.

3. Wait for the dial tone, then enter the two digits.

4. The phone number associated with the two digits will be retrieved, and pin 20 will go low while pin 12 goes high, causing the decoder circuit to disconnect and the dialer to be connected to the Rep. The number is then transmitted to the dialer from the Rep. It takes 980 milliseconds for a seven-digit number to be transferred to the dialer with a 3.57-MHz clock.

5. Once the call is completed, send # to knock the patch down and reset the Rep.

The system has some built-in security. A 4×4 touchtone pad is used to access the unit for loading. The pad is shown in Fig. 7. The security function will not allow the user to get into the Enter mode when the phone is off hook. The Enter is sent when the security lock is on; the Rep simply resets. The lock and unlock sequence code should be known only to the control station, and is controlled by the demux/sequence circuit.

The demux and sequence boards are needed if the phone numbers are to be loaded from a remote location, as shown in Fig. 5.

The control station uses the sequence circuit to unlock the system for programming. Programming is accomplished using the following sequence:

1. The control station generates a # to make sure the phone is on hook.

2. Send a sequence code to latch pin 12 low and pin 11 high in order to lock out the security function.

3. Press the Enter button.

4. Key in two numeric digits for the address code of the phone number.

5. Press the Clear key to clear the area where the number will be loaded.

6. Key in the phone number.

7. Press the Store key.

8. If more numbers are to be loaded, go to step 5, or unlatch pins 12 and 11. Provision for battery back-up is provided on the board. A 9-volt nicad should be used with this circuit. When the main power fails, the chip enable lines go high. This causes a drop in current to the chip. The trickle charge circuit will not allow the nicads to overcharge.

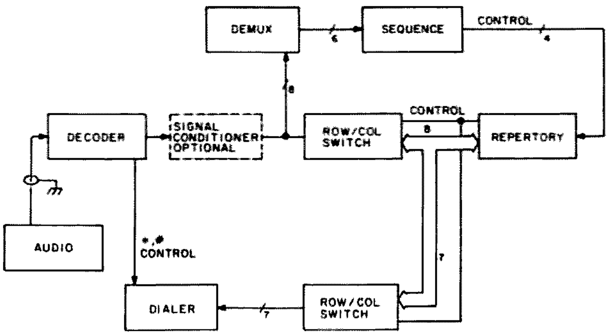


Fig. 4. Repertory connection to phone patch.

The override circuit is used to defeat the Rep and connect the decoder to the dialer for manual dialing. The control station, through a sequencer, makes pins 18 and 12 go low. The patch is brought up with *, and after the dial tone is heard, the dialing can start.

System security is achieved by locking out any column 4 signal by grounding pin 11 using a sequence circuit. If a column 4 signal is received, the Rep goes off hook and the next two digits simply cause the circuit to get a number, but not dial it, since the patch is not on and the unit is in the dial mode, so no damage can be done.

Most repeater groups

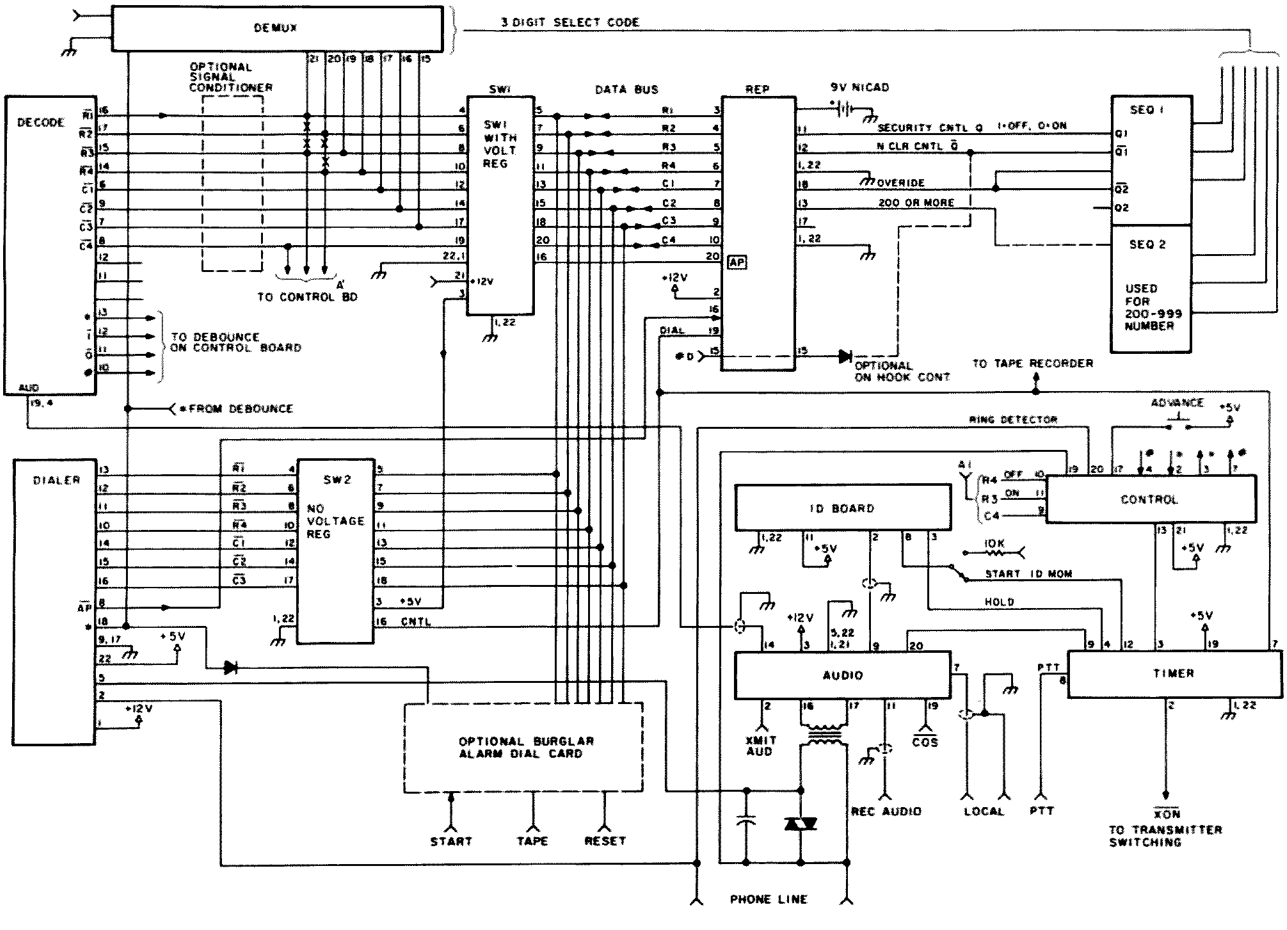

Fig. 5. Basic repeater control system with repertory dialer.

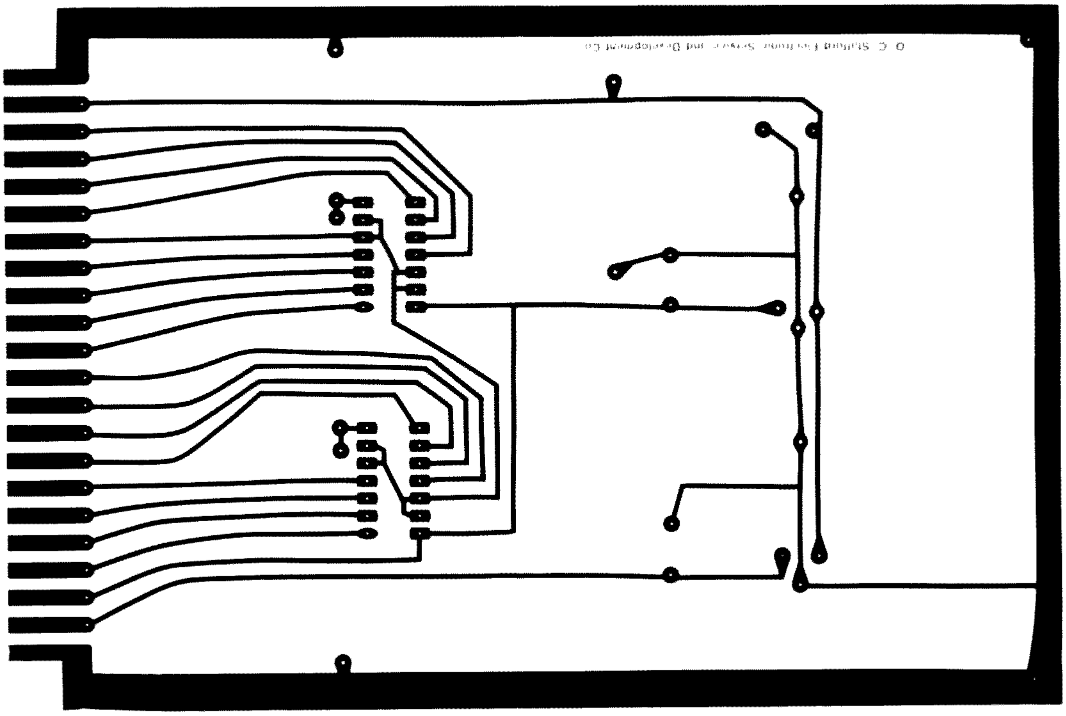
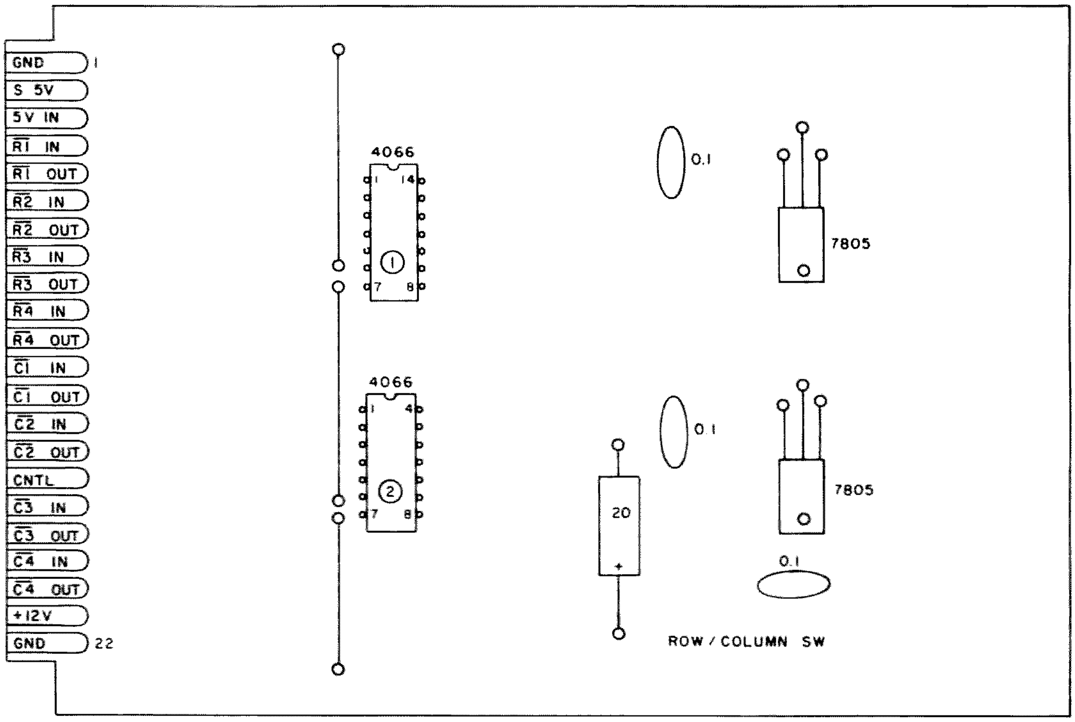


PC board for the row/column switch and regulator.



Component layout for the row/column switch and regulator board.

have fewer than 100 members. One use of the Rep could be to direct calls to speci^l numbers for assistance. For example: If the first two digits of all the exchanges in your area are used as access codes to a common number, then that number would be reached whenever the patch is accessed. This could be helpful if a visitor tries to access the patch with a regular phone number but no access code.

What if your group has more than 100 members and everybody needs a number? No problem. The system can be expanded to select additional 100-number banks. The expansion circuit for a 200-number system is shown in Fig. 8.

To go above 100 numbers requires adding a bank-select digit. The delay gen-

Parts List

Row/Column Switch Board

Quad switches, 4066	2
Voltage regulator, 7805	1
Capacitor, 0.1-uF, tantalum	1
Card edge connector, 22-pin	1
14-pin IC socket	2

Printed circuit board: drilled $7.50, undrilled $5.80.

Rep Board

Capacitor, 6.2-uF, tantalum	5
Capacitor, 0.1-uF, tantalum	2
Resistor, 100k, 1/4 W	3
Resistor, 5.1k, 1/4 W	4
Resistor, 200k, 1/4 W	2
Voltage regulator, 7805	2
Diode, 1N4001	2
Diode, 1N697	3
Crystal, 3.57 MHz	1
Dialer, MK5170	1
Dual one-shot, 74123	1
Quad NAND gate, 7400	2
Quad NOR gate, 7402	2
RAM memory, MK4104	2
16-pin IC socket	1
14-pin IC socket	3
18-pin IC socket	2
40-pin IC socket	1
Card edge connector, 22-pin	1

The above items make up the parts kit, for $100.00. Printed circuit board: $12.50 drilled, $9.50 undrilled. Parts and boards are available from O.C. Stafford Electronic S and D Co., 427 South Benbow Road, Greensboro NC 27401, phone: (919)-274-9917.

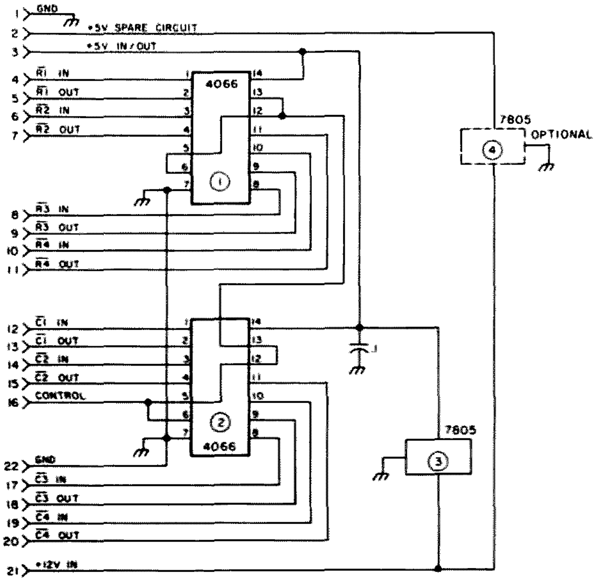


Fig. 6. Row/column switch and regulator board.

erated by the first section of IC6 is increased to 5 seconds. During this five-second interval, the bank-select digit is keyed right after the * and before the five seconds have elapsed.

The input to the row/column lines on the Rep board is not effective during this time because the MK5170 is held in a reset condition and the bank-select switch is on, allowing the digit to be decoded and clock one of the flip-flops. When the call is completed, the bank

BASIC SYSTEM KEYBOARD CONFIGURATION

Fig. 7. Touchtone pad.

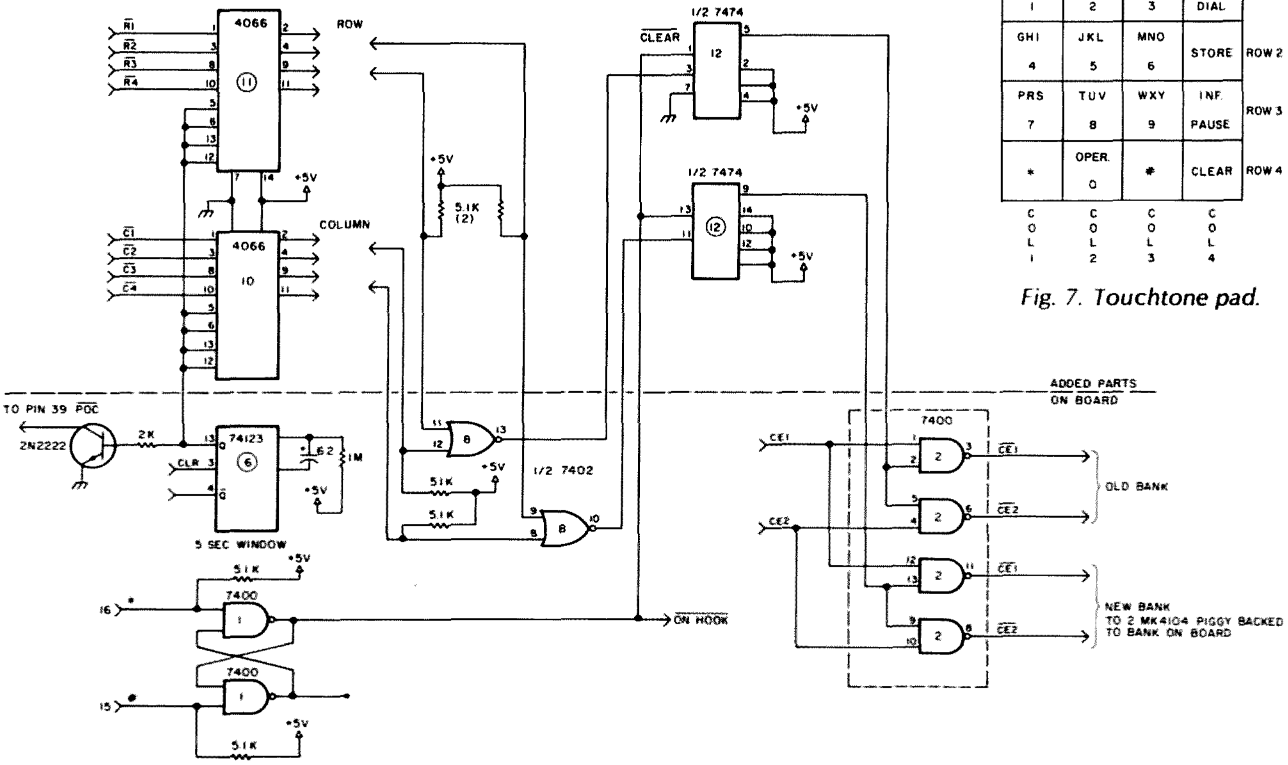

Fig. 8. Expansion circuit for a 200-number system.

flip-flops are reset through diode D6.

In loading a number, the control station pulses pin 13 to get the 5-second window for the bank select. The procedure for loading a number is then used to complete the process.

The spare IC pads on the circuit card can be used to add the 200-number system. The extra memory chips are piggybacked onto the existing chips with chip enables connected to the appropriate bank-select pins. I suggest you use wire-wrap techniques to build the addition, if you need it. Using this type of logic, the circuit can be expanded to handle 999 numbers! If you need that many, you will have to buffer the address lines and add a memory board.

The original control system used R1, R2, and C4 to control the transmitter. This function should be changed to a sequence circuit. The R1/C4 combination could cause the Rep to go into the Enter data mode.

R3 and R4 can be used in place of R1 and R2 and the operation of the Rep will not be affected.

It is hoped that the ideas presented in this circuit will help to alleviate some of the problems associated with autopatches. At the least, it can reduce the hazard of dialing while driving.

I will appreciate any and all comments on this circuit. If you have any questions about how the circuit operates and would like answers, send me a letter along with a self-addressed, stamped envelope. ■

Quick and Dirty Line Noise Suppressor

Robert B. Grove WA4PYQ
Rt. 1, Box 156
Brasstown NC 28902

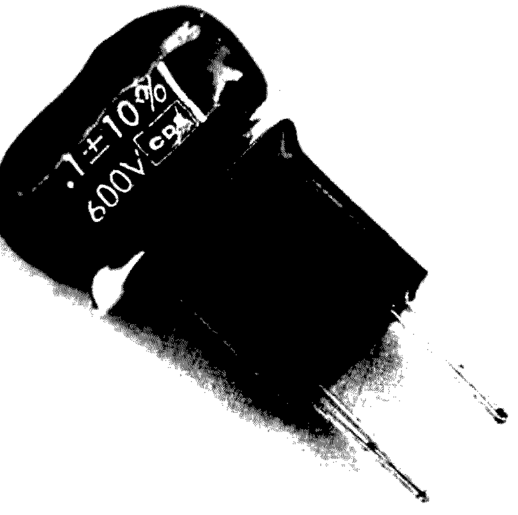

Photo A.

One of the most irritating sources of electrical noise, characterized by sharp clicks heard through the speaker of a receiver, is contact noise. The make/break cycles of appliances, aquarium heaters, flashing Christmas tree lights, and other noisy electrical contacts can wreak havoc with radio reception.

Fortunately, there are several options which may be elected to minimize these ear-splitting distractions. Perhaps the simplest is the installation of a 0.1-uF capacitor across the contacts themselves.

Since it is often difficult to find direct access to the offending contacts, an alternate solution is found by bypassing the plug with the capacitor. Probably the simplest way to do this is by rigging a plug-in interference filter as shown in the photo.

For standard 120 lines, select a mylar™ capacitor with a 600-volt rating. Insulate the exposed capacitor leads and connect them directly to the terminal screws of any convenient plug. Insert the plug-in filter into the same outlet as used to power the offending contact device.

The bypass capacitor acts as a smoothing filter for the sharp voltage-spike transients generated by the sparking contact. While it is true that the capacitor might actually resonate an unusually long line cord to enhance the noise at some frequency, in actual practice this is extremely unlikely to happen within the passband of most receiving installations. ■

Over the Hump and into History

—the last flight of #42-107270

November 30, 1943: In a C-87 airplane (number 42-107270) somewhere over the Himalaya Mountains of Asia, radio operator Kenneth Spencer, a 19-year-old corporal from Rockville Center, Long Island, anxiously twisted the dials of his HF command sets, trying to raise one of the ground stations he knew should be down below.

In the cockpit, Lt. Robert Crozier of Waco, Texas, the pilot, and Flight Officer Harold McCallum of Quincy, Massachusetts, the copilot, sat straining their eyes in an attempt to see anything other than the black storm clouds at 24,000 feet.

Aft of the radio shack, Sergeant William Perram of Tulsa, Oklahoma, kept a sharp eye on his dwindling fuel supplies, while the fifth man in the plane, PFC John Huffman of Straughn, Indiana, wondered what was happening.

Though listed on the manifest as assistant engineer, Huffman didn't belong in the plane. Three days earlier, he'd made his first flight east over the Hump from Jorhat Airbase in the Assam Valley of northeast India, to Kunming, an American base 550 miles away in China. At Kunming, he'd been grounded because of a head cold and was deadheading home. He was on the manifest in order to draw special flight pay. Huffman had no access to the inter-crew phone system and relied on shouted explanations of what was happening.

What was happening was that they couldn't find their way back to Jorhat.

Earlier in the day, the C-87 (which was a modification of the B-24 bomber known as the *Liberator*, built by consolidated Aircraft Corporation of San Diego and identical to the B-24 except for the removal of machine guns, turrets, bomb-handling equipment, and related controls, and the addition of a floor in the cargo compartment and a row of windows on either side of the fuselage), had made a quiet flight from Jorhat to Kunming carrying a load of 55-gallon drums of fuel destined to be used by bombers and fighters striking at the Japanese further east and south in China and Burma. They had dropped the fuel at Kunming and been given a partial load of garden produce to go to Yunannyi, about 45 minutes west of Kunming and almost directly on the western flight plan. They had left Yunannyi at about 6 pm, anticipating a routine flight back to Jorhat.

But no flight over the Hump was ever truly routine. By the end of the war, more than 400 planes and 850 men were lost flying the 50-mile-wide corridor, which became known as Aluminum Valley because of the wrecked planes littering the mountain slopes. In clear weather, pilots navigated from one collection of wreckage to the next. In November and December, 1943, there were 38 and 28 *major* accidents, respectively, over the Hump. Between June and December 1943, 168 men were killed making the trip. Some were shot down by marauding Japanese Zeroes up out of Burma, while others were killed when their planes flew into a mountain during the unpredictable storms which sometimes had winds measured at 200 mph. Despite weather as severe as any in the world, the planes flew 24 hours a day, stopping only to change crews, load and refuel, and receive required maintenance.

In September, 1943, Colonel Thomas Hardin was given command of Hump operations; one of his first orders was that "Effective immediately, there will be no weather over the Hump." In the face of extreme icing conditions, high winds, zero visibility, and attacks by Japanese planes, the crews and their aircraft kept flying.

Although the C-87 had a range of about 3000 miles and a ceiling of about 30,000 feet with its four Pratt & Whitney 1200 horsepower engines, it was often hampered by maintenance problems. Parts came from the US via the longest supply route in military history. Temperature ranges from 100 plus degrees at sea level in the Assam Valley to below zero at altitude, coupled with high humidity on the ground, caused rapid rusting and breakdown. The communications equipment was as susceptible to trouble as any other part of the aircraft, and the HF gear was often affected by severe electrical storms over the Hump, caused when warm air from the Bay of Bengal met cold air sweep-

ing down across the steppes of north central Asia.

The plane was equipped with up-to-date specialized navigational gear, but some of it was useless because no Hump base had the counterpart equipment.

The C-87 had the same radio gear as its parent B-24, except that the C-87 had fewer interphone crew stations due to elimination of the bombardier and gunner stations on the plane. If the interphone was operating correctly, all crew stations could hear the radio compass signal, the liaison and command radios, and other crewmen.

The command radio equipment in 1943 was high-frequency type (in 1944 upgraded to UHF) and, according to the B-24 manual, was used for plane-to-plane communications, though in practice it was used for all normal traffic, air-to-air or air-to-ground, because all crew members could either receive or transmit via the command set. The command gear included two transmitters mounted on racks on the deck over the wing, along with three receivers. A modulator unit, an antenna-switching relay, a transmitter-control box, a receiver-control unit, a dynamotor, a terminal strip, and two receiver dynamotors completed the rig. The command radio, like most other equipment on the plane, operated on 24 V dc.

The two transmitters had frequency ranges between 5300-7000 kilocycles (kc) and 7000-9100 kc. The three receivers covered frequencies of 190-550 kc, 3000-6000 kc, and 6000-9100 kc.

The liaison equipment was of medium power. Its transmitter had seven removable tuning units supplied with it. The tuners could be inserted by the operator to change frequencies in flight. The tuners handled 200-500 kc, 1500-3000 kc, 3000-4500 kc, 4500-6200 kc, 6200-7700 kc, 7700-10,000 kc, and 10,000-12,500 kc. An antenna-tuning unit, a frequency meter, a receiver in frequency range from 1500-18,000 kc, a dynamotor, a transmitting key, an antenna-transfer switch, and a 200-foot trailing antenna made up the liaison unit. (According to the B-24 manual, the liaison radio could be controlled by the radio operator, pilot, or copilot. Harold McCallum, copilot of #42-107270, says the C-87 liaison gear could be controlled only by the radio operator and was not normally used because of this limitation.)

The radio compass was a 15-tube superheterodyne receiver using 24-28 V dc for operation of the relays. The radio circuits ran on 110 volts ac at 400 cycles; the 110 juice was supplied by inverters under the flight deck, which also supplied power for autosyn instruments and the interior lighting. The loop was electrically driven and could be controlled from either of two remote boxes.

Marker beacon equipment operated on ultra-high-frequency signals at 75 megacycles (mc) and could receive signals from instrument landing systems (ILS), fan stations, cone-of-silence stations, and any other station equipped with horizontally-polarized 75-mc wave systems. According to McCallum, there were no ILS systems in the China-Burma-India (CBI) Theatre, although Chabua had a cone-of-silence system. Planes entering the range received either A or N signals in Morse code, depending on their relation to the range. On the correct approach, no signal was received.

There were six antennas on the B-24/C-87. The command antenna was a single wire from the top of the fuselage above the wing to

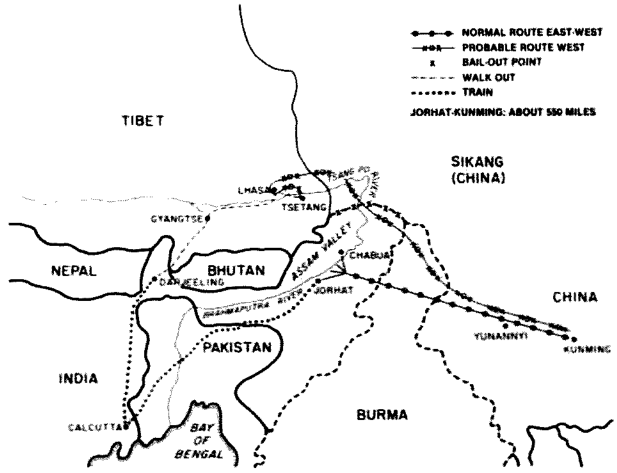

Fig. 1. Map of the area.

the top of the left vertical stabilizer (the B-24/C-87 had a twin-tail unit), while the liaison fixed-antenna wire ran to the right vertical stabilizer. The radio compass had two antennas: a vertical whip and a loop, both mounted topside over the wing. The marker beacon antenna was under the plane between the landing gear, and the liaison trailing antenna was a single wire wound on an electrically-operated reel located in the forward compartment under the flight deck and controlled by the radio operator.

According to official briefing information given to crews flying out of the Assam Valley in 1943 and 1944, there were at least four ground stations in operation. Tezpur, Jorhat, Chabua, and Ridge Station were all located along the Brahmaputra River within about 200 miles. Tezpur, Jorhat, and Chabua offered ground-to-air transmission facilities on 4220 and 5588 kc (A-3 emission) or 4595 and 8200 kc (A-1 emission). A-1 was continuous wave (CW). A-2 was tone, A-3 was voice. Receiving was done on 4495 and 5588 kc (A-3) or on 4595 and 8200 kc (A-1). Ridge Station transmitted and received on 5588 kc (A-3).

Chabua and Jorhat had homing beacons of 1000-Watt power-emitting tone signals. The Jorhat tower used 1200 kc, Chabua 1070 kc. Tezpur homed the planes on 295 kc with a 1200-Watt source, while Ridge Station brought the birds in on 390 kc from 50 Watts. All bases with direction-finding equipment in the theatre operated receiving-only on 2000-8000 kc, with all three types of emission.

Since the homing facilities and the DF equipment were operated on request only, at least part of the reason for the plight of the Crozier-McCallum C-87 could have been a result of the inability of the crew to call for operation of the equipment.

Even though the plane was equipped with then-modern gear, Spencer, the radio operator, was unable to get accurate bearings. The radio equipment may not be entirely to blame, however. It is known that in 1942 one or more Japanese stations located in Burma succeeded in giving false bearings to several planes flying the Hump. Some planes and crews were lost before the deception was discovered and steps taken to counteract the problem. Weeks later, McCallum and other members of the C-87 were told that the bearings

they received that night might also have been of Japanese origin, though it has never been proven.

In 1944, McCallum wrote an account of the flight that night:

"[After leaving Yunannyi] we flew for some time on the same heading, over an overcast and just flying ETAs (estimated time of arrival). We then changed our heading and were still climbing, finally topping it at 24,000 feet.

"When we had estimated that we were within range of our station [Jorhat], we started concentrating on our radio compasses, which began to reciprocate and were not coming in. Next came our try at the radio range, which was throwing As and Ns at us.

"We went on flying over the overcast and trying to see [ground] lights when we hit a break in the clouds.

"Just to be on the safe side, we decided to have a QDM [bearing] shot... Spencer told them to shoot a bearing and gave them a long call. They came back and told us to fly 278 degrees. This was done via Chabua and Jorhat. We decided this couldn't be right, and Spencer relayed the [Crozier's] question if it was 'reciprocal' or 'to fly.' The answer came back 'to fly.' We flew this for a while trying to get contact and see if there were any lights below. Fifteen minutes went by and another bearing was shot.

"...they gave us the same heading, 'to fly.' We told them they must be wrong... the total flying time on this heading was 40 minutes. Another bearing was shot and this time it was 'to fly' 268. And then another which was the same."

What nobody realized was that the plane had been blown off-course by winds later estimated to be from the south at about 100 mph. By the time they were given the 268 heading, they were probably many miles north of their supposed course.

Suddenly Crozier turned to McCallum. "Mac, does that look like a mountain out there?" "It sure is, and I've got one over here!" Crozier twisted the plane into a sharp bank and one of the mountain peaks flashed by, barely feet away.

Thirty-seven years later, McCallum still remembered: "If we'd had our landing gear down, we'd have left tracks in the snow."

Because of the storm, they were still flying at about 24,000 feet—far higher than normal on the route over the Hump in good weather—and those mountains had loomed higher than the plane. For the first time they realized they were really lost, and McCallum quietly tightened his parachute harness as much as possible without leaving the cockpit.

Spencer called the ground station again; the distant operator asked to have the plane's landing lights turned on. "You're over Chabua, we've sighted you, watch for a green flare," Spencer was told. (McCallum thinks the message was a harmonic with another airfield in the area; harmonics were "quite common at night with HF equipment.") Everybody who could get to a window tried to spot the flare, but instead they saw flickering lights through a break in the cloud cover.

Crozier took the plane down and circled the lights, looking for the Chabua field. It wasn't Chabua below, nor Jorhat, nor any of the other bases in the area—the men couldn't recognize anything except that they were over some city of fair size. They took the plane back to about 20,000 feet and flew for a few minutes while Crozier and McCallum talked over the situation. Fuel was becoming critically low: Planes flying the Hump were given only enough fuel to make their destination and return, with about 45 minutes extra flight time.

They were already long overdue at Jorhat, and even as they talked, Number Two engine sputtered and died. Perram was sent back to make a fuel transfer from one of the other tanks, but before he could begin, another engine coughed, smoothed out, coughed again, and quit. Crozier, as commander of the aircraft, made the decision: They would have to bail out.

Parachute jumps were especially dangerous over the Hump route even in daylight, and night jumps were even more so. In daylight, a jumper had some chance of choosing his landing spot. At night he might land in a tree or be impaled on a clump of bamboo, land in a river and drown, or simply plummet straight to the ground beneath an unopened 'chute—parachutes were just as prone to the weather problems as other equipment. Still, there was little choice for the five men. It was jump and have an even chance at survival on the ground, or stay with the plane to almost certain death.

McCallum trimmed the plane level while Crozier took the rest of the crew to the cargo compartment and prepared to jump, but not before Spencer sent out a distress call and screwed down the sending key. When McCallum left the cockpit for the last time, the altimeter read 17,500 feet, all engines were dead, and the plane was dropping rapidly—a C-87 wasn't known for its gliding ability.

In the rear, McCallum found all four men still trying to get the door off—it had opened about two feet and jammed. McCallum and Crozier wrestled it further open until it fell away from the plane. Crozier, Spencer, and probably Perram exited first (Huffman says Perram and McCallum were still aboard when he left; McCallum says the order was Crozier, Spencer, Perram, Huffman, and McCallum).

McCallum started to the door, realized Huffman didn't have his harness straps properly hooked, and went back to help. They got the harness on, though it wasn't tight enough and there was little time to adjust it. Just as Huffman snapped the final hook, the plane lurched as if going into a spin. McCallum knew that once the plane began spinning, centrifugal force might pin them inside all the way to the ground. He hustled Huffman out the door and followed immediately.

McCallum and Huffman both agree that the scene was one of urgency without panic. They also agree that the time from cockpit to bail-out was about one minute.

McCallum hit the airstream and pulled his ripcord, expecting a long ride to the ground, since the crew still thought they were somewhere over India, or perhaps Burma.

He felt the shock of the 'chute opening, and seconds later hit the ground and was knocked unconscious for an indeterminate period of time. When he came to, his watch had stopped at 10:45 p.m. It was dark, but there was enough light to see that he was sitting on the edge of a precipice.

When the sun came up the next morning, McCallum found himself on the side of a mountain, which the crew later decided was more than 16,500 feet high.

As McCallum took stock of his situation and

checked his equipment, he took the Form 58, the sheet signed by the parachute packer, from the 'chute bag —it was common for surviving jumpers to personally thank the rigger. He didn't have to wait long to do that—it was his own name at the bottom. As Assistant Parachute Officer at Jorhat, McCallum packed one 'chute a month as practice. This month, the 'chute he'd packed had been the one he jumped with.

Within an hour or two, McCallum, Crozier, and Spencer had located each other by shouting. Crozier and Spencer were together 1000 or 1500 feet lower than McCallum and perhaps a quarter of a mile away.

Huffman and Perram couldn't be seen. Huffman had landed in a hole and was dangling by his harness; he could hear the other three, but couldn't yell loudly enough to attract their attention. Despite a badly injured left arm—possibly a broken collarbone—he later managed to pull himself out of the hole, but by then, McCallum, Crozier, and Spencer were gone.

Perram had landed on the far side of the peak; during the next few days, he suffered frostbitten feet, but eventually recovered with no damage.

By the fourth day, both Huffman and Perram had been brought to Tsetang. Both men had been found by Tibetans who already knew of the presence of the other three men in Tsetang.

McCallum, who had been studying Hindustani in his free time, was able to talk to one man in the village —everyone else spoke a strange language he'd never heard before. The three Americans were unpleasantly surprised and shocked to learn they had landed in Tibet, several hundred miles to the northeast of Jorhat. There were no American bases—in fact, no Americans at all—in Tibet. The nearest American base was to the south in India, on the other side of the Himalayas.

By the evening of December 2, 1943, Crozier, McCallum, and Spencer were resting in a nearby village called Tsetang which they had found by following a mule caravan.

For two weeks the men waited in Tsetang while the village elders sent messengers back and forth to Lhasa, the capital city, for instructions on how to deal with the Americans. Tibet was a country isolated not only by physical features, but also by national policy. Almost certainly, no more than five Americans had ever visited the country, though both the British and the Chinese maintained small trade missions in Lhasa, both of which aided the flyers in their subsequent journey through Tibet.

Finally word arrived that they were to go to Lhasa, a three-day trip by horse or mule.

At Lhasa they were stoned by an angry crowd of Tibetans. The Americans couldn't understand why; up to this point, all the Tibetans had been friendly. It wasn't until they arrived at Deyki Lingka, home of Mr. and Mrs. George Sherriff of the British Trade Mission, that George Sherriff explained the problem: When the plane had circled the lights of the strange city weeks earlier, they had been over Lhasa, the Holy City of Tibetan Buddhism and the home of the Dalai Lama, the supreme God to the Tibetans. It was a mortal sin, according to the Tibetans, for anyone to place himself physically above the Dalai Lama, whose home was the Potala, a palace of 1000 rooms looming high above Lhasa. The Americans, unknowingly, had been guilty of a religious transgression.

Because of this sin, fanatical monks were agitating the Tibetan populace in Lhasa, and the Tibetan government insisted it could not be responsible for the safety of the Americans in Lhasa. After only three days in Lhasa (spent inside Deyki Lingka for safety), they were escorted to the edge of Lhasa by a crowd of Chinese officials and Mr. and Mrs. Sherriff, as well as other members of the British Mission.

On their first day in Lhasa, Reggie Fox AC4YN, an expatriate Englishman who later married a Tibetan woman, sent a radio message to China informing authorities that all five men were safe. (McCallum has the telegram received by his mother after the plane was lost, reporting him missing, and another a few weeks later after Fox's message was received.)

Fox's station, AC4YN, was a powerful one, and Fox was able to work as far as Indiana, USA, with the equipment, which probably was powered by a small hydroelectric plant on a river about eight miles from Lhasa. (In the mid-'30s, a Tibetan named Rangang, an engineer educated in England, seems to have almost single-handedly built the power plant, which may have been under contract from General Electric Corporation. Another source says the unit was diesel, but since fuel would have had to be carried in over the mountains by mule, the hydro unit seems more reasonable. There were no autos or trucks, or, in fact, wheeled vehicles of any kind, in Lhasa—except for two circa 1920 autos which no longer ran.)

On the edge of Lhasa, the Americans said good-bye to their newly-met British friends and to the Chinese, and guided by two Tibetan soldiers and a Tibetan cook who spoke some Hindustani, set out for India. On the journey, McCallum served as the group's interpreter, through the cook.

Fifty-two days after bailing out of the plane, the five men were back in Jorhat, by way of Darjeeling and Calcutta. Theirs is believed to have been the second-longest walk-out of any downed crew in World War II—the longest was 93 days.

In 1980, four of the crewmen were still living. Crozier lives in Texas; Spencer went back to Long Island. Huffman is retired and lives in the state of Washington McCallum, who makes his living as a corporate chief pilot, lives in Pennsylvania. William Perram was killed on his first flight after returning from Tibet.

George Sherriff died at his home in Ascreavie, Scotland, in 1967. His wife, Betty, died in 1979. Reggie Fox, still in Tibet in 1948, has dropped from sight.

As for the airplane, #42-107270, she had crashed not far from Tsetang. While the men waited in Tsetang for instructions from Lhasa, they were taken out to the wreckage. The aircraft came down at the edge of the Tsangpo River, which becomes the Brahmaputra in India and flows through Jorhat.

As the men watched, hordes of Tibetans savaged the hulk of the plane for usable metal. One man tried to carry away part of the radio gear but found it too heavy to manage. He seized an axe, hacked the unit in half, and proudly carted away the pieces.

Like many another wreck further south in India or Burma, the skeleton of #42-107270 may still rest along a river bank in a distant country which few Americans have ever seen. ■

Rx and Cx

—easy-to-build substitution boxes

I finally got tired of trying to read the ohmmeter, hold the test leads in place, and turn the potentiometer to find a resistance value that would keep my experimental circuit from going up in smoke.

What I needed was a resistor substitution box. Well, I got out some paper and a pencil and went to work. The circuit shown in Fig. 1 is the result.

By using 28 resistors and switches in the 1-2-3-3 arrangement, I now have at my fingertips—in one-Ohm steps—resistance values of 1 to 9,999,999 Ohms.

Construction of this unit is simple. The resistors are mounted across the switches' terminals. By opening a switch, *that* resistor is connected in circuit.

The switches are arranged in rows of seven across and four down (See Fig. 1). Then the resistor/switch combinations are connected in series. I used slide switches in my unit (I happened to have them on hand).

The rectangular openings were cut out with a nibbling tool and the switches were mounted to the box panel with pop rivets.

With the use of 1% resistors, there is a possible error of ±100k (that's with all resistors in circuit for a total of 9,999,999 Ohms).

With this circuit, there is a possible monetary advantage over conventional resistance substitution boxes which usually require sixty-three resistors and seven ten-position switches to cover the same range.

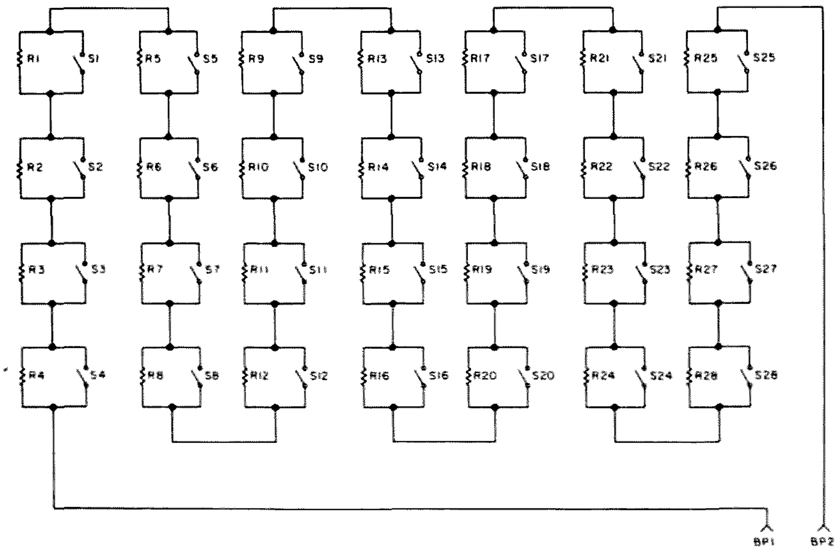

Fig. 1. Schematic for resistor substitution box.

A Capacitor Substitution Box

A ham shack without a capacitor substitution box?

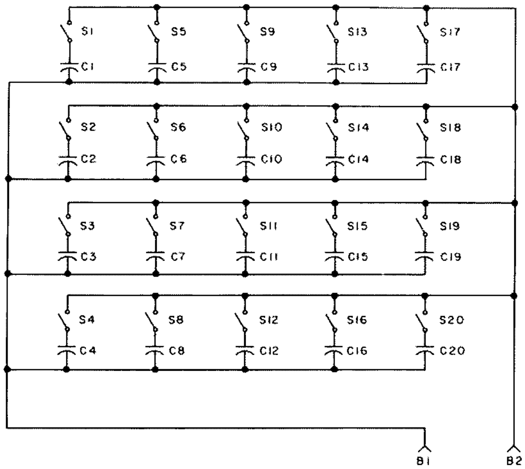

Fig. 2. Schematic for capacitor substitution box.

I don't believe it. Well, I've been wrong before, so, if yours happens to be without one, build this one.

This capacitor substitution box has a range of from 10 pF to within 10 pF of 1 uF, in 10-pF steps. That amounts to 99,999 possible values. This is done with only twenty capacitors and switches. Construction of this unit is simple and straightforward. The capacitors are connected between a common line (B1) and one terminal on each switch. The other terminals on the switches are wired to B2. The switches are arranged in rows of four down and five across (Fig. 2). I used mica (5%) and polystyrene (2%) capacitors in my unit.

Of course, the tighter the tolerance on the capacitors, the more accurate the unit. ■

Don't Be Sunk by Heat Sinks

—a painless introduction to heat-transfer physics

Konrad Roeder WA4OSH
8401 Spain Rd. NE, #9-A
Albuquerque NM 87111

Application

Find the right heat sink for an LM309K voltage regulator IC. The maximum input voltage is 10 volts, the output voltage is to be held at a constant 5 volts, and the maximum current to be drawn from the supply is 1 Amp.

Step 1: Write down the formula:
$R\theta_{SA}(max) = (T_J - T_A)/P_D - R\theta_{JC} - R\theta_{CS}$.

Step 2: Calculate P_D:
$P_D = (Vin - Vout) \times I(max)$
$P_D = (10\ V - 5\ V) \times 1\ A = 5$ Watts

Step 3: Find $T_J(max)$ and derate by 50° C. The data sheet gives us a figure of 125° C for the absolute maximum operating junction temperature; derating that figure by 50° C gives us 75° C for $T_J(max)$.

Step 4: Find $T_A(max)$. The maximum ambient temperature is 25° C, 5° C above room temperature of 20° C.

Step 5: Find $R\theta_{JC}$. Keep in mind that the LM309K is an IC, not a transistor. The data sheet reveals a figure of 3.0° C/W for $R\theta_{JC}$. For transistors, Table 1 is fairly accurate, but for ICs, watch out!

Step 6: Find $R\theta_{CS}$. Since the case is ground on the LM309K used as a fixed 5-volt regulator, we will not need an insulating washer. To improve the heat transfer between the device and the heat sink, we will use some heat-sink compound. From Table 2 we obtain a value of 0.1° C/W for $R\theta_{JC}$.

Step 7: Plug the values into the formula:
$R\theta_{SA}(max) = (75°\ C - 25°\ C)/5\ W - 3.0°\ C/W - 0.1°\ C/W = 6.9°\ C/W$.

Step 8: Pick a suitable heat sink. Choose the next lower value for a TO-3 type case. The RCA-SK KH3423 looks suitable with a $R\theta_{SA}$ value of 5° C/W.

For years I have been resorting to B.F.I. (Brute Force and Ignorance) when designing transistor projects. Mainly, this meant using the biggest heat sink I could afford or watching my project go up in smoke. After the loss of a few precious power transistors, I set out to find out all about proper heat sinking. The principle behind picking the right heat sink is rather simple.

In this article, we will explore heat-transfer physics, interfaces, and practical heat-sink choices. First, let's look at how heat sinks work.

Theory

Heat-transfer physics is a scary-sounding phrase for something that some hams don't think they know about, although they know of something similar: basic electricity. Fig. 1 shows the analogy between thermal resistance and ohmic resistance.

In electrical circuits, whenever there is a difference of voltage between

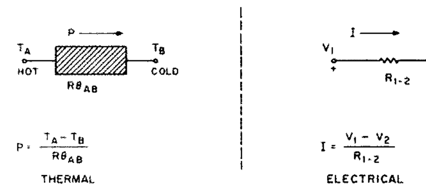

Fig. 1. The electrical analog of heat transfer.

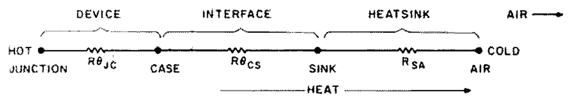

Fig. 2. The electrical analog of heat transfer from the junction of the semiconductor to ambient air ($R\theta_{JA} = R\theta_{JC} + R\theta_{CS} + R\theta_{SA}$).

two points, or nodes, current is said to flow from the more positive node to the more negative node. The amount of current that flows is inversely proportional to the resistance between the two nodes.

Similarly, in thermal circuits, whenever there is a difference of temperature between two bodies (T_A and T_B) or between two portions of one body, heat (P) is said to flow in a direction from higher to lower temperature. This heat flow is expressed in Watts. The amount of heat which flows when a given change in temperature is applied will be found to vary with what is called the thermal resistance of the material ($R\theta$). The lower the thermal resistance of the material, the greater the heat it transfers. Thermal resistance can be expressed in terms of degrees centigrade per Watt (°C/W).

Applying the Theory to Heat Sinks

In semiconductors, heat is produced at the junction of the differently-doped silicon materials. To escape the semiconductor, heat travels from the junction through the case, the interface, and the heat sink into the ambient air. The heat sink dissipates the heat into the surrounding air by means of radiation and convection. The whole system can be represented by the electrical equivalent circuit shown in Fig. 2.

The total thermal resistance from junction to air is the sum of individual thermal resistances: junction to case ($R\theta_{JC}$), case to sink ($R\theta_{CS}$), and sink to air ($R\theta_{SA}$). Applying the analogy found previously, we can say that $P_D(max) = [T_J(max) - T_A(max)]/R\theta_{JA}(max)$, where P_D is the maximum power dissipated by the device in Watts, T_J is the maximum junction temperature in °C, T_A is the maximum ambient temperature in °C, and $R\theta_{JA}$ is the maximum thermal resistance from junction to ambient air in °C/W. With a little algebra, we can combine the two formulas found above and get a very useful equation for finding the correct heat sink. In this equation, $R\theta_{SA}(max) = [(T_J - T_A)/P_D] - R\theta_{JC} - R\theta_{CS}$.

Although manufacturers list maximum junction temperatures of 150°-200° C, it is a good design practice to operate the device at a much lower temperature. To ensure plenty of leeway and extend the useful life of the device, use a maximum junction temperature of 50° C less than the manufacturer's listed maximum junction temperature.

There are several ways of obtaining the maximum power dissipated by the device. A simple way of calculating the power dissipated is: $P_D(max) = P_{input} \times (1 - eff)$.

Another way of calculating the power dissipated is: $P_D(max) = I(max) \times E(max)$.

In some cases, the actual power dissipated may be less than these values, but keep in mind this is a worst-case figure.

The thermal resistance from the junction to case ($R\theta_{JC}$) depends mostly on the type of case that the device is packaged in. Although it is best to obtain the value from the data sheet for the transistor or semiconductor device, Table 1 shows some typical values if the data sheet is unavailable.

The thermal resistance from case to sink ($R\theta_{CS}$) depends on a handful of factors: the type of washer used (if any), the tightness of the transistor or semiconductor device against the heat sink, and whether or not silicone thermal paste or heat-sink compound is used. Some approximate values are shown in Table 2.

It should be fairly obvious why thermal joint compound is important. These zinc oxide and silicone oil mixtures reduce the high thermal resistance of the air gap between the case and the heat sink. But be sure to use it sparingly; the paste has a large thermal resistance and it is important to keep the layer as thin as possible.

Case	$R\theta_{JC}$
TO-3	1.5
TO-5	30.0
TO-18	150.0
TO-36	0.7
TO-39	35.0
TO-66	7.0
TO-92	125.0
TO-220	4.0

Table 1. Typical values for $R\theta_{JC}$ for common case styles.

Washer	Paste	No Paste
none	0.1	0.2
beryllia	0.2	0.4
alumina	0.3	0.5
mica	0.4	0.8

Table 2. Approximate values for $R\theta_{CS}$.

A list of commonly available heat sinks and their thermal resistances ($R\theta_{SA}$) is shown in Table 3. The thermal resistance of heat sinks can be improved or lowered by improving the heat-sink-to-air interface. When the ambient air moves, it more readily accepts heat; thus, some benefits can be gained from a fan blowing across the fins of the heat sink. Also, a change in color can decrease the thermal resistance of a heat sink. A thin coat of flat black paint (such as barbecue black) sprayed over a shiny aluminum heat sink lowers the thermal resistance by about 25%. For a real application, see box.

Conclusion

Although calculations in finding the right heat sink can be much more complicated, this article was written to simplify heat transfer physics as much as possible for the amateur or radio experimenter. Hopefully, the reader will be able to pick the right heat sink for the right job with the guidelines presented here. ■

Tracker — The Ultimate OSCAR Finder

After a few weeks of "sensory overload" playing games with our new 16K Level II TRS-80 systems, both Dennis and I realized that there was a huge untapped potential inside that rather innocent-looking case. What better way to tap it than to harness the power of the computer to make our hobby a lot more fun by allowing us to operate more and calculate less?

Having both cut our teeth on KIM-1™ systems, and having built them up to the degree of having BASIC programs running on them, we decided that translating some of those programs over to the TRS-80 would be a good way to familiarize ourselves with its capabilities.

The first of the translations undertaken was the program we wrote to track the OSCAR satellites. Considering that both of us are AMSAT members and OSCAR enthusiasts, it seemed like the logical thing to do. Besides, anything that we could use around the shack was bound to be more fun than another game.

Satellite Tracker is Born

"Tracker" is the fruit of that labor. This program will allow you to use your Level II TRS-80 to track OSCAR 7 and 8 (or any satellite in a polar orbit). Using only the Reference Orbit information published monthly in *73 Magazine*, *QST*, or ARRL bulletins, Tracker will compute the orbits for the day, the time and longitude of each pass (its EQX), and azimuth and elevation data for your steerable beam arrays.

In addition, some slick features have been added that weren't in the original KIM-1 program. For instance, you may now enter a second station's latitude and longitude and Tracker will compute a "Mutual Visibility Window" indicating when the stations will have simultaneous access on any given pass (great for those DX orbits). Line printer routines for hard copy have also been added and will support non-Radio Shack printers as well as the parallel-port Cen-

tronics types. Automatic "sequential tracking" will allow you to track any number of orbits in a row from only one EQX or you may enter the specific orbits you wish to be tracked from the keyboard. Tracker has been extensively tested and should be completely crash-proof (but Murphy always can pay a surprise visit).

What You Need to Make It Work for You

Tracker will run on any Level II TRS-80 system, either cassette- or disk-based, having at least 16K of RAM. Hard copy is available for those of you who have a line printer, but you don't need one to run the program. Because of the length of the program (12K, more or less) and the use of Level II's built-in trig functions, Level I systems or Level II systems with less than 16K are not suitable.

For you die-hards who insist on typing in everything, the program listing is reproduced here for your convenience, but the rest of you take heart. If you feel that 12K of Level II BASIC is a bit long to type in and debug (and we agree wholeheartedly), cassette tapes are available.

Using Tracker with OSCAR

Using Tracker may look complicated at first glance, but it really isn't. Rather than enter into a detailed description of the program's execution right off, I'll just cover the major sections and how they function. Flowcharts will be

used to assist you in understanding the logic of the program. A reference chart has been provided, listing the functions by line numbers for those of you who might want to modify it (although I really can't think of anything we have left out).

Tracker in Action

To compute and track all orbits of either of the polar OSCARs (or other polar satellites) for any given day, the only information you will need is the time and longitude (EQX) of the reference orbit for that day. This data is available in most of the monthly amateur publications and also is available from AMSAT Orbit Calendars and in daily bulletin transmissions over W1AW.

To make things easier, the main logic has been divided into two sections: Orbit Cycle Compute and Orbit Track. The functions and differences of these two routines are described in the following sections. To select Orbit Cycle or Orbit Track, Tracker will prompt:

DO YOU WANT A DAY'S CYCLE OF ORBITS (Y/N)?

A YES or Y answer will select Orbit Cycle and a NO or N will select Orbit Track routine. Flowchart 1 details the main selection logic.

Orbit Cycle

Given the EQX of a reference orbit (the first orbit after GMT midnight, generally), Orbit Cycle—which is *not* a moon bike—will compute and display the EQX data for every orbit of that satellite in the 24-hour period following the reference orbit. This data will be used later in Orbit Track, so you might want to jot down the orbits that look good to you. This routine is provided mostly as a convenience for those who need to generate a list of the day's orbit times. Flowchart 2 details the Orbit Cycle logic, and Flowchart 3 details the logic used to select a satellite for cycle or track, called Setup. Fig. 1 shows a typical Orbit Cycle printout.

Orbit Track

The Orbit Track routine is the main body of the program. Orbit Track will take EQX data entered from the keyboard by you (and probably computed by Orbit Cycle) along with orbital parameters for the satellite of interest and the location of your station and will compute and display, on a minute-by-minute basis, the visibility of the satellite. It also will produce azimuth and elevation headings from your station location, the latitude and longitude of the sub-satellite point (the point on the Earth's surface directly under the satellite), and the direct distance from you to the satellite, in kilometers.

Phew . . . Wanna try doing all that on your little four-banger and still get ready for that 6:20 pm pass while the XYL is screaming *"DINNER'S READY"* and the kids want to know when you can fix that broken bike? You get the picture!

You may make a selection from the pre-programmed satellites (OSCAR 7, OSCAR 8, or RS-1), or Tracker will accept your own orbital parameters to facilitate tracking other polar orbiting satellites, like the NOAA weather birds. This is accomplished by the "User Input Routine" (see

Flowchart 4). Once entered, these user orbit parameters will be retained during the program run until you change them. Fig. 2 shows a typical input run.

After you have selected your bird, Orbit Track will prompt for entry of the EQX data and for selection of the various options described below. (See Flowchart 5 for Options logic). After setting your option choices, the orbit track commences.

Orbit Tracking Options

In Orbit Track there are several options that may be set or reset for each orbit computed. Flowchart 6 shows Orbit Track logic. These include listing the computed data on the line printer (hard copy), suppressing the display of data for minutes when the satellite is not visible from your station location (PRINT VISIBLE MINUTES ONLY), and tracking the orbit for simultaneous access from a second station location (M.V.TRACK). Each of these options has a default mode, which the computer will select if you respond with just an ENTER after the prompt for that option. All of the options may be set or reset before each orbit tracking operation, so you won't be stuck with a selection you don't want.

In the PRINT VISIBLE MINUTES ONLY mode, Tracker will print a single line indicating the current time and (satellite name) NOT VISIBLE until the satellite comes into the range of your station location. It then will output all data normally. When it has computed that the satellite has dropped below your horizon, it will end the tracking routine for that orbit and ask if you wish to track the next orbit of the same satellite. This is the "Sequential Tracking" feature. Fig. 3 shows the abbreviated

nature of PRINT VISIBLE, contrasted against Fig. 4 showing the same orbit printed with the PRINT ALL MINUTES option.

Selecting the PRINT ALL MINUTES option will force Tracker to print data for the entire duration of the orbit selected without regard to the visibility of the satellite. With either option, if the program cannot find any time during the orbit when the satellite is within range, it will indicate that the satellite is NOT VISIBLE THIS ORBIT.

The HARD COPY option is pretty self-explanatory, but a word or two about its operation will help. The TRS-80's Line Printer routine will lock out your BASIC program if you issue an LPRINT command without a printer hooked up. To prevent this from happening and to support some of the after-market printer adapters (like the TRS-232 that I used here with my Anderson-Jacobson 841 Selectronic to type this article), Tracker samples the Printer Port for a READY signal. If it senses that the printer is off-line or that there isn't one there (the two conditions look identical to the computer), it will prompt:

PRINTER OFF-LINE . .
CANCEL HARD COPY
(Y/N)?—

Answering YES will reset the HARD COPY flag and cancel all further attempts to LPRINT. Answering NO will keep the HARD COPY flag set and will attempt to LPRINT the data requested. If you have a Centronics-type printer that uses the Expansion Interface printer port, this message will remind you to turn it on and get it ready. If you have the TRS-232 or a similar adapter that uses BASIC's Printer Device Control Block as a link to its machine language driver, this little option is not

Table 1. Symbol table for Satellite Tracker.

AN$	General-purpose input string. Contains keyboard input in response to prompts.
AZ	Antenna azimuth calculated each minute, in radians.
CO	Crossing longitude . . . from EQX input.
DC	Westward precess of orbit . . . used to update CO for "Sequential Tracking" function.
DG	Conversion constant (radians * DG = Degrees).
DS	Distance to satellite, calculated each minute, in km.
EL	Antenna elevation calculated each minute, In radians.
ET	Elevation seen from "Target." Used with "M. V. Track."
F2	PRINT LENGTH FLAG =1 means PRINT VISIBLE MINUTES. =2 means PRINT ALL MINUTES.
F3	VISIBLE FLAG =1 means bird visible once this orbit. =0 means bird not visible this orbit.
F4	CYCLE FLAG =1 means ORBIT CYCLE only. =0 means TRACK.
F5	HARD COPY FLAG =1 means NO HARD COPY. =0 means HARD COPY REQUESTED.
F6	M. V. TRACK FLAG =1 means NO M. V. TRACKING. =0 means TRACK.
H,H$ M,M$ S,S$, TM$,T, ST	Used in time conversion routine. Time is computed in decimal, then converted to strings for printing. H = Hours. M = Minutes. S = Seconds, TM$ = Composite.
HT	Height of satellite's orbit, in km.
IN	Inclination of satellite's orbit.
PR	Period of orbit.
LA	Your station latitude in decimal degrees.
LO	Your station longitude in decimal degrees.
SL	Latitude of sub-satellite point.
SO	Longitude of sub-satellite point.
TA	Target station latitude for "M. V. Tracking."
TL	Target station longitude for "M. V. Tracking."
OO	Angle, Theta, between satellite, center of the Earth, and you. Used to determine position of bird.
RD	Conversion constant (degrees * RD = radians).
SA$	Name of satellite being tracked.
US$	Name of "User" satellite that has been input.
W,X,Y, Z,ZT,P, HP,P2	Are either intermediate calculations to derive one of the above, or are system variables which do not change value.

necessary. If you don't have a printer, this little warning may save you some grief. Remember, if you do force the issue, and don't have a printer or other adapter, BASIC will lock you out of the program for good (or at least until you RESET).

Two Tracks for the Price of One

The MUTUAL VISIBILITY TRACK option is a feature that was not in the original KIM program. If you answer YES to this option, you will be prompted to input the latitude and longitude of a "Target" location. You can use this option for things like tracking a pass to see if that G3 station can hear OSCAR 8 when you can, or even to see if your buddy in North Dakota can access the same orbits as you. You will find it convenient and easy to use, and it will make working satellite DX a lot less chancy and a lot more fun. To indicate that this option is operational, the header printout will now include:

* = WINDOW OPEN TO (LAT), (LONG)

The program printout will be modified to print an asterisk (*) next to the time column for each minute when both stations have access to that satellite. See Fig. 5 for a sample printout. Tracker will retain the location of your target station and will allow you to update it or keep it the same each time you select the M.V. TRACK option. This makes it a snap to track more than one orbit for the same target.

Additional Features

Another slick feature of Tracker is sequential tracking. To eliminate repetitive data entry (and the inevitable sore fingertips), the Orbit Track routine is programmed to compute the EQX for the next orbit in normal sequence. After tracking any orbit, the computer will prompt:

COMPUTE NEXT ORBIT OF (satellite name)?

A YES answer will tell Tracker to update the EQX data to the next orbit in normal sequence and offer you the options selection for that orbit. A NO answer will bring the prompt:

ANOTHER ORBIT FOR (satellite name)?

A YES answer will retain the satellite selected but will allow you to input another EQX and track it. Use this when you wish to skip certain orbits that are of no interest to you (like when it is 5:00 am and the satellite is passing over southern Borneo, or some other exotic port-of-call). A NO answer returns you to the main menu. To fully appreciate the versatility of the options, note that Figs. 3, 4, and 5 are tracks of the same orbit, but printed with different options.

Some Niceties

During development of this program it became apparent that some tricky timing problems can occur for stations located close to the equator. These stations may experience a "wrap-over" of a visible pass from the southern to northern hemisphere, or vice versa. To eliminate this, Tracker monitors the status of any Orbit Track listing and if the satellite is still visible as it crosses the equator, Tracker will extend its computations across the equator until it loses visibility for that pass.

Slippery-Finger-Proof, Too

Tracker also monitors the values for all user entries from the keyboard and will print error messages as appropriate. You will not be allowed to make mistakes by entering a value that is too large or too small for the desired function, and you may even find Tracker questioning your input to the User routine if the parameters don't make sense. Believe me, after playing with some programs where there is no provision for error correcting, sometimes making the en-

tire output useless, using Tracker is a pleasure. Fig. 6 shows typical input error messages, and Fig. 7 shows User Input Routine error messages.

Input/Output Conventions

It should be understood that in OSCAR tracking, longitude is expressed as West only, from 0 to 360 degrees. Latitude is expressed as either +1 to +90 or −1 to −90 for North or South, respectively. Tracker printouts follow these conventions. All longitudes displayed are West. To find the correct East longitude for numbers exceeding 180 degrees, subtract 360 from the indicated West longitude. All latitudes are displayed as *positive* numbers for North and *negative* numbers for South. Your input to Tracker should follow this convention too, or you may get some very strange results.

Tracker will compute orbits for stations in either hemisphere as long as the above standards are followed in inputting station and target locations, etc. Tracks computed for southern hemisphere stations may take a while before they show output since Tracker uses a complex iterative method to compute the data for each minute of the orbit and cannot fast-forward these calculations. Since it begins each orbit calculation at the northbound equator crossing, it must compute between 40-50 minutes worth of data before it "wraps over" into the southern hemisphere. Be patient. It's still faster than a hand calculator. Just remember that the EQX data should be entered for a northbound equator crossing regardless of the hemisphere in which your station is located.

So How Does It Work?

For you programmers out there, Table 1 is a symbol table of the variables used and their significance to the program. Each of the flowcharts shows the BASIC line numbers of the program sections on that chart and where the jumps go. In addition, operations that change variables will have those variable names shown next to them, indicating changes. You should be able to use these aids to follow the program just about anywhere in its execution. If all else fails, use the TRON function of Level II BASIC to show you the line numbers as you are executing Tracker.

Some Final Notes

Dennis and I hope that you enjoy using Tracker on your TRS-80 system. The program is written in Microsoft's Level II BASIC and can be translated into other BASICs that have the trig functions with only minor syntax changes. Versions are available for the PET (yes, it will run on the 8K version) and APPLE (16K with APPLESOFT). And the updated KIM-1 version will also be available. As interest arises, we will translate Tracker into versions suitable for other micros as well.

As indicated before, cassettes for the TRS-80 (and for the PET as well) are available from GNOME Computerworks, at the address listed under our names. The price is $10.00, postpaid, and includes a user's guide that should answer any questions this article may have left unanswered. (We have other ham software goodies available, too. Please inquire.) For now, 73 from us both, and see *you on OSCAR.*■

You Still Haven't Built a Logic Probe?

—try this one

Many people who get involved in home computer systems or any other form of digital electronics at one time or another run into hardware problems. If you want to fix them yourself, you need some way to look at what's going on inside the logic.

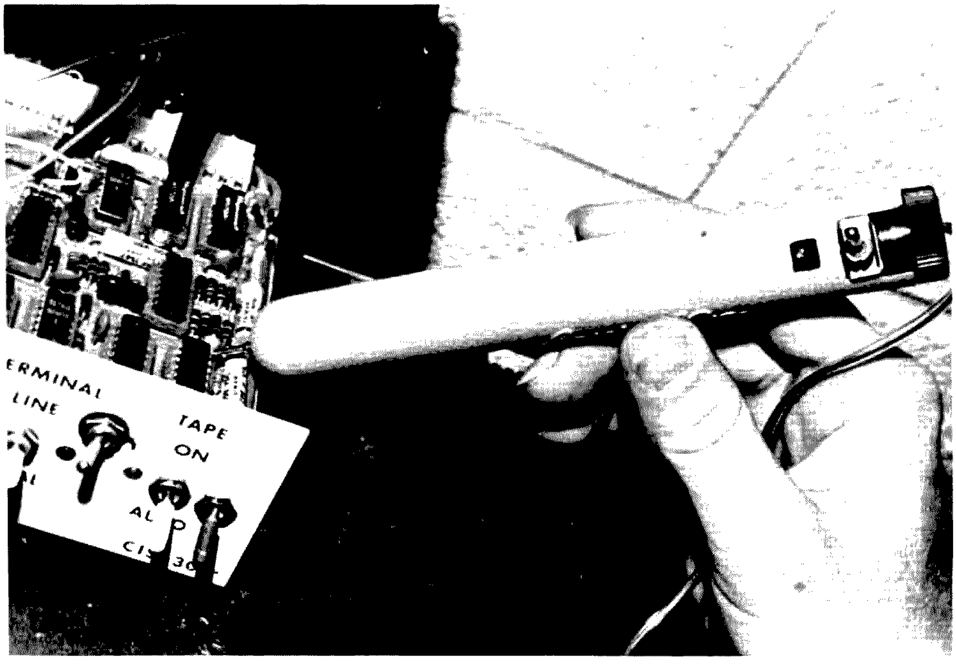
Usually, if you want to see logic levels, you might use a simple logic probe or a high-impedence FET (Field-Effect Transistor) volt ohmmeter (VOM). If you want to see a timing relationship, you need a triggered sweep oscilloscope to see the actual timing relationship of two different pulses or signals.

Not every home computerist can afford to buy a good scope just to look at a logic signal once in awhile, so here is a unique logic probe which can see timing relationships as well as perform the usual functions of a logic probe. It's inexpensive, with provisions for both positive and negative sync input. It can almost replace an oscilloscope in many digital applications. If you don't have an oscilloscope and can't afford one, then this logic probe is a useful substitute.

At work and at home I use my Synchronized Logic Probe to identify most logic problems easier and faster than with a scope. Many times it's too much trouble to pull out the scope, so I use this probe instead. My probe also has features missing in an oscilloscope. Did you ever try to see an 18-ns pulse on a scope when it only happens about once every 5 or 10 seconds? With a scope, such a pulse is invisible, but using a probe which stretches the pulse enables it to be seen.

This logic probe will display a P for approximately 0.75 seconds every time a pulse occurs. It also displays standard logic levels like L for a low (false), H for a high (true), and an F for a float (open). Not only that, you can synchronize it to one signal and see if another signal happens at the leading or trailing edge of the sync input. One of the nicest points about this logic probe is that you can build it for about seven dollars.

How does this work? See the schematic, Fig. 1, and the timing diagram, Fig. 2. Under all conditions, segments E and F are always enabled via the +5-volt power bus forming the left-hand vertical bar of P, L, H, or F. The first condition discussed will be the static or no-signal condition.



The completed Synchronized Logic Probe in action. Custom case is a cigar tube.

At this time, the probe tip

is connected to neither a ground nor a true value. Pin 1 of IC1A is floating (true in TTL) and pin 2 is connected to a true (Vcc) through S1 and J1 (Sync input), giving a false output of IC1A. Pin 13 of IC1D is at ground potential through R6, and pin 12 of IC1D is also true through S1 and J1, so the output of pin 11 is true. The false output of IC1A is applied to both inputs of IC1B, making its output true.

This true is applied to one input, pin 9, of IC1C. The other input, pin 10, also is true from the output of IC1D, so now IC1C has an output which is false. This false is applied to input pin 12 of IC2D. The other input is tied to the $\bar{Q}$ output of the one-shot, IC4, which is statically true. The output of IC2D is logic true, which causes segment A of the display to be lit. To complete an F, we need to light segment G and make sure segments B, C, and D are off.

Pin 9 of IC2C is true from the output of IC1D and pin 10 of IC2C is true from the one-shot, making its output false and thus keeping segment B off. Pin 3 of inverter IC3B is true from IC1, making its output false, which, when applied to IC2B, makes its output true.

This output is inverted again through IC3C and makes segment C false, thus keeping its segment off. Pin 1 of IC2A is false from IC1A, making its output true and lighting segment G; this output is also inverted by IC3D, keeping segment D off. Thus, segments A, E, F, and G are lit while B, C, and D are off, giving a display of F (float).

Now that we have seen the float condition and the basic operation, I am going to explain the logic true or high condition. When a logic true is present at the probe tip, it is applied to pin 1 of IC1A, making its output false. This false output is

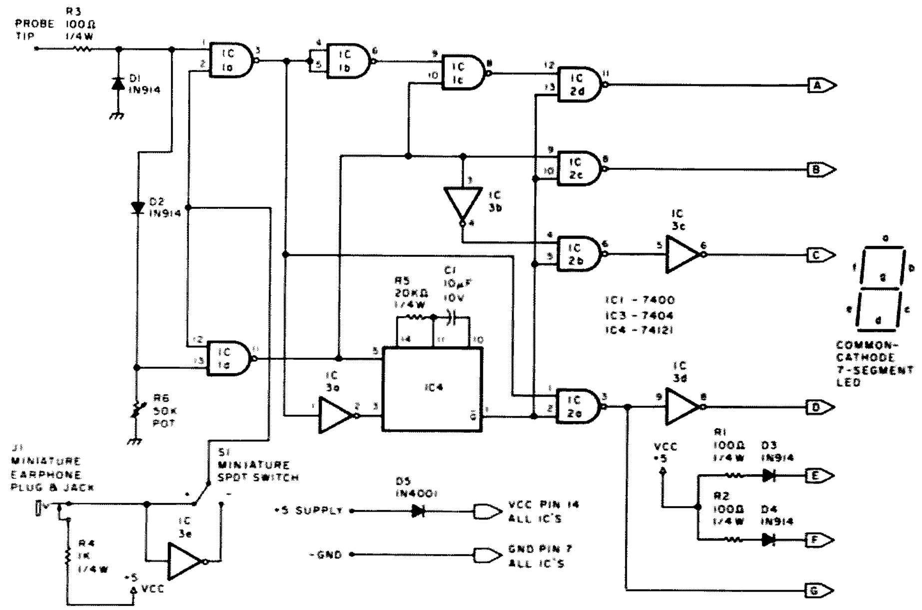


Fig. 1. Schematic diagram of the Synchronized Logic Probe.

applied to both inputs of IC1B, making its output true, which is then applied to pin 9 of IC1C.

The probe tip input is also applied to pin 13 of IC1D, making its output false and this being the other input to IC1C, thus makes its output true. This true which is applied to one input of IC2D along with a true on the other input from the $\bar{Q}$ output of the one-shot makes the output of IC2D false, which turns segment A off. Pin 9 of IC2C is false from IC1D, making its output true and lighting segment B. Pin 4 of IC2B is true from the inverted output of IC1D, making the output of IC2B false, which is inverted by IC3E, lighting segment C. Pin 1 of IC2A is false from the output of IC1A making the output of IC2A true, which is used to light segment G and is also inverted by IC3D which keeps segment D off. Now we have segments B, C, and G lit, while segments A and D are off. Remember that segments E and F are always on and thus the display of H for a static true.

As for the low condition, all segment outputs are opposite except for segment

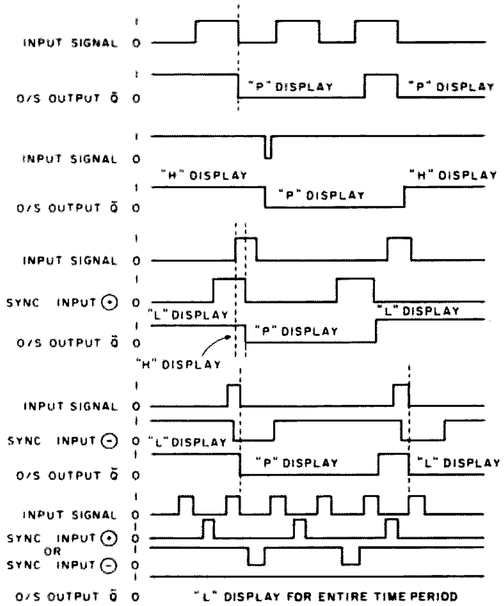

Fig. 2. Timing diagram for logic probe.

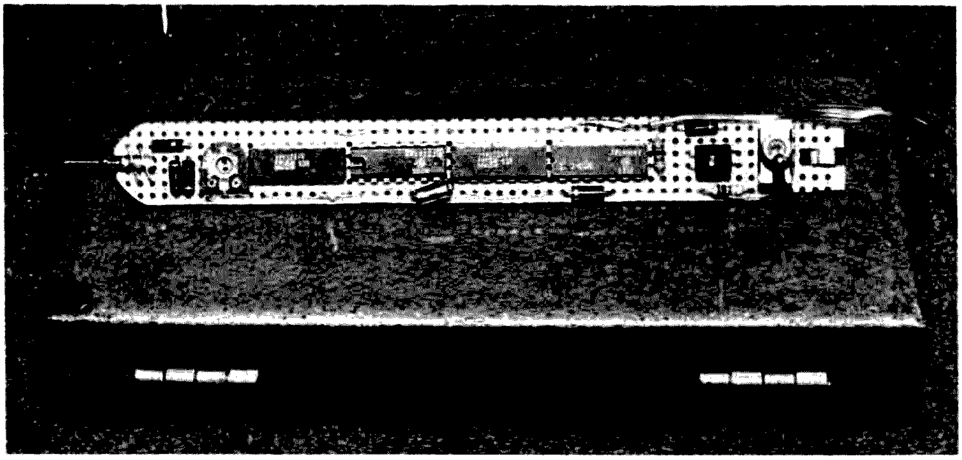
A, which remains off. Pin 1 of IC1A goes false, making its output true. This is inverted by IC1B, so a false is applied to pin 9 of IC1C along with a true from the output of IC1D. This makes the output of IC1C true. This is then applied to pin 12 of IC2D, along with a true from the $\bar{Q}$ output of IC4, which makes the IC2D output false. This keeps segment A off.

A note about the low condition: When you first apply the probe tip to a logic false signal, the changing state of IC1A through IC3A triggers the one-shot, making the $\bar{Q}$ output false. This, in turn, enables segments A, B, and G regardless of the other inputs and also disables segments C and D, thus displaying a P for approximately .75 seconds before going to an L display. This can be viewed as a self-checking way to see if



Components are mounted on 0.1" perfboard shaped to fit inside cigar tube.

the pulse circuit is working. Whenever there is a high-to-low transition at the input of IC1A, the one-shot will be triggered and a P will be displayed until a constant state is reached. This covers the generation of the H, L, P, and F display conditions. Note that the length of the P display can be changed by varying R5 and/or C1.

This brings us to the operation of the sync input. Under normal conditions (not using sync), switch S1 is kept in the positive (+) position, thus applying a logic true to one input of IC1A and IC1D. When the sync-pulse input is used, the logic true is disconnected from the switch input and replaced by the sync-input signal.

First the positive sync input will be discussed. When using the positive sync input, this means that we are looking for a signal at the probe tip which is either occurring at the leading edge (low-to-high transition) of the sync pulse or during the true state of the sync pulse. When the sync pulse is true, it is applied through the switch and enables the inputs to both IC1A and IC1D. If the signal you are looking for at the probe tip becomes true at the same time or during the time of the sync pulse, a P will be displayed, indicating that the logic true was present. This is accomplished by the changing states of IC1A and IC1D which trigger the one-shot, IC4. If the signal you are looking for was not true during the sync pulse time, an L will be displayed and remain.

When using the negative sync input, this means that you are looking for a signal at the trailing edge of a sync pulse or during the time that the sync is false. The first thing to do is to move the switch (S1) to the negative position. When the sync pulse goes low at its trailing edge, it is applied to pin 11 of IC3E, making its output true and thus enabling IC1A and IC1D. If the input signal goes true during that time, the pulse circuit is triggered and a P is displayed, indicating that the pulse was there at that time. When you are not using a sync input, switch S1 must be kept in a positive position or the normal probe functions will not work correctly. Also, when the sync input is used and the probe tip is floating, a P will display if the sync input is active.

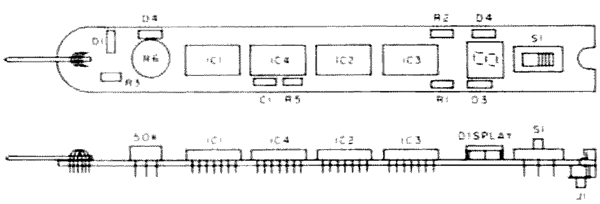


Fig. 3. Synchronized Logic Probe component mounting.

Construction

Fig. 3 and the photos show the complete circuit of the Synchronized Logic Probe, but there are a few things that might prove to be helpful. The prototype of this probe was built using 0.1" perfboard which was cut and shaped to fit inside a cigar tube prior to mounting any of the components. Wire buses were used for the +5-volt and ground connections for the chips and other components. As shown in Fig. 3, you should mount the display, switch, and sync jack on the end of the board first, and make any necessary cutouts on the tube housing and board. Make sure that switch S1 is easily accessible and sticks up through an opening in the tube.

There is only one adjustment on the probe—the 50k variable resistor used to establish the F state. When you get the probe assembled, connect it to your power supply and note that there is a legible display (L, H, or F). You should adjust the potentiometer until an F is displayed with no connection to the probe tip. Once this is obtained, you will notice that there is a range of adjustment before the display changes from an F to an L or H. This adjusts the sensitivity of the probe tip to a logic high or low.

Upon completion, touch the probe tip to the +5-volt side and then to the ground side of the power supply that you are using. The probe should display an H when touched to the +5 volts. A P should be displayed for approximately .75 seconds when first touched to ground, before going to an L display. If a P is not displayed when the probe tip is first touched to ground, the pulse circuit is not functioning correctly. As long as the other displays are correct, then the problem should be in the one-shot (IC4). Check the external capacitor and resistor connections to the chip. If the other displays do not work correctly, then you will have to troubleshoot the entire circuit.

A neat trick for troubleshooting can be used if you have a display with a decimal point: Connect a piece of wire approximately 10 inches long through a 100-Ohm resistor to the decimal point and use it for a simple probe. If you touch the wire to a logic high, the decimal point will light, and if it is a low the decimal point will stay off. The 100-Ohm resistor in series with the wire is to prevent burning up the decimal point.

I used this basic logic probe when troubleshooting the more sophisticated, Synchronized Logic Probe. This, along with the circuit operation and schematics provided, should give you everything you need to build and troubleshoot the Synchronized Logic Probe. Good luck! ■

VHF Contesting

—a magnificent obsession

There are several things this article *won't* say. For starters, I will not tell you that VHF contesting is easy. Nor will I guarantee any kind of success if you try it on your own. Instead, I will tell you about all the fun you are missing if you don't already participate in VHF contests; even if you are not interested in trying out this madness, you should be happy to hear that life does exist above two meters.

Having antennas that clear the trees is important, but the W8DJY contesters rely on a knowledge of VHF propagation to supplement their line-of-sight capability.

Cornfields

Until a few months ago, I thought that VHF contests were intended for hams living in the East or in the West. After all, that is where mountains are, and the densely populated areas, too. Those hams living in the flat Midwest were just plain out of luck since most VHF contacts are made using a line-of-sight path.

A 45-minute drive through the rolling countryside of southwestern Ohio to the station of W8DJY was what it took to convince me that VHF contesting not only exists in the Midwest, but also it is doing quite well. W8DJY is located on one of the taller "peaks" near Middletown, Ohio. It sits about 200 feet above most of the surrounding terrain, at an elevation of 850 feet.

What W8DJY lacks in height is partly made up for by a jungle of aluminum. An antenna "plantation" is probably the best way to describe it. There is no stately white mansion in the middle; instead, you will find a one-story shack devoted to VHF contesting. Rather than trotting off to a mountain for a couple of weekends each year, the

A mix of home-brew and commercial equipment is used to give W8DJY a big signal on 220 MHz.

W8DJY spares his family from the squeaks and squawks of ham radio operating by having a separate shack. Inside, there are operating consoles for each of the VHF bands. The 6-foot dish was constructed for less than $100 and will be used on 1296 MHz.

These hams are part of New England's smallest telephone company, "Mountain Bell." It exists for only one weekend each year. The large tower in the background is part of a fire lookout, not W1FC's contest effort.

W8DJY ops spend their time perfecting this fixed station—one that they can use year 'round.

The inside of the shack looks a lot like what you and I might have. There is a smattering of Drake and Collins HF gear and the usual collection of QSL cards. A closer look at the cards tipped me off, however, that this station, despite its appearance, is not like yours or mine. There is a card from Japan on the wall.

"So what, I've worked a million of those guys on ten meters," you say.

Yeah, but how many have you worked on six meters?

Most of the HF gear is used with receive and transmit converters on the UHF and VHF bands. W8DJY's owner, Brownie, prefers tube-type rigs because they are less susceptible to intermod, something that becomes important when you have four separate kilowatt signals generated within a few feet of each other. Brownie patiently explains that you need every Watt up to the legal limit on 6, 2, and, if possible, on 220 and 432 MHz. Unfortunately, you can't just pick up a kilowatt amplifier for 432 at the local Radio Shack; it's time to break out the schematics and a soldering iron.

Back at the antenna farm, I noticed that it has been designed to squeeze the most from each of those precious UHF Watts generated inside. Hard-line is considered a necessity rather than a luxury. Strangely enough, the W8DJY gang does not try to get the antennas as high as possible. Instead, they compromise between line loss, increased height, and propagation demands. The six-meter array, for example, is a pair of 11-element beams spaced 18 feet apart, only 36 feet off the ground. This, I am told, is part of the 54-MHz secret.

Secret on Six

One might think that W8DJY and other midwestern stations have three strikes against them before a contest even starts. They don't have mountains to use, the states are larger than in the East (meaning fewer section multipliers), and the centers of population are widely scattered. However, they need not drop out of the game yet. By emphasizing operation on six meters, they can make use of tropospheric scatter, a special kind of VHF propagation where the range goes far beyond line of sight. A strong signal with the antennas at the correct height for a scatter "take-off angle" allows W8DJY to work a lot of different stations on six meters and, more importantly, get section multipliers from four different directions.

By now you are probably asking yourself: "Is W8DJY a winner?" The answer is a relative one. The ops were elated to place in the top ten scores for the September, 1979, VHF QSO party. This came only three years after W8DJY started to take VHF contesting seriously. Each contest means improvements in scores and techniques. Always building and scheming, the W8DJY success is based on a nucleus of about half a dozen individuals.

W1FC—The Big Gun Station

While the men of W8DJY set their sights on a record division score, the members of the Barnstormer Amateur Radio Club aim at breaking the existing world's record, one that they set only a year before. "Big gun" is an understatement when it comes to describing the Barnstormer operation under the call of W1FC. Each June, the ops attack Pack Monadnock, southern New Hampshire's tallest drive-up mountain. Numbering more than 40 strong, they convert the normally tranquil Miller State Park into a beehive of activity.

Families planning a quiet picnic on those two sunny weekend days in June came in for a surprise. Everywhere one looked there were towers being planted and tangles of wire and tubing that resembled antennas; everything was being done with an urgency rarely found on mountaintops.

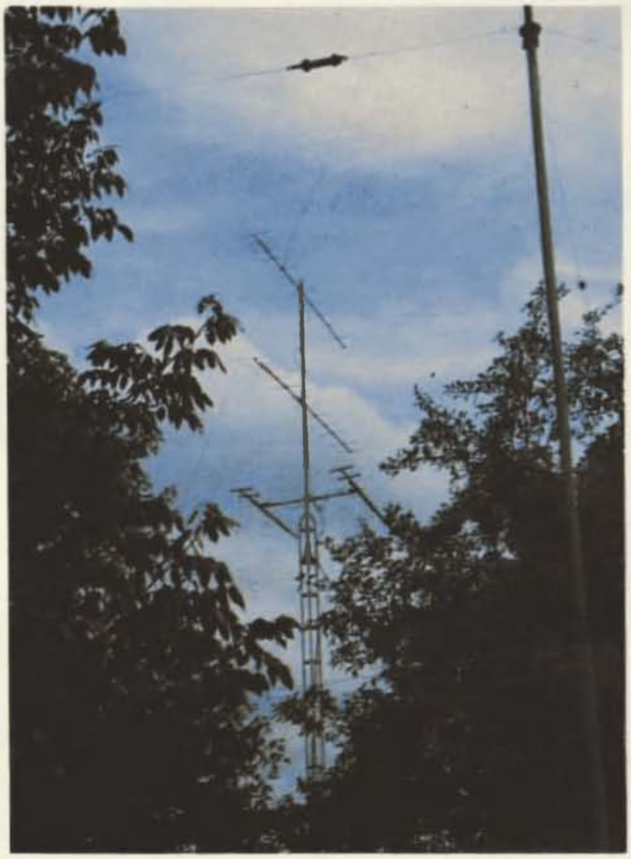
Off to the side, Fred Collins, one of the main forces behind W1FC, stood calmly watching the erection of six independent stations each with its own antennas, rigs, and shelter. The stations were tied together not only by a desire to win, but also with a common electrical system and dial telephone network installed just for this weekend.

Cherry Pickers and Microwaves

Fred explained that the Barnstormers had been active in VHF contesting since the mid-1950s. Their more than 20 years of experience

Microwave operation from Pack Monadnock means excellent range and great views of the New Hampshire countryside for the W1FC crew.

Up, up, and away. The cherry picker is pressed into service so that the microwave signals can clear the trees easily in all directions.



Visitors to Miller State Park shook their heads in disbelief as they saw erected arrays like this one for two meters.

had been molded into a comprehensive organization dedicated to winning the June VHF QSO Party. Each band was under the direction of a manager who oversaw the installation and then the operation. Other experts handled the liaison with park officials, telephone and power companies, and the very essential food tent.

The 1980 June contest was the Barnstormers' first effort involving a cherry picker snorkel truck. Arrays for 2 meters, 220, and 432 went up in minutes on 20- and 30-foot towers guyed to nearby rocks with packing twine. The cherry picker, borrowed from a Boston area firm for the weekend, was just one example of how the W1FC gang makes the most of available resources.

By 1978, the W1FC contesters had developed excellent stations and operating techniques for the frequencies below 2 gigahertz. In 1979, a year of hard work paid off when they were able to operate on 2.3, 3.4, 5.7, and 10 GHz. One setup remained on Pack Monadnock while others were sent traveling to nearby states so that five sections could be worked on each of the new bands. The efforts paid off. The score was a record one that outdistanced the nearest competitor by more than 20,000 points.

A rules change made the 1980 contest even more challenging. This year they needed five complete microwave stations, each capable of operating on four bands. The collection of gear required was probably the largest amount of amateur microwave equipment ever assembled in this country. Once again, the resources and skills of the Barnstormers prevailed.

At the last-minute strategy session, there was talk of setting another record—one that nobody could break. The friendly euphoria of setting up was gone. The mood grew serious. "Keep your stations transmitting all the time, always turning the antennas!" The operators on the populated six- and two-meter bands were expected to keep the rate up. Suddenly, the pep talk was over and it was time to begin.

The spirit of W1FC was expressed by one operator who gazed proudly at a remote 1296 rig which he had helped to build. He said that last year they made 19 contacts on 1296 and that this year the goal was 25. I noticed that he had a six-pack in hand as he headed for the shack (which was someone's van the rest of the year). It would be a long night of calling, hoping, and thinking about what could be done for 1981.

Conclusion

On the low bands, cynics abound. They claim amateur radio is dead. It is said that we are guilty of being appliance operators, that the gentlemen's camaraderie is long gone, and even that the fun has left ham radio. Visit or talk to a VHF contester, he or she will tell you a far different story. ■

Sell 'Em with Slides

—A/V shows can fire club enthusiasm

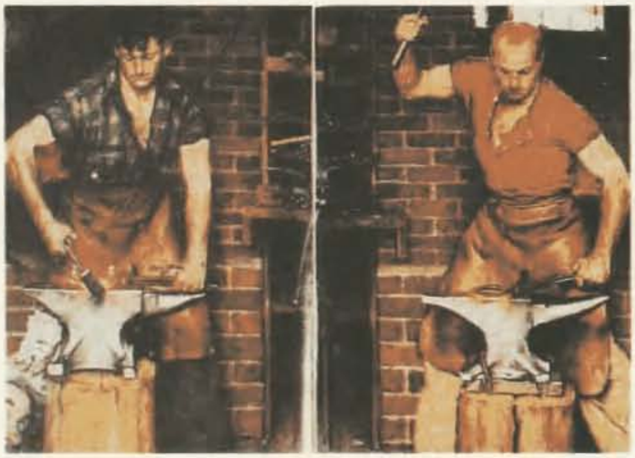
"Let's put on our thinking caps and produce one hamfest that will really draw a crowd."

Matt Beha N8BPI
3752 Lane Court
St. Joseph MI 49085

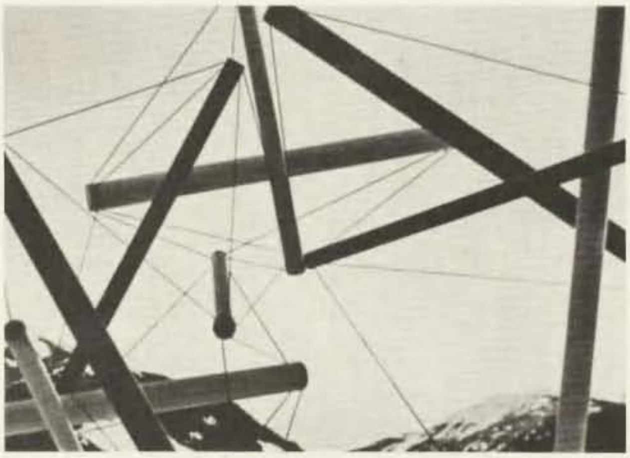
When I was named chairman of the Blossomland Amateur Radio Association's 1980 hamfest, I had some new ideas. To make sure they would be accepted, to thwart the potential wet-blanket-thrower every group seems to have, and to light a fire of enthusiasm under our club, I decided to promote our hamfest with a big kickoff.

For background, let me explain that the hamfest the year before had been held in an unheated county fair exhibition hall on a cold October Sunday. More than a few of us went home with the sniffles. That, plus the fact that I wanted to produce a little more than a flea market, prompted me to look for a new and better site for our 1980 function.

The logical site, in my estimation, was Lake Michigan College's new Community Center near Benton



"How about a brass-pounder's contest?"



"Let's let the club experts give a lecture on antenna design."

"It's conveniently located to Chicago, South Bend, and Kalamazoo . . ."

"The place we should hold our 1980 Blossomland ARA Hamfest is the beautiful new Lake Michigan College Community Center."

Harbor, Michigan. Not only did it offer us the chance to double our floor space, have heat or air conditioning as needed, and have separate areas for tech sessions, movies, and flea market, but also its location just one mile off exit 30 of I-94 was more convenient than last year's.

I checked with the College. Would the Community Center be available for Sunday, October 5, the traditional day for the Blossomland Fest? A sigh of relief—Linda Castle, the director of the Center, said the date was still available. Next crucial question: How much would it cost? Just as I had suspected—about double what we had spent the previous year. That would require a little selling job to the club members.

First, I gathered a nucleus of club members I knew would support me, and we arranged for a tour of the Community Center to make sure it would meet our needs. On February 18, Jon WAØTAQ, Matt WA3LOP, Craig WB8VKA, Al W8LRM, and I were given a tour by Mrs. Castle. Fantastic! The center had: more than twice the space of our previous site; plenty of electrical outlets; handy access for our dealers and distributors to unload and load large quantities of ham gear; a catering service to provide food; and our choice of one, two, or three beautifully carpeted lecture rooms in addition to the flea market area. They even had 2,500 paved parking spaces.

So far, so good. Now to prepare a presentation for the next club meeting to forestall any negative ideas . . . and to generate enthusiasm for our 1980 hamfest.

I decided an A/V (audio/video) show with lively music and a script supported by slides would sell the idea to the club. First I wrote the script, beginning with the negative aspects of our previous site, moving on to possible plans for a bigger hamfest with technical sessions, and then presenting the Lake Michigan College facility as the perfect setting for our 1980 "Blossomland Blast," as I decided to call it.

Once I had written and rewritten the script, I jotted down some notes on possible slides to illustrate my points. Armed with script and a list of pictures, I took off down Washington Avenue to the Lincoln Township Library. I made a beeline to the photography section and selected a dozen or so books of photographic art pictures. I set up camp at a table and flipped through each book, page by page. When I spotted a picture I thought would illustrate a point (sometimes humorous, sometimes not), I would put that book aside. Within two hours I had the pictures I wanted and checked the books out.

"That's the plan for the 1980 Blossomland Blast—the biggest and best hamfest yet in southwestern Michigan!"

I was spared the task of shooting the slides myself. We're privileged to have a professional photographer in our club, whose studio shoots the ham gear pictures for the Heathkit® catalog. Jim KA8GIX volunteered to make the slides for me and did a super job.

Naturally, not all the slides I needed were to be found in books. I wanted supporting proof that our club could afford the higher rent. First, I did a survey of hamfest ads for amateur magazines: I discovered that our 1979 ticket prices had been way below average. If we raised prices just to the average and maintained attendance, we would be able to cover our expenses. And with a little added promotion, we would be able to show enough profit to keep our repeater rig going for another year, which was the original intent of the hamfest.

I made up some charts, a rough sketch of the Community Center's floor plan, and a map showing access. Another club member, Floyd K8ZLO, arranged to have some beautiful graph-

ics done, and those also became slides.

When I got the slides, I put them in the projector and started a tape. The music I had selected for background music was Billy Joel's "Root Beer Rag," a very lively instrumental that I knew would generate enthusiasm. Then I ran through the slides and script, timing them to the music, changing slide sequence here and there, until I had the time down pat.

I practiced a number of times before the meeting to make sure I knew when to hit the slide changes (wishing I had the bucks to have it pulse-controlled). On meeting night, our club president, Larry W5VUF, arranged for me to have the last spot on the business agenda so that I could talk to potential volunteers for hamfest duty while we broke for refreshments.

My spot came, the lights went out, and I launched into a short, snappy six-minute presentation with the script I had memorized, the music, and the slides.

When the lights came on, there was a fair round of applause. Co-chairman Jon WAØTAQ and I passed out a prepared sheet to each member. On it I had written up a sample program for our planned hamfest—an ARRL movie (if I could get it), a slide-show tour of the Heathkit factory (if I could shoot it), an XYL program, lectures, and demonstrations by experts from our club or the area. At the bottom of the sheet I had typed out a list of requests—typing help, volunteers to take posters and flyers to other fests, volunteers to make signs, give ideas, etc. I put my name and address at the bottom of the sheet.

The enthusiasm was great. If there had been any wet blankets waiting to be tossed because of the high rent (or who knows what), they weren't in evidence when the membership voted to expend the necessary funds to hold our October 5 Blossomland Blast at Lake Michigan College. It was unanimous.

I enjoyed the slide show so much that I've since done another on our club's first transmitter hunt, using the folksong "The Fox" for background music. I'm going to do another on our Field Day activities for another club meeting. Slide shows are fun to do, and they can add a new dimension to your club's meetings. ■

Slide	Narration
Churchill holding up two fingers in Victory sign	In the past, the Blossomland Amateur Radio Association has held *two* hamfests each year.
Modern art skeleton	They were pretty bare-bones affairs—basically flea markets where everybody came...
Modern art junk pile	to look at everybody else's used gear, kick the tires, and then go home.
Crowd of 1910 kids	This year let's really draw a crowd to our Blossomland Hamfest...
Kid with weird hat	let's put on our thinking caps and produce one hamfest that will...
Large crowd with motorcycle cops	really draw a crowd.
Girl watching puppet show	Let's really put on a show...
Man with huge 5¢ sign	and give ticket buyers their money's worth!
Squiggly art work	We could give demonstrations on slow-scan TV.
Old-timer at typewriter	Or show people how RTTY works.
Two blacksmiths	How about a brass-pounder's contest?
Boat and flooded sign	Hutch WB8WLS could give a presentation on emergency operations...
1920's rig	Neil WD8MAW, would you like to head a program on contest operations?
Rube Goldberg contraption	We could have a slide and sound tour of the Heathkit factory.
Modern art spider web	Let's let the club experts give a lecture on antenna design.
1910 school kids	We'll send our ticket buyers home a little wiser than they came, with a program like this.
"Etc." cartoon	Those are just a few ideas. With the talent we have in this club, there's even more that we can do.
Packed football stadium	A hamfest like this will draw a crowd, so we'll need a place to put them.
Nutty tractor driver	The place I'm thinking of has plenty of free, paved parking—2,500 spaces, in fact!
Men with electronic gizmo	It's a place that will attract a lot of dealers and distributors to display their wares.
Kid with hamburger stuffed in mouth	The place I have in mind even has a food catering service...
Crazy sheriff	and its own security force.
Map with distances	It's conveniently located to Chicago, South Bend, and Kalamazoo.
Lake Michigan College Community Center	The place we should hold our 1980 Blossomland ARA Hamfest is the beautiful new Lake Michigan College Community Center.
Floor plan	14,400 square feet of space, more than double what we have had in the past—with separate areas for movies and lectures. All the space we need to put on a first-class hamfest!
Baby crying	Now you're asking, "How much is this going to cost?"
Less-than-$650 slide	Including tables, chairs, setup and security, less than $650. But you're asking, "Where will we get the money?" Take a look at this...
Chart—1979 hamfests	a survey of 1979 hamfests shows that our ticket prices were well below average.
Chart—1979 sales, projected sales	Last year we brought in $1,266.00 in ticket and flea market sales. If we have the same attendance in 1980 and raise our prices to the average (and that's only the 1979 average), we'll bring in $1,817, more than enough to meet the increased expenses. Of course, if we put on a great fest and promote it, we could double attendance.
Chart—promotion	How can we promote our hamfest? First, with a mailing to last year's ticket buyers; second, a mailing especially for clubs; third, ham magazine ads, press releases, and photos to area newspapers; next, television and radio talk shows. What about a QSO party to promote our fest? Later I'll be giving you flyers to send out with your QSL cards. We'll have flyers to give dealers who will be attending. Finally, you'll receive mike-side fact sheets you can use to promote our hamfest when you make a contact.
Club's Bumblebee with Blossomland Blast logo	That's the plan for the 1980 Blossomland Blast—the biggest and best hamfest yet in southwestern Michigan! See you on Sunday, October 5.

The Power Waster

—adjustable electronic load for power supply testing

John Roos K6IQL
953 Valley High
Thousand Oaks CA 91360

Testing of bench power supplies, batteries, voltage regulators, or current limiters often requires application of an adjustable load to the circuit. After years of connecting haywire combinations of resistors together to test various power supplies, I determined that a really high-power adjustable electronic load would be a welcome addition to my test equipment. In short order the Power Waster was created, and during some three years it has proven most useful.

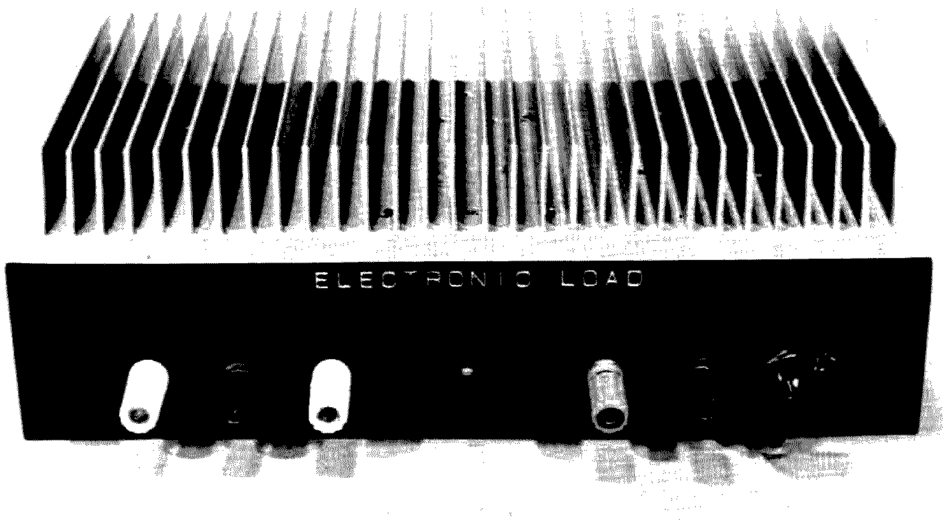

Photo A. *The Power Waster. This electronic load is adjustable from 0 to 10 A and can dissipate up to 300 Watts. The unit is built upon a piece of heat-sink extrusion and has both reverse polarity and thermal overload protection.*

The load described in this article will handle the majority of amateur radio and microprocessor power supply tests. In addition, it has a number of other uses, such as constant-current battery charging.

Current drawn by the load is adjustable from 0 to 10 Amperes. Input voltages up to 30 volts are permitted at full current; that's 300 Watts dissipation! Heat sinking of the pass transistors is sufficient to permit 300-Watt operation for about ten minutes, at which point a thermal protection switch shuts the current off.

At 100 Watts dissipation the heat sink is adequate for indefinite operation. By directing a small blower at the heat sink, I have run the load at 300 Watts for hours without difficulty.

Since I desired essentially self-contained operation, I included a small supply in the unit to bias the load transistors. Current is controlled by means of a front panel pot, and reverse polarity protection is included. A front-panel LED indicates operation of thermal shutdown circuitry. I took advantage of extra heat sink area to add two 8-Ohm, 50-Watt resistors. These are used for testing audio amplifiers or to increase the dissipation capability of the Power Waster circuit.

Circuit Operation

The simplified schematics in Fig. 1 are useful in understanding how the circuit operates. Commercial load boxes use current sensing and feedback to set the load current. My approach is simpler and uses the constant-current collector load-line characteristic of all bipolar transistors.

Fig. 1 shows the basic idea. The base of Q1 is biased at several volts from voltage source V1. The collector supply (V2) is greater than V1 by at least 1 volt. The voltage at the emitter of Q1 is one diode drop (0.7 V) below the base voltage, and the circuit is essentially an emitter follower. Emitter current is set by dividing the emitter voltage by R1. As R1 is decreased, the emitter current increases.

The collector current for any transistor is simply alpha (the common-base current gain) times the emitter current. As alpha is essentially equal to 1 for any modern transistor, we see that setting the emitter current also sets the collector current. And this is the point; the collector current is determined only by the emitter current. Collector voltage has almost no effect on the collector current, provided the transistor is kept from saturation or breakdown. Saturation occurs if the collector voltage becomes less than the base voltage. Breakdown will occur if any excessive voltage is applied.

The constant-current collector load line is a useful property. If the voltage across R1 is small compared to the collector supply, a lot of power can be controlled and will be quite independent of the collector supply voltage. If a relatively low base-bias voltage is used, most of the power will be dissipated in the transistor and relatively little in R1.

As useful as this circuit is, there are some disadvantages. The main problem is that R1 must be a variable resistor capable of handling the entire load current. In a practical circuit, this becomes a 0.2-Ohm pot rated for 10 Amperes, which is an expensive item.

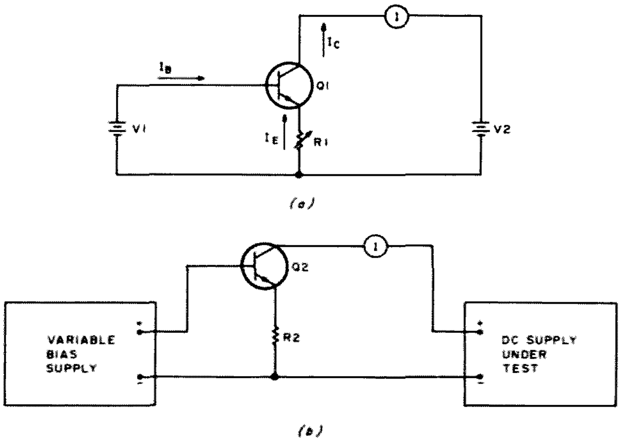

Fig. 1. Constant-current bias circuits. (a) A transistor with fixed base voltage. Collector current is set by emitter resistor. (b) Basic circuit of the electronic load. Emitter resistor is fixed, and both emitter and collector current are controlled with base-bias supply voltage.

By arranging the circuit as indicated in Fig. 1(b), things become a bit easier. Resistor R2 is a fixed high-power resistor. The base supply is made variable. Since the circuit is essentially an emitter follower, the emitter voltage follows the base voltage. Increasing the base bias increases the emitter voltage and the emitter current through R2. This increases the collector current to the desired value.

Within limitations, the collector current is set solely by the base-bias voltage and the value of R2. These limitations are: The collector supply must be at least one volt more than the max-

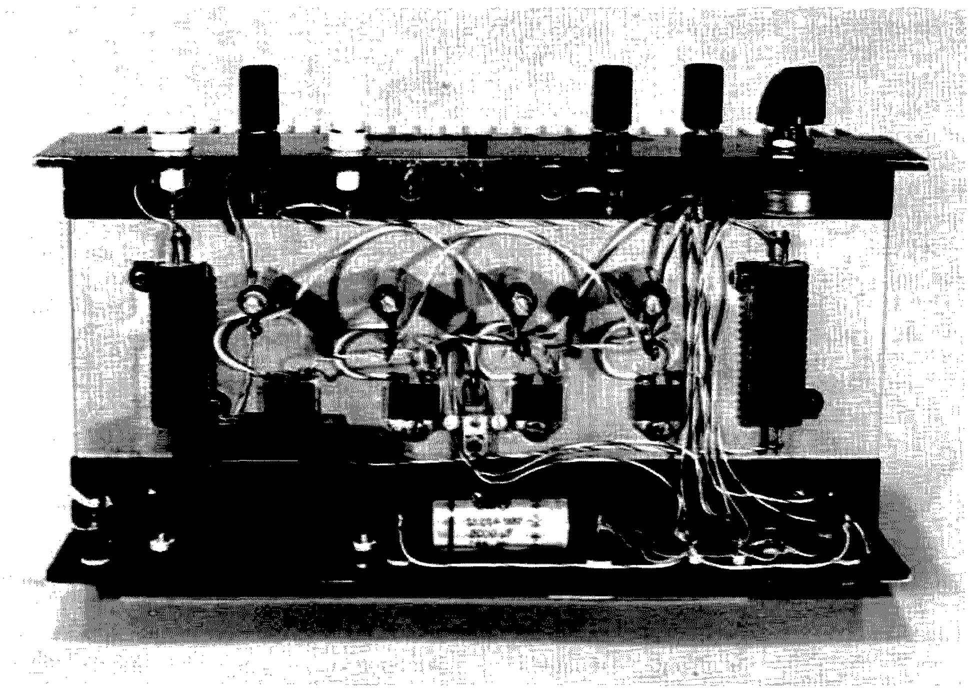

Photo B. Interior view of the Power Waster. Four TIP 35C load transistors are mounted to the heat sink. The thermal switch is located between the two center transistors. A U-shaped chassis is formed from the heat sink and two pieces of aluminum angle stock.

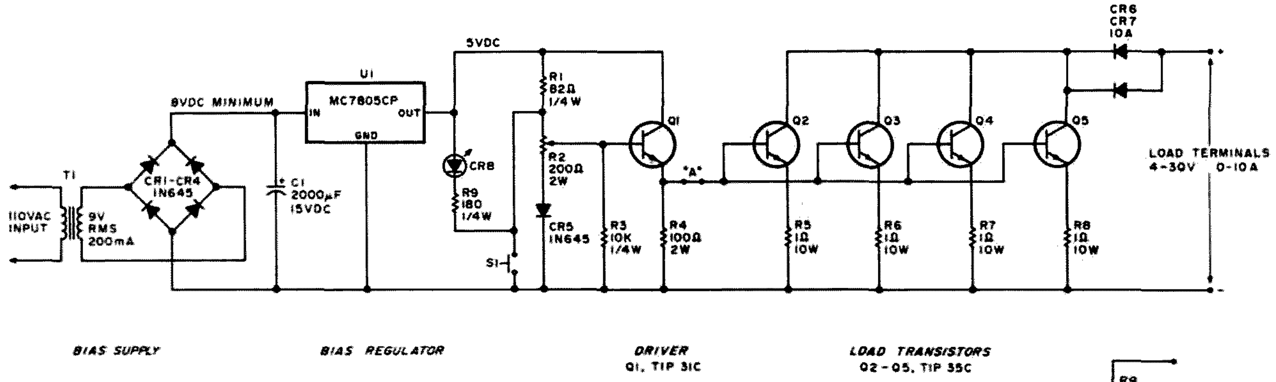

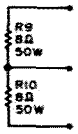

Fig. 2. Schematic of the Power Waster electronic load. S1 is a 75° C NO thermal switch. S1 is in thermal contact with the heat sink. The collectors of Q2-Q5 are connected directly to the sink. LED CR8 indicates thermal shutdown. Jumper at point A is opened in test.

imum base-bias voltage, and must be less than the transistor breakdown voltage for the current drawn.

In addition, it is assumed that the base-bias supply is capable of supplying increasing current to the transistor base as the collector current increases. The base current will be the transistor collector current divided by beta, the common emitter current gain. Beta will vary from 10-50 for practical power transistors.

To convert these ideas into the final design, I had only to add a base-bias supply, circuit overload, reverse polarity protection, and to increase the number of load transistors to handle the required power. The result is shown in the schematic diagram.

Power is dissipated in the pass element (consisting of Q2, Q3, Q4, and Q5 connected in parallel). Four TIP 35C transistors are used in order to safely handle the 10-Ampere maximum load current. Each pass transistor has a 1-Ohm resistor in the emitter which corresponds to R2 of Fig. 1. In addition to setting the collector current for a given base voltage, these resistors also equalize the load distribution between the four pass transistors and help to keep the load current constant as the transistor temperature increases.

Variable base voltage for the load transistors is obtained from emitter follower Q1 which operates from a 5-volt regulated supply. This circuit consists of transformer T1, the bridge rectifier (CR1-CR4), C1, and an MC7805CP three-terminal regulator chip (U1).

The base of emitter follower Q1 is connected to a variable voltage divider consisting of R1, the pot (R2), and diode CR5. R1 and CR5 limit the driver base voltage range to approximately 0.8 to 4 volts. An additional 0.8-volt offset in the base-emitter junction of Q1 results in a driver output voltage range of 0 to 3.2 volts. Restricting the drive voltage to 3.2 V sets the maximum current the load will draw to 10 A. CR5 was included to compensate for the change in the base-to-emitter threshold voltage of Q1 as the temperature changes. In use, this simple bias supply has proven completely adequate. There is very little drift in load current as the temperature increases.

Some additional features are worthy of mention. Diodes CR6 and CR7 provide reverse polarity protection. A thermal switch (S1) shorts the base-bias supply and turns the current off if the heat-sink temperature becomes excessive. An over-temperature shutdown is indicated by illumination of the LED (CR8).

R4 provides a return path to the transistor emitters for collector-to-base leakage current. This assures that they will actually turn off when the base-bias voltage is removed. R3 is there for safety in case the wiper of R2 opens. This is the usual method of failure for pots. Inclusion of R3 assures a path from base to emitter for the collector-to-base leakage current of Q1. In its absence, failure of R2 could cause the load to pull more than 10 A and damage something. With R3 included, the circuit just shuts off.

A series-connected pair of 8-Ohm, 50-Watt resistors is also mounted on the heat sink of the electronic load. These are provided to increase the dissipation capability of the unit and, in addition, are handy for testing audio amplifiers.

Power Rating

While the nominal input capability of the Power Waster is 10 A at up to 30 V, it may be operated at higher voltages if the proper conditions for safe operation are understood. In this section, I will explain how the nominal power rating is derived.

All high-power transistors have a "safe area" of operation, in which no damage will occur. Fig. 3 is a safe-area curve for a single TIP 35C. This is a plot of maximum-permitted collector current as a function of collector voltage. Operation at any point in the region below and to the left of the curve will not damage the transistor. Combinations of voltage and current above and to the right of the curve will certainly destroy the transistor.

It is interesting that the power dissipation capability is not constant. At a Vce of 5 V, a current of 25 A is permitted. That's 125 Watts. But if the voltage is increased to 50 volts, only 1 Ampere is allowed, providing a dissipation capability of only 50 Watts! The successful designer of high-power transistor circuits stares long and hard at the safe area curves before picking a final configuration!

When I designed the Power Waster, I tried to be conservative so that it could really take abuse without failure. Thus, four TIP 35C transistors were used. In Fig. 4, the composite safe-area curve for the four devices in parallel is shown. This is Curve B. Curve A indicates the "rated" operating envelope for the Power Waster. Only at the 10 A and 30 V point does the "rating" curve approach the safe-area curve.

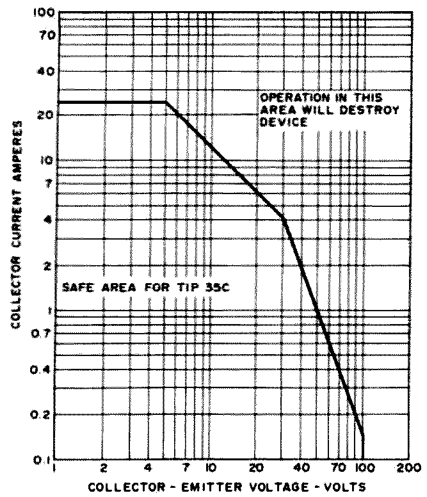

Fig. 3. Safe-area curve for TIP 35C. Safe operation is limited to the area below and to the left of the curve. Operation beyond the safe area will destroy the transistor.

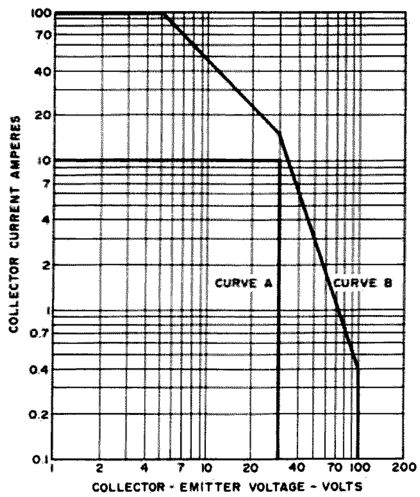

Fig. 4. Operating areas for the electronic load: Curve A indicates the rated operating area for the load. Curve B shows the composite safe area of the four TIP 35C transistors used as the load element. The rated operating area (Curve A) is well inside of the safe area.

At all other combinations of current and voltage, the power dissipation is comfortably inside of curve B.

This conservative design assures that the unit will never fail as long as the 10 A and 30 V maximums are observed.

Construction

Construction of the electronic load can take almost any form because of the non-critical nature of the circuit. In most cases, the shape of the heat sink will determine the final configuration. In order to dissipate 300 Watts, a sink having a thermal resistance of 0.1° C per Watt is required. This is a truly massive piece of metal. I elected to depend upon thermal inertia to permit short tests of up to ten minutes duration and to let the thermal cutout act if things got too hot. Continuous operation is obtained by directing a small blower at the heat sink.

I used a 5″×11″ piece of heat-sink extrusion having 32 one-inch-high fins as a chassis. To this I fastened a pair of 0.75″×2″ pieces of angle to form a U-shaped chassis with the fins on top. All parts are mounted on the underside of the extrusion, and the front and rear panels are formed by the pieces of angle. Vertical fins are more efficient, of course, but since a cooling fan is required to obtain the full power rating, this arrangement is quite convenient.

Parts located on the front panel include the three binding posts for the 8-Ohm resistors (R9 and R10). These are at the left end of the panel. Next is the LED over-temperature indicator. Adjacent to the LED are the input terminals for the electronic load. The load current adjustment pot, R2, is on the extreme right end of the panel.

Mounted directly to the underside of the heat sink are the two 8-Ohm resistors, the four emitter resistors for the load transistors, and transistors Q2 through Q5. The thermal switch (S1) is located in the center of the sink. Two reverse-polarity protection diodes (CR6 and CR7) are also mounted directly onto the heat sink near the center of the front panel. All parts are mounted to the sink by threaded holes tapped directly into the extrusion. The cathode ends of CR6 and CR7 are connected to the sink via threaded mounting holes. In the same way, the collectors of Q2-Q5 are screwed directly to the sink. Thus, the connection from the polarity protection diodes to the transistor collectors is via the heat sink itself. Fastening the transistors to the sink without insulating wafers puts the entire chassis at the potential of the positive supply input.

Normally, I would have insulated the transistor collectors from the sink but there is a good reason for not doing so. The thermal impedance of the transistor junction to case is 1° C per Watt. Most insulating wafers have a thermal resistance of at least 0.5° C per Watt. If a wafer were used, the resistances are summed to yield a thermal resistance of 1.5° C per Watt. The junction temperature would rise by fifty percent! Instead, I elected to have the positive supply input on the sink and to exercise caution in using the unit. The low voltages involved certainly pose no shock hazard.

On the rear panel are located: the power transformer, bridge rectifier, filter capacitor, 5-volt regulator, and the driver transistor (Q1). The transformer is located at the left end of the rear panel. The filter capacitor is in the center of the panel as is the bridge rectifier, which is hidden by the capacitor in the photograph. Adjacent to the filter capacitor is the 5-V regulator and the driver circuit components. U1 and Q1 are both fastened to the rear panel for cooling. All small parts such as resistors, capacitors, and diodes are mounted with push-in Teflon terminals. Threaded standoffs are used for the larger components.

Not everyone who wishes to build this circuit will be able to find a heat sink similar to the one I used. One approach is to use four smaller sinks and to mount a load transistor on each. A suitable configuation would use four Wakefield Engineering type NC-423 heat sinks. Individually, these units have a thermal resistance of 0.8° C per Watt so the resistance of the combination would be 0.2° C per Watt. Such an arrangement would permit inputs of about 150 Watts without forced-air cooling.

Testing

A few simple tests prior to using the load will prevent damage to it, or to the circuit being tested. First, break the circuit between

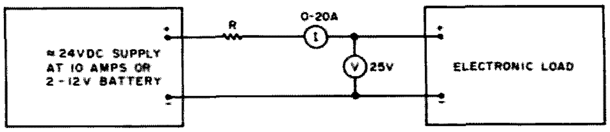

Fig. 5. Testing the Power Waster. A high-current supply such as a pair of 12-V batteries is connected to the load via current-limiting resistor R. The resistor should be chosen to limit the current to a few Amperes for the initial tests.

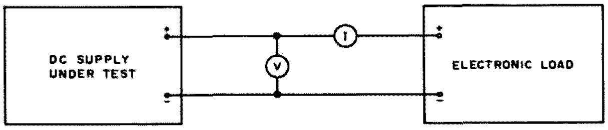

Fig. 6. Using the load to evaluate a power supply. Increasing current is drawn from the supply, and the regulator performance is measured. The load also may be used to ensure proper current-limiter operation.

the driver transistor (Q1) and the load transistors (Q2 through Q5), at point A in Fig. 2. Apply 110 V ac to the power transformer and verify that the voltage is variable from about 0 to 3.5 V as R2 is rotated. Zero volts should occur at the extreme counterclockwise position of R2. This is the zero current setting.

Reconnect the circuit at point A. Then arrange a high-current test setup similar to Fig. 5. Resistor R is chosen to limit the current to 3 or 4 A under short-circuit conditions. Two automobile headlamps in series may be used for this resistor. Set the current control pot (R2) at minimum (CCW position) and turn on the supply and the bias supply in the Power Waster.

Increase the current setting until 2 A is drawn by the load. Measure the voltage drop across R5 through R8 and assure yourself that the voltages are about equal. About 0.5 V should appear across each resistor for a 2-A load. If no voltage appears, then the associated transistor is not drawing any current.

Next, advance the current control. The load current should increase smoothly until the voltage at the load input terminals drops well below 5 V. At this point the load transistors will saturate and the current will be set by resistor R.

The next step is to test the current-limiting feature to verify that the load current is limited to about 10 A. Reduce R in value so that for the supply voltage present under load, about 15 A may be drawn. Again increase the load current from zero with R2. The load should current limit at 9 to 11 A if the same parts values were used.

If all of the above tests were successful, the electronic load is ready for use.

Applications

My purpose in building the electronic load was to enable rapid test of power-supply circuits. The 10-A and 30-V input capability will suffice for almost the entire range of solid-state supplies found in amateur equipment. After I built the load, a number of other applications surfaced. Some of these are worthy of mention.

The performance of a voltage regulator is easily plotted by using the load, connected as indicated by Fig. 6. The regulator is connected to the load via an ammeter. A voltmeter is connected across the output of the supply. By increasing the load current and noting the meter reading, the internal resistance of the regulator may be found, and the percent regulation as a function of load determined. If the supply has a current limiter, the current-limiting point may be found by slowly increasing the load current until the voltage drops. The smooth control of current afforded by the electronic load makes these tests easy.

At times it is desirable to know if a surplus transformer of questionable ancestry can meet a given requirement. Of particular concern is the "overhead" voltage requirement. This is the input voltage required to maintain a regulator in operation (at full load) subtracted from the output voltage.

Typical three-terminal regulators require a 3-volt overhead to function properly. If all circuit parameters are known, it is easy to determine if a certain transformer, rectifier, and filter capacitor will work. If junkbox parts are used, the calculation is often difficult or impossible. It takes only a few minutes to connect up the unregulated supply parts and apply the expected load current using the Power Waster. The unregulated voltage and ripple may be measured, and the suitability of the components determined.

Battery charging is another application. All batteries must be charged from a current source so the charging current is held constant as the battery terminal voltage increases. To use the load as a battery charger, simply connect it in series with a source having a voltage at least 4 V greater than the full-charge voltage of the battery. Then place the combination in series with the battery and dial up the desired charging current.

One final application is protection of high-power transistors during tune-up. The electronic load is placed in series with the supply and programmed for the maximum current that you feel is safe for the amplifier under test. At currents less than the setting, the load saturates and the voltage drop across it is quite small. This is especially true at the lower currents.

Should the amplifier try to draw excessive current, the maximum will be limited to the set value. Response is very rapid. Current limiting occurs in about a microsecond and in the case, is much faster than a normal power-supply current limiter. So effective is this method of protection that I have built it into several solid-state transmitters.

Conclusion

Electronic loads are common in professional labs where power supplies are developed. Many are built from scratch, but also they are sold by commercial test equipment manufacturers. Such devices permit evaluation of supplies prior to connecting them to their intended (and often very expensive) loads.

In writing this article, I have attempted to describe the application and operation of a little-known but very useful piece of test equipment. While my Power Waster is certainly austere as compared with the professional units, it will definitely do the job. The basic design could be modified to include meters and an internal cooling fan. If this were done, the complete unit could be packaged in a well-ventilated box where the heat sinks would be better protected from accidental contact.

I welcome comments or questions from anyone wishing to either duplicate or modify the circuit.■

QRZ Sunshine

—building solar-powered repeaters

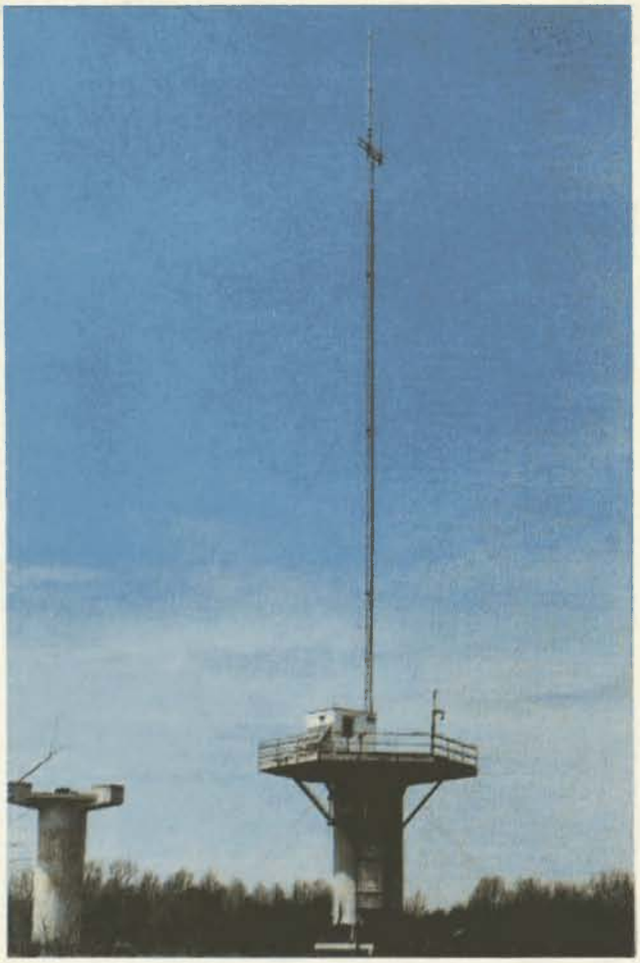

Photo A. AARC repeater. Photovoltaic array is visible on the left side of the shack at the base of the tower.

A totally solar-powered repeater recently went on the air in Maryland. On March 15, 1980, the Anne Arundel Radio Club (AARC) switched from 110 V ac to sunshine to power a new 220-MHz repeater recently installed at the AARC site in Davidsonville, Maryland, near Annapolis. This unique microprocessor-controlled repeater will itself be the topic of a forthcoming article, as soon as its builders get around to writing it up.

The Site

The repeater is located at an abandoned Nike missile site which was provided to AARC by the local Davidsonville Family Recreation Center. A ready-made clubhouse and a 10m-high structure (former radar pedestal) at one of the highest points in the area offer an ideal location for this active and public-service-oriented amateur radio club. A 3m × 3m repeater shack was built atop the pedestal and a 40m antenna tower was added. At the present time, the club operates both a 2-meter repeater (147.105/147.705) and the 220-MHz repeater (223.88/222.28) and is planning to install a 430-MHz ATV repeater in the near future.

The repeaters offer reliable and convenient communications within the Washington, Baltimore, Annapolis, and central Chesapeake Bay area. Many of the club members are avid boaters, and during the boating season maintain a weekend weather net which also provides real-time information to the National Weather Service about the rapidly changing weather conditions on the Bay.

Photovoltaics

Photovoltaic (PV) panels, which convert sunlight into electricity, were provided by the Department of Energy in response to a request from the AARC in December, 1979. The panels were shipped to the club on loan from the Jet Propulsion Lab in Pasadena, California, in late February, 1980. (Who says government can't react quickly?) The PVs were part of a DoE research-and-development program to improve PV technology and reduce production costs.

he PV array consists of 14 ıdividual panels, made by ensor Technology Corp., ach about .3m × .6m ×)3m, attached to a 1.3m ‹ 2.3m frame made of ressure-treated lumber. he frame is fastened irectly to the south side of ne repeater shack at a 53° ngle (from the horizontal) /hich will optimize electric eneration during the /inter. Each panel is rated bout 18 V at 0.55 A, and vith the panels connected ı parallel, the array was ex- ıected to produce about 18 ' at 8 A (at noon on a sunny lay).

Output voltage for this ›articular panel is some- vhat temperature-sensitive, ›ut at a constant tempera- ure, it is fairly independent ›f current draw up to the ated current, whereafter it alls very rapidly to a max- mum short-circuit value of).62 A per panel. A check of ›ur 14-panel array showed ı maximum short-circuit :urrent of 8.7 A. Even on a /ery cloudy day, the array ›roduces about 0.5 A, vhich is more than ade- ıuate to provide the repeat- ›r's standby current draw of ıround 300 mA.

The 14-panel array is ex- ›ected to produce almost 400 Watt-hours during an ıverage December day, vhile in June it should be almost twice that amount. The array converts only about 6 percent of the sunlight falling on it into electric energy (actually the individual cells are about 10-percent efficient, but there is considerable open area between each cell in the panel). This should be sufficient power to run the repeater without auxiliary power, year-round, hopefully for the next 10 years, the panel service-life design goal.

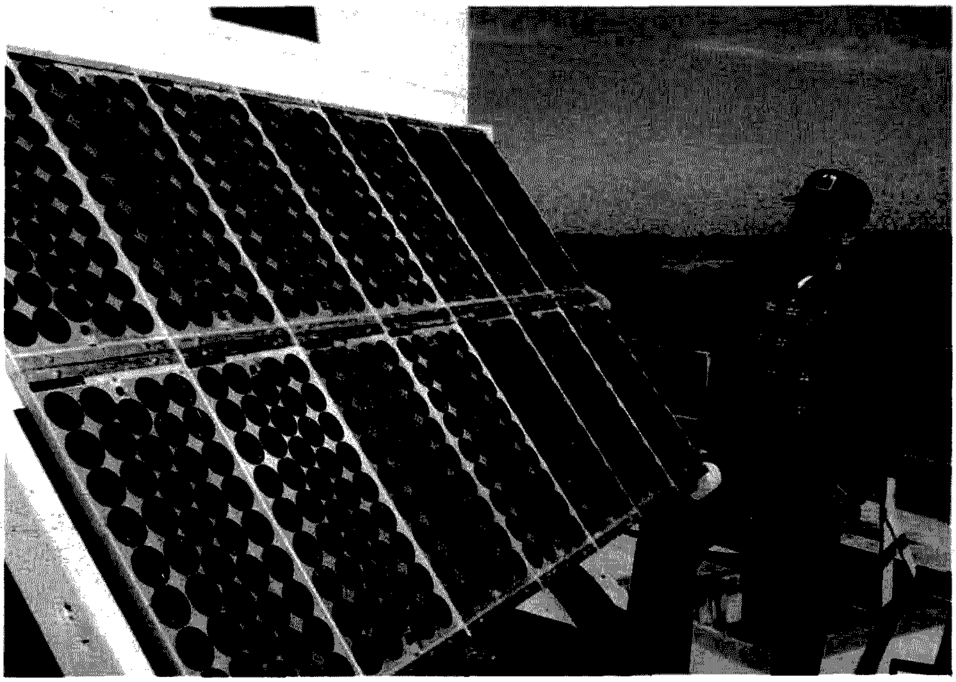

Photo B. Photovoltaic array. Frank Troutman WB3CLF helped install the array on the side of the shack.

Power Conditioning and Storage

Since the repeater requires 12 V dc around-the-clock, and the array produces 18 to 25+ V dc for only part of the 24-hour cycle, some sort of power-conditioning and energy-storage system is needed. A simple system was designed to provide high reliability and efficiency at a low cost. It consists of a 16 V (13-cell, 20-Ah) primary nicad battery storage module, charged directly by the PV array through an overcharge protector. A 12-volt (60-Ah) secondary-storage auto battery is diode-isolated from, and trickle-charged by, the nicad battery.

A clock attached to the transmitter measured an average daily transmit time of about two hours. At a transmit current of 3 A, the average daily transmit power is 6 Ah, and at the .3 A standby level, another 7 Ah is consumed. Thus, the total average daily power consumption is around 13 Ah at 12 V dc (156 Wh/day). While the array output of 400 Wh would appear to be more than sufficient to power the repeater, there are major energy losses built into the system which must be taken into account.

Batteries are less than 100-percent efficient, and the trickle-charge circuit dissipates an appreciable amount of energy. If we assume an average battery efficiency of 80 percent and a trickle-charge rate of 700 mA, we end up with only about 170 Wh being delivered to the repeater, which just slightly exceeds its anticipated demand of 156 Wh/day. It must be remembered that this was calculated for the worst part of the year (December), and in any event, the fully-charged 12-V battery should have enough capacity to run the repeater for at least four consecutive cloudy days.

During the design and testing of the power-conditioning and storage equipment, it was found that current and comprehensive technical information on lead-acid and nicad batteries was very difficult to obtain. Building a battery-charging circuit may appear at first to be a simple task. But to build one that does not damage the battery, seriously degrade its performance, or doom it to an early death is not really as straightforward as one might expect.

An excellent handbook has just become available on this topic entitled *Handbook for Battery Storage in Photovoltaic Power Systems,* February, 1980. The 120-page handbook was prepared for the Department of Energy by Bechtel National, Inc., and contains a wealth of engineering data on most types of rechargeable batteries. It includes a section on advanced batteries now under development primarily for electric vehicle applications. The handbook is well-referenced and includes an extensive listing of battery manufacturers, suppliers, and developers. A limited number of copies are available at $9.95 (including handling and postage) from: Moonraker East, Publications Department, Box 117, Riva MD 21140.

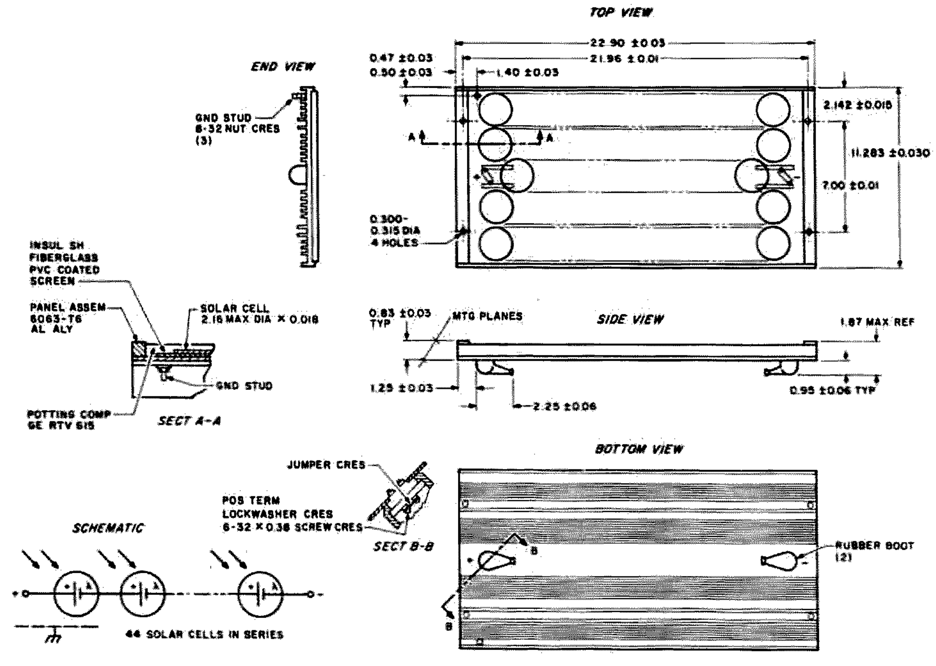

Fig. 1. Diagrams of PV module.

Design Considerations

A simple constant-voltage charging circuit was considered, which would have eliminated the need for the 16-V nicad battery by connecting the PV array directly to the 12-V auto battery through a regulator. While the overall efficiency might have been slightly better, the design was rejected for several reasons:

1) The lead-acid auto battery would discharge continuously at night due to the power demands of the repeater, with the terminal voltage falling to about 11.5 V by dawn. The PV array would then start to charge the battery with currents rapidly increasing to almost 9 Amps and, as the battery attained full charge, its terminal voltage would climb to about 15 V. This wide swing in supply voltage was not considered conducive to stable repeater operation, or to extended battery life.

2) Nicad batteries are much better suited for repeated charge/discharge cycling and are far more resistant to damage from overcharging.

3) The two-battery circuit provides an almost constant supply voltage to the repeater by continuously trickle-charging the lead-acid battery around the clock, not just when the sun is out.

4) The two-battery circuit design appears to be much more fail-safe in that a regulator failure would not cook the lead-acid battery, as it could in the simple circuit. Component failure in the two-battery circuit likely would result in a decrease in repeater performance noticeable over a period of days, allowing time to correct the problem rather than resulting in a sudden complete repeater failure.

This last consideration is an important factor in the operation of our repeaters, since routine inspection of the system is limited by the requirement that someone must climb the 10m structure, and thus periods of unattended operation of a month or more are expected. But this is all just theory and we should know much more about the reliability of our solar-powered repeater in a year or so.

PVs: Current Technology and Future Potential

The principle of the photovoltaic effect was discovered by Edmond Becquerel back in 1893, but useful energy conversion devices have been available only for the last 25 years. An early PV application was in photographic exposure meters. The first breakthrough in PV cell manufacture for electric power generation was made by researchers working at Bell Laboratories in 1954. Subsequently, high-reliability single-crystal silicon PVs were used as an energy source for U.S. and Russian space vehicles thoughout the 1960s. A few terrestrial PV devices were marketed on a trial basis as early as 1959 using silicon cells rejected by the space program as not meeting NASA's high-reliability requirements, but the first PVs designed specifically for terrestrial use were not produced until 1973. Thus, we are dealing with a very new product only recently available in the marketplace, and it is probable that PV applications will grow rapidly in the coming years, especially if anticipated tenfold PV cost reductions can be achieved.

Photovoltaic cells have much in common with transistors and utilize semiconductor technology to convert light into electricity. They consist of a junction of semiconducting material formed by one of three methods: (1) adding impurities (dopants) to one side of a pure material (homojunction); (2) joining two dissimilar semiconductor materials (heterojunction); (3) joining a semiconductor to a metal (Schottky junction).

The combination of materials creates a potential difference across the junction, with the materials on each side of the barrier having different electrical characteristics. One side has excess negative charges and is called n-material, while the other side has excess positive charges and is called p-material. Absorption of light in the semiconductor energizes the negative and positive charges and creates an electrical current when the absorbed energy is greater than the material's energy bandgap.

Fundamental restrictions of quantum physics limit the portion of the sun's spectrum which can be utilized by solar cells and the efficiencies which are achievable. Thus, each different cell design has a unique performance characteristic across the spectrum of sunlight from ultraviolet to infrared. Light with energy below the material's bandgap is insufficient to generate a current; light with energy above the bandgap produces energy equal to the bandgap, with excess energy resulting in heat which must be dis-

sipated. The direct-current electricity that is produced is collected by a contact grid imprinted on the surface of the cell.

The capability to control the energy bandgap and the electrical characteristics of the materials on each side of the barrier is fundamental to the science and art of photovoltaic cell design. Particularly for terrestrial photovoltaics, the technical problem is to construct and control these sophisticated material characteristics in a mass-production process.

Manufacturing of the cell, or a module (panel) of cells, is complete when anti-reflection coatings and protective encapsulants are applied. Single-layer anti-reflection coatings can reduce average reflective losses from 40 percent to as little as 10 percent, and double-layer coatings can further reduce reflective losses to about three percent. Glass, plastic, or silicone encapsulants seal the panel of cells against environmental elements and are a key factor in determining the useful life of the cells. The output of a terrestrial solar cell in peak Watts (Wp) depends on the daily insolation in each location.

On a clear day, the sun's energy reaches the Earth at a rate of about one kilowatt per square meter. This is equivalent to the energy contained in a gallon of gasoline for every 10 minutes the sun shines on an area the size of a tennis court. Even with the low efficiency of today's solar cells (say, 10%), 60 square meters of cells with adequate storage under optimum conditions can provide the needs of an average single-family residence 6 kWp, 700 kWh per month). Unfortunately, such an installation would be far too expensive for an average homeowner. For example, at a PV module price of $10/Wp, the cost would amount to $60,000 just for the PVs, and the installation, energy storage, and power conditioning equipment would be extra.

That is precisely why the Department of Energy is spending over a billion dollars on a 10-year program to develop the technology and production techniques needed to reduce the cost of PVs to $.50-$1.00/Wp by 1986. By then, utility electric rates will be considerably higher and PVs should be able to compete on a sound economic basis. But what are DoE's chances of pulling this off, you might ask? Of course, no one really knows, but DoE is fairly confident that the price goal can be achieved. So much is happening in the PV field (advances in competing cell materials such as silicon, cadmium sulfide, gallium arsenide, encapsulation improvements, better and lower-cost manufacturing techniques being developed) that it is just too early to attempt to select the best technology/manufacturing mix. The next few years may bring several major breakthroughs in PV material technology providing lower-cost cells and in developing cells with much higher efficiencies.

One particularly promising avenue of PV research involves the use of lenses or reflectors to concentrate the light striking the PVs. Concentrations equivalent to many thousands of suns have been tried with very encouraging results. A recent breakthrough was achieved with one type which is called a thermophotovoltaic cell, which reached an efficiency of 26 percent. This particular device utilizes concentrating mirrors to focus the light on a spectral converter which absorbs the full spectrum of sunlight, then reradiates the energy at specific wavelengths which match the optimum operating bandgap of the cell. Ultimately, 30- to 50-percent efficiencies are expected.

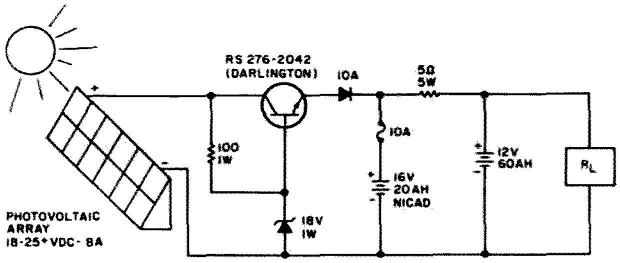

Fig. 2. Power conditioning and storage circuit.

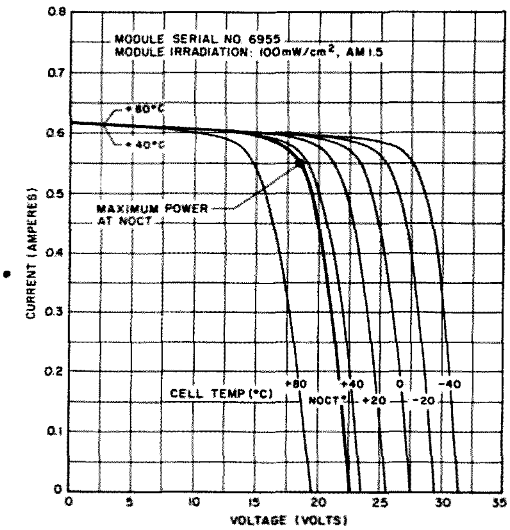

Fig. 3. Specifications of photovoltaic array.

Much of the R-&-D effort on concentrating PVs has been privately supported, and it is still too early to tell just how much of a competitor they will be to flat-plate non-concentrating options. But the overall trend is plain; the immense potential of PVs is no longer just theoretical, and the question now appears to be one more appropriately stated in terms of how long will it take PVs to capture a significant market share.

Photovoltaics and Repeaters

The use of PVs to power amateur repeaters provides us with new opportunities to locate our repeaters at sites which offer better coverage, but which otherwise may not be usable because of a lack of electricity. PVs with battery storage also provide a much greater degree of communications reliability during local emergencies accompanied by commercial power outages (as is often the case). Although many repeater clubs are equipped with auxiliary generators, it is often not easy to find a member who is willing (or able) to hurry over to the repeater site in the middle of a flood or blizzard, start up the generator, and keep it running during an extended power outage.

At the present time, high cost is one of the major problems hindering use of PVs by amateurs. Eventually, prices will come down, but it will take a number of

years, and in the meantime our repeaters will remain dependent on external power. This is a situation where a little creative groundwork could be of great service to amateur radio. Here's how: The Congress is very anxious to accelerate the commercialization of PVs and for the past few years has appropriated millions of dollars over and above agency requests with the intent of stimulating PV manufacture and use. But it is not always easy for the administration to effectively utilize all of the funds; hence, most deserving PV projects have been welcomed with open arms.

Amateur radio spokesmen could approach the newly-created Federal Emergency Management Administration with a proposal to solar-power a number of repeaters throughout the country, to strengthen the nation's emergency preparedness. The Federal Emergency Management Administration, in cooperation with the Department of Energy, might provide the PVs at no cost to repeater clubs as part of the PV accelerated commercialization program. The whole program could be coordinated at the user end by the ARRL.

The federal cost of a program to solar-power 1000 repeaters based on today's PV prices and a collector system similar to ours would be less than $5 million. This is a pretty small part of a billion-dollar PV program budget, and not only that, the real benefit the nation would gain from such a program would far outweigh its very modest cost. So how about it, ARRL, is anybody there in Newington listening? ■

Transmitter Tune-Up for Blind Hams

—an audible indicator for power out

James D. Burney WA4LBX
42 E. Lakeside Drive
Florence AL 35630

Blind hams have used a variety of devices to tune their transmitters, with the conversion of visual indications to audio tones being the most common approach. A blind friend, W5KUY, recently asked me to build a coupler to insert in his coax to sample the rf voltage. This voltage would be used to drive a voltage-to-frequency converter. After looking at his converter with its three transistors and two transformers, I decided to build a more up-to-date version to go with the new coupler.

The audible tuning aid described in this article operates on the assumption that maximum power trans-

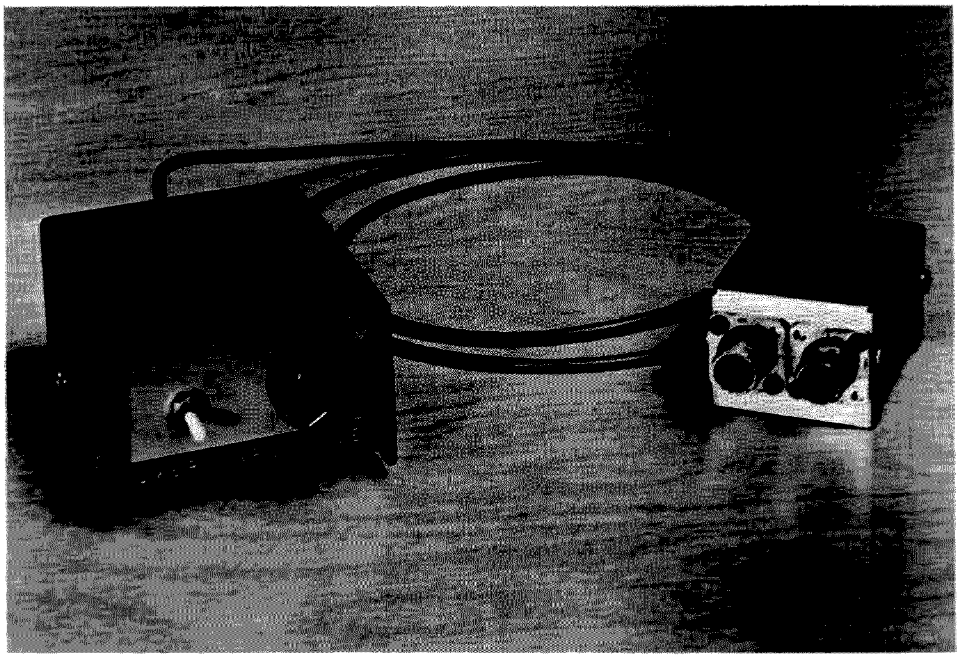

Photo A. Complete audible tuning aid.

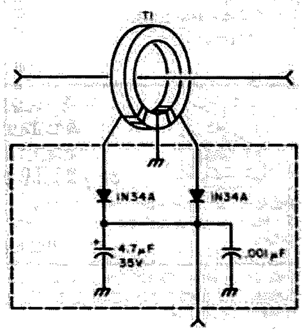

Fig. 1. Rf coupler. T1 = 60 bifilar turns #30 enameled wire, center-tapped, on an Amidon T-68-2 toroidal core (see text).

fer from the transmitter to the antenna will occur when the transmitter is properly tuned. Rf power is sampled by inserting a coupler similar to the ones found in wattmeters into the feedline following the transmitter or linear amplifier, if one is used. The coupler is connected by a length of shielded microphone cable to a voltage-to-frequency converter constructed around a 555 timer IC.

The circuit for the rf coupler is shown in Fig. 1. It is built in a 2-3/4" × 2-1/8" × 1-5/8" minibox. Two SO-239s are mounted next to each other in the small end of the box (Photo B). A two-inch length of center conductor and inner insulation from a piece of RG-8/U is prepared by removing a half inch of insulation from each end and bending the bare wire at right angles on each end, so that it fits into the center contacts of the SO-239s.

The rf transformer is wound on an Amidon T-68-2 core. To make the transformer, take two lengths of #30 enameled wire, each five feet long, and twist them together with about five turns per inch. Wind 60 :urns of this twisted pair on :he core. You will find that 30 turns will fill the core when the turns are evenly spaced. When these turns are on, continue winding he remaining 30 turns over he first layer until all 60 urns are in place. Trim the ends to about three inches and untwist them back to he core.

Scrape the insulation off of all four ends to within an nch of the core and locate he start and finish ends of ach wire with an ohmmeter. Twist the start end of ne wire and the finish end f the other together to orm a center tap. Slip the oroid over the wire from ne RG-8/U that you previusly prepared; it should be a snug fit. You now have an rf transformer with the center wire constituting the primary and the secondary consisting of 120 turns, center-tapped.

Mount a three-lug terminal strip in the center of the large side of the box and an RCA phono jack and ground lug set in the end opposite the SO-239s. Solder the center wire of the transformer to the center terminals of the SO-239s. The center tap of the secondary is soldered to the center ground lug of the terminal strip, and the ends of the secondary are wrapped around the two insulated lugs.

A 1N34A diode is connected from each end of the secondary to the center terminal of the RCA jack, with the cathode band of each diode positioned toward the RCA jack. A 4.7-uF 35-volt electrolytic or tantalum capacitor and a .001 disc capacitor are also connected from the center of the jack to its ground lug, and all joints are soldered. This completes the coupler, and the other half of the minibox can be attached.

The voltage-to-frequency converter is housed in a utility box measuring 3-1/4" × 2-3/16" × 4". Fig. 2 shows the circuit of the converter. Voltages between 1.7 and 9 volts applied to pin 5 of the 555 timer IC cause the oscillation frequency to vary. With the values given, the frequency of oscillation will be about 10 kHz with less than 1.7 volts applied to pin 5. As the voltage is increased above 1.7 volts, the frequency of oscillation will decrease in a linear fashion until the voltage reaches 9 volts, at which point oscillation will stop.

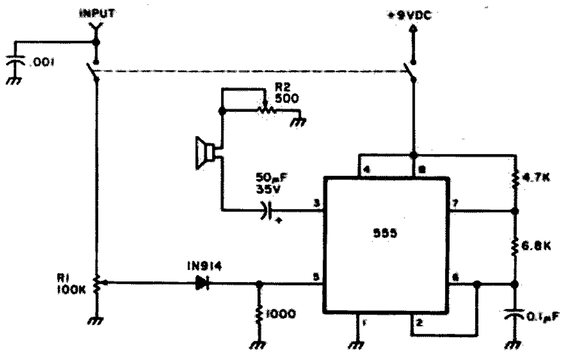

Fig. 2. Voltage-to-frequency converter schematic.

Potentiometer R1 controls the voltage reaching pin 5. When R1 is adjusted to place maximum resistance between the wiper and ground, approximately 20 Watts of output power from the transmitter will begin to lower the audio tone from the converter, and 100 Watts will lower it to about 1 kHz. If higher power is used, adjustment of R1 will set the tone to a usable frequency.

All parts for the converter are mounted on a printed circuit board with the exception of R1, R2, the power switch, and the speaker. An etching pattern for the circuit board is shown in Fig. 3. Although I used a panel-mounted potentiometer for R2 (the volume control), a printed circuit type can be used with only a

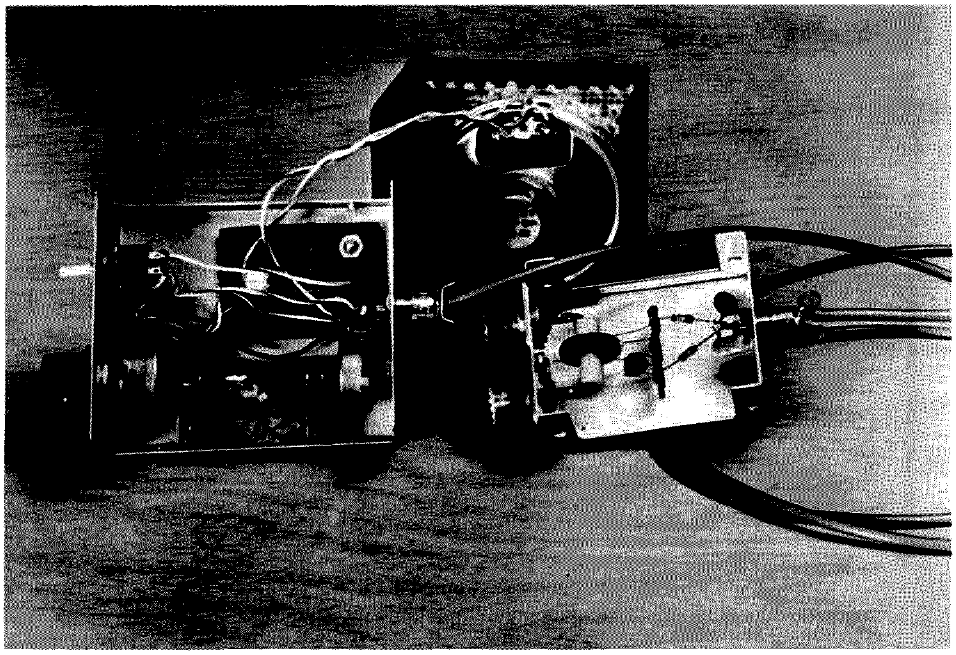

Photo B. Assembly details. Voltage-to-frequency converter is on left, rf coupler is on right.

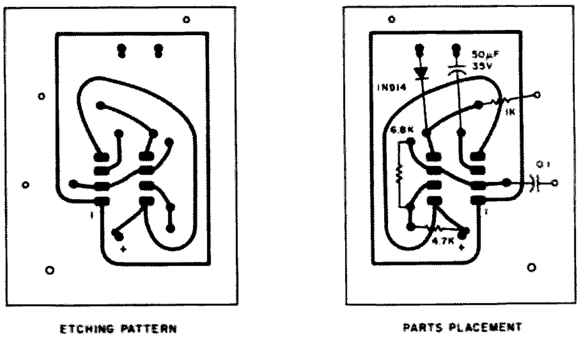

Fig. 3. PCB layout and parts placement.

minor modification to the circuit board. Input voltage from the coupler is through an RCA phono jack on the rear wall of the enclosure along with R2.

The DPDT switch shown is necessary to remove voltage from pin 5 of the IC when the converter is not in use. I failed to remove the input voltage while breadboarding the circuit, and the IC got very hot in a hurry. The resistors are all 1/4 Watt. C1 is mylar™ and C2 is either electrolytic or tantalum.

Since I did not want any bolt heads showing on the outside of the cover, I mounted the speaker by fastening it with hot-melt glue. I cut a 2" diameter hole in the cabinet top with a wing cutter in my electric drill. Next, I glued a piece of perforated aluminum to the inside of the cabinet, painted it, and then glued the speaker to the underside of the cabinet top.

I mounted the circuit board by removing the screw from the left rear foot of the cabinet and drilling out the hole to clear a 6-32 bolt. I then reattached the foot with a 1-inch-long 6-32 bolt and nut. I ran another nut about halfway down the bolt, put the circuit board on the bolt, and tightened a third nut on top of the board. Be sure to scrape the paint away from around the inside of all mounting holes to ensure good electrical contact. The battery is fastened down by making a loop of masking tape with the sticky side out and pressing it between the battery and the bottom of the cabinet.

As with any construction project today, finding the parts is a major part of the job. Most of the parts are available at Radio Shack, and I have added a parts list with Radio Shack part numbers where available to aid in locating the parts.

Operation of the audible tuning aid is very simple. Just insert the coupler in the antenna feedline and connect it to the converter with a shielded cable to prevent rf pickup. The coupler is non-directional, so either SO-239 may be connected to the transmitter input.

When the power switch is turned on, a high-pitched tone will be heard from the speaker. Adjust R2 for minimum usable volume to preserve battery life. Apply transmitter power and tune the transmitter for the lowest tone pitch from the tuning aid. For power levels up to 100 Watts or so, R1 should be set to minimum resistance between the input and pin 5 of the IC. If the tone stops during the tuning procedure, advance R1 until a high-pitched tone is reestablished. When further tuning of the transmitter results in no further lowering of the tone frequency, the transmitter is tuned for maximum output and is ready for use.

I hope this tuning aid will help amateurs with visual limitations to enjoy their hobby more. Other uses of the voltage-to-frequency converter can be made (such as audible voltmeters and other test instruments) with changes in the input circuitry. I would be interested in hearing of such uses which others find for the converter. ■

Parts List

Component	Radio Shack Part Number
50-uF, 35-volt capacitor	272-1027
0.1-uF dipped mylar™ capacitor	272-1069
0.001-uF disc ceramic capacitor	272-126
4.7-uF 35-volt capacitor	272-1012
100k-Ohm potentiometer	271-092
1000-Ohm, 1/4-Watt resistor	271-023
4700-Ohm, 1/4-Watt resistor	271-030
6800-Ohm, 1/4-Watt resistor	271-032
1N34A diodes	276-1123
1N914 diode	276-1122
555 IC	276-1723
DPDT switch	275-614
Battery clip	270-325
2-1/2" speaker	40-247
SO-239	278-201
RCA phono jacks	274-346
Minibox	270-235
Utility box	270-251

The T-68-2 toroid core is available from Amidon Associates, 12033 Otsego Street, North Hollywood CA 91607. Radio Shack does not stock a 500-Ohm panel-mount potentiometer. If the circuit board is modified for a PC-mount pot, part number 271-226 may be obtained from Radio Shack.

Installing Subaudible Tone Encoders

—do it right

Today's communication channels are becoming more crowded every day, and with the increasing amount of intermod and other interference, amateur repeater systems are incorporating tone-access systems to help solve these problems. Probably the most common use of tone-control signaling in FM two-way radio is the continuous-tone-controlled squelch system (CTCSS). This consists of a low-level subaudible tone, typically below 250 Hz, being modulated on the radio frequency carrier of an FM transmitter.

One of the most difficult aspects of connecting CTCSS equipment to a radio is locating the proper injection point for the subaudible encoder. Depending on the encoder used and the type of radio in which the encoder is installed, this procedure can be relatively easy or it can produce many hours of frustration. This article will describe some of the problems of installing a subaudible encoder and will guide you to the successful installation of these units.

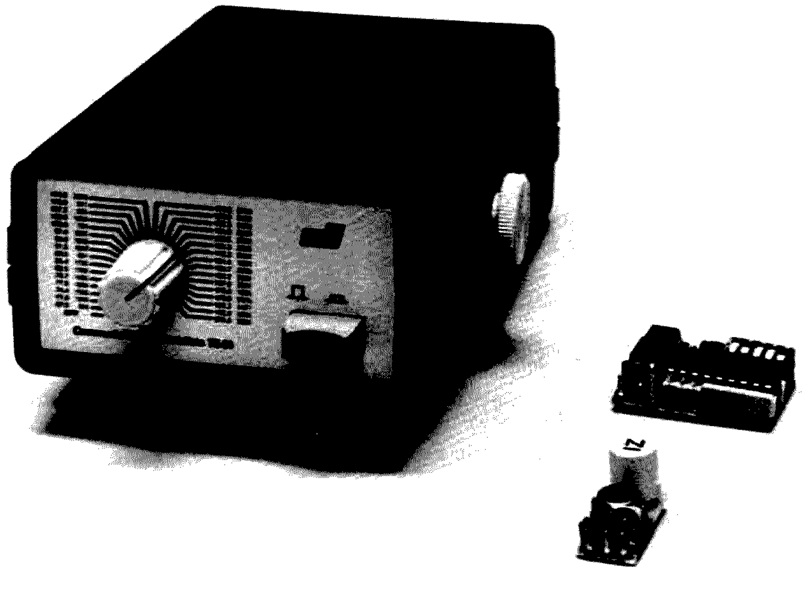

Photo A. This is an example of the types of subaudible encoders available with low-impedance outputs. Moving clockwise from the top is the TE-64 universal encoder, capable of encoding all 32 CTCSS tones via a front-panel switch. Next is the model SS-32 programmable encoder which can be programmed without the use of a frequency counter. Third is the model ME-3 microminiature encoder which uses field-replaceable, plug-in frequency-determining elements. All units are manufactured by Communications Specialists in Orange, California.

Proper connection of a subaudible encoder is very important. If the correct connection point is not found, the result can cause serious system problems. These problems include an excessive buzz on the carrier; loss of microphone audio, loss of transmit power, and intermittent or unreliable operation.

The key to locating the proper tone-injection point involves looking at two areas. First, how universal is the encoder? Is it capable of driving a low impedance load? Second, does the transmitter have a phase modulator or an FM modulator? Are you using a synthesized transceiver? These are just a few of the questions which are important to the proper installation of

the encoder.

Fig. 1 shows a block diagram of a typical phase-modulated transmitter. Most transmitters using individual crystals for each transmit frequency are of the phase-modulated type. The output of the subaudible encoder is typically connected in or just prior to the modulator stage in the transmitter. If the transmitter has a subaudible tone connection point, this point should be used. Do not confuse this connection with another common point often referred to as *tone input*. This is normally used for touchtone™ pads or audible encoders, and is not satisfactory for subaudible connections. This is primarily because this point is usually located in the microphone amplifier section of the transmitter (more on this later).

A radio manufacturer's connecting point is often to the center of the deviation control (sometimes called the IDC control), to the input of the final audio driver, or directly to the varactor modulator diodes. Should the transmitter not have provisions for tone injection, one or all of these connection points should be tested, and the one that provides the best results with minimum distortion and a minimum amount of voice intermoding should be used. This connection point varies with each different model radio, and you must determine which provides the best results.

In some cases, amateur transceivers are not designed to interface readily with tone-coded squelch systems, and injection of the subaudible tone sometimes can be very difficult. In these cases, when using a phase modulator, a varactor assembly can be used. The varactor changes ac voltage into changing capacitance which truly FM modulates the transmitter.

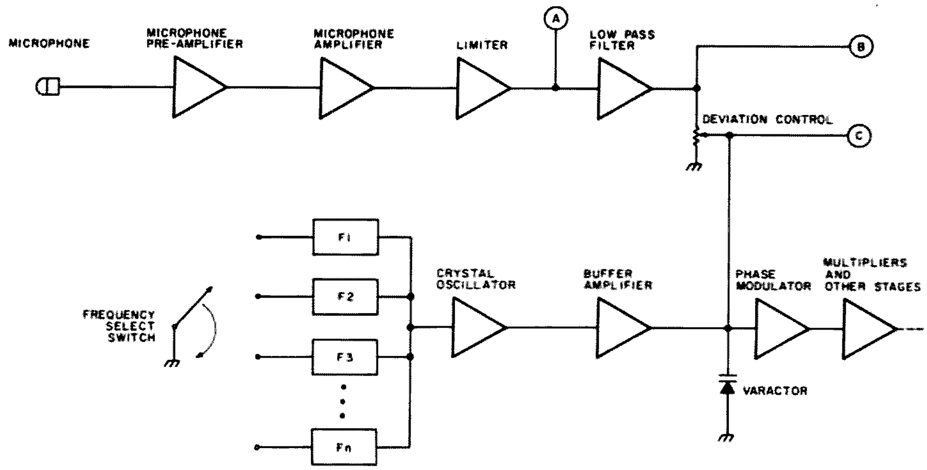

Fig. 1. Partial block diagram of a phase-modulated transmitter. The points labeled A, B, and C are typical connection points for the subaudible encoder. These points are located after the audio-shaping circuitry which would cause tone distortion.

No intermoding or distortion of the voice will be noted with this method, as compared to some injection points in the phase modulators.

Fig. 2 shows a typical varactor assembly, where the collector-base junction of a low-frequency NPN silicon transistor is used as the varactor diode. Various values of coupling capacitors are shown for different frequency ranges of the transmitter; a higher value of capacitance will increase the deviation level. However, if the capacitance is too high, it may be difficult to set the transmitter on frequency. It should be noted that when the varactor assembly is connected to the oscillator circuit, the oscillator frequency will probably shift slightly and require retuning. This method is used quite often in tube-type transmitters and in a few solid-state units, as well. This method also can be used if other connection points prove unsuccessful.

Another common type of transmitter that is now extremely popular is the synthesized transceiver (Fig. 3). This type of radio often uses a frequency modulator whereby a varactor, as described before, is used to vary the frequency of the crystal oscillator. In some transceivers, the varactor is used to change the frequency of a voltage-controlled oscillator (vco). This type of modulator interfaces quite well with subaudible encoders.

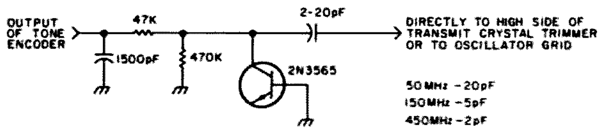

Fig. 2. Schematic of a typical varactor assembly. The collector-base junction of an NPN transistor is used as the varactor. The output of the assembly is connected to the high side of the transmit crystal trimmer. In a tube-type transmitter, the output is often connected to the grid of the oscillator tube. The value of the coupling capacitor changes, depending on the frequency range used. The values shown are approximate and may require adjustment to obtain the proper deviation level.

The frequency-modulated transmitter is very similar to the phase-modulated transmitter up to the low-pass filter section. The FM modulator is identified quite easily, as the audio is fed into the varactor, which is often part of the crystal oscillator. The tone-injection point for a frequency-modulated transmitter is found in a similar manner as with the phase-modulated transmitter.

When connecting power to the encoder, be sure to use switched power that is active only during transmit. This voltage can be taken right from the transmitter circuit board or a push-to-talk relay coil. Switched power should be used for two reasons. First, the encoder will draw current only during transmit since it is not used during receive operation. Second, the crystal oscillator, which is frequency modulated during transmit, is often the same oscillator which is used during receive operation. If the encoder is not disabled during receive, a buzz will probably be heard through the speaker as the encoder continues to modulate the receiver oscillator.

If you have an encoder that has a low-impedance output, insufficient level output should never be a problem. However, if the tone connection point is a high-impedance load such as a 100k deviation control,

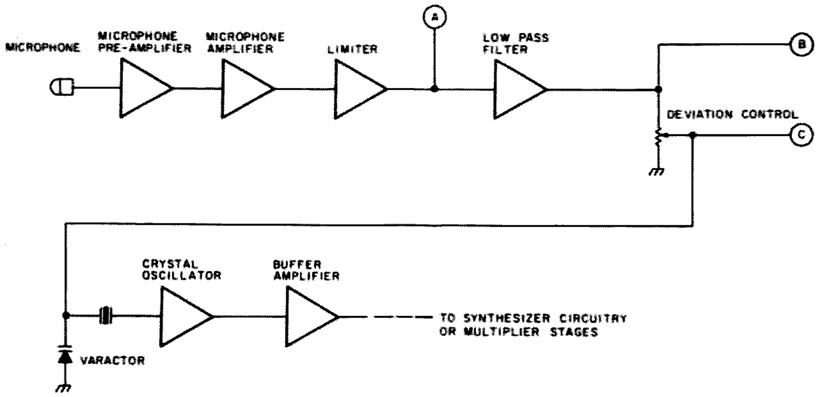

Fig. 3. Partial block diagram of a frequency-modulated transmitter. Although these transmitters are generally a lot easier to interface, some synthesized transmitters using FM modulators can be difficult.

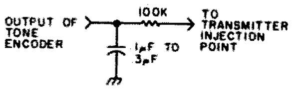

Fig. 4. Tone output filter.

then a series isolation resistor will be required so as not to load down the normal voice modulation. This resistor value must be determined experimentally, but a 100k resistor would be a good starting point. This value could change from 10k to 1 megohm, depending on the radio used. It is best to use an encoder with a low-impedance output (less then 10k). This is more easily adaptable to various types of transmitters, since the encoder often is required to drive into a low-impedance load. If the tone deviation cannot be set up to the proper level, it is possible that the encoder is not supplying a sufficient output level. This would be the case when using an encoder with a high-impedance output to drive a low-impedance load. If this happens, another connecting point must be located which is at a higher impedance level.

Do not connect the encoder tone to the microphone input or the microphone preamplifier as this invariably causes excessive tone distortion due to the frequency response of the transmitter's speech amplifier. The speech amplifier has a typical response of 300 Hz to 3000 Hz and does not permit the fundamental tone to be transmitted. This is the usual cause of a distorted tone output as monitored through a speaker or with a deviation scope. If the purity of the encoder output is in question, look at the output of the encoder with an oscilloscope.

If tone distortion continues to be a problem, then a capacitor can be placed on the tone output to provide additional filtering when required (see Fig. 4). This is not noticeable in phase modulators, since the frequency response can be quite poor at the low end of the audio range. If a deviation scope is used, the scope trace will not be a pure sine wave and will sound like a buzz. The additional filtering will cure the problem. If a deviation scope is not available, then another receiver on the transmitter's frequency can be used. Using this method, an oscilloscope can be connected to the discriminator output in the receiver, and a clean sine wave should appear when transmitting.

Another area which should be given special attention is rf interference. This is most common when installing encoders into hand-held portable transceivers. Although the encoders tested were not susceptible to being affected by rf, care should be taken when installing the units near the transmitter circuitry. In most cases of rf interference causing loss of audio or loud buzzing oscillations, it has been found that the rf is coupled into the connecting leads of the encoder and then fed back into the transmitter itself. This causes the bias conditions and other tuned circuits to become unstable, producing oscillations and distortion. But, under these conditions, it should be noted that the encoder is still working properly. The solution to this is to keep all leads as short as possible and install one or more bypass capacitors on the radio's circuit board where the encoder leads are connected. Also, relocating the encoder or rerouting the connecting leads through another part of the radio should correct the interference caused by the stray rf.

One final problem which is common when connecting tone-coded squelch equipment is setting the encoder to the proper deviation level. Unless you have access to a communications monitor with a deviation scope (not a deviation meter!), setting the proper level can be very difficult. If the proper injection point is not found, you could be encoding a highly-distorted tone which would have to be set at a very high level in order to open the associated decoder. If you are encoding a clean sine wave, then follow this procedure for setting the level:

1) Turn the level adjustment all the way down so that you have zero output and move to a repeater requiring tone access.

2) Next, turn the level up just a little bit and key your transmitter.

3) Did your transmitter key up the repeater? If not, repeat step 2 and continue to increase the level until the repeater keys up reliably.

4) Now increase the level just a little bit more, and you are finished. This little extra level will help you in marginal signal areas, and will operate the decoder more reliably.

5) Button up the radio, and you are on your way.

If you happen to have access to a deviation scope, then the proper deviation level of the subaudible tone should be set from 0.5 kHz to 1.0 kHz peak-to-peak. This is the standard range for this setting. However, it is best to keep the deviation as low as is practical within this range as long as reliable operating is maintained.

It should be clear that installing a subaudible encoder to a transmitter is not an easy job. There are many variables to contend with and each one of them can cause a multitude of problems. But, with practice and experience and, of course, a little patience, excellent system operation can be attained.

I would like to thank the various manufacturers of tone equipment for providing the test equipment and information required for this article. I would also like to thank them for the use of their new line of encoder products which were used for testing and evaluation. ■

Four-Band Mobile Antenna

—looks like a weird hat rack

Do you ever find yourself cruising down the highway working forty meters and wishing you could switch to twenty, fifteen, or ten without having to stop to change resonators? You can! I experimented with this contraption in 1960 and have been using it ever since. There is even a commercial version that came out a couple of years ago.

Any set of three resonators may be used but I prefer the 40-20-10 combination since you also get a 15-meter fallout from it. When I first started using it with an old Galaxy V, I installed a remotely-operated super-tuner gizmo in the trunk, but later found that with patient stinger adjustments on the three resonators, the tuner was not really needed. I am presently using an Atlas 210 for mobile, and the broadbanded rigs are supersensitive to swr over 1.5:1. I have worked many foreign countries with this rig with good signal reports.

The strap that holds the resonators must be of sufficient strength to prevent the angles of the forward and aft resonators from changing. Changing this angle affects the resonant frequency. The strap I happened to start out with was about one inch wide and 3¼ inches long. A hole large enough to accommodate the threaded extension on the mast is drilled in the center. (I happened to have had all Hustler equipment so that is what I have used since.) The other holes on each end are large enough to hold non-corrosive bolts that will screw into the bottoms of the other resonators. The strap is bent as shown with each end dropped at forty-five degrees. The assembly is attached to the mast and held in place by the center resonator, and the time-consuming tuning is started.

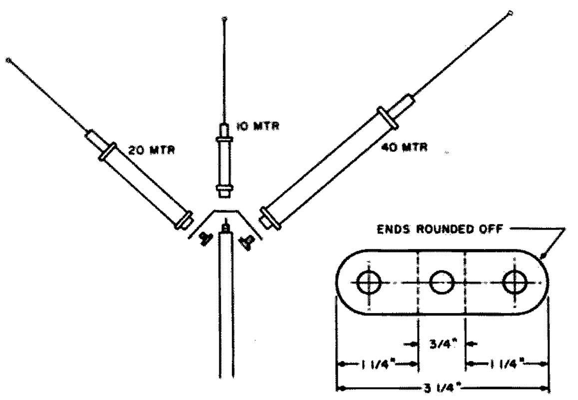

Fig. 1. Four-band mobile antenna construction details.

Begin with the lowest frequency resonator, adjusting to the lowest swr, then proceed to the next higher and then the last. The resonators interact, and this procedure must be repeated several times until the swr no longer can be improved. I have 1.1 at 7.260 and 1.35 at 7.225 and 7.295. On twenty meters, the swr is less than 1.35 across the band and even better on ten. The swr does peak up to 1.5 on fifteen meters. I use the ten-meter resonator to hold the strap to the mast with the twenty-meter resonator in front and the forty-meter aft. This streamlines the assembly in the direction of travel and reduces wind resistance. Also, with the larger resonator aft, it tends to stabilize the assembly at normal highway speeds.

I have found that the majority of the noise associated with mobile reception can be eliminated by using the copper braid out of RG-8 coax as grounding straps and grounding the car hood and trunk lid to the frame of the car. In addition, the exhaust should be grounded in at least two places, one in front of the muffler and one aft. Be sure to scrape the rust off to bare metal when attaching the grounding straps. The braid can be cut to the desired length, the ends shaped to hold a bolt, and then heavily soldered to make a good connection.

Several of my ham friends around the country have built this antenna system over the years and have enjoyed it. I would be pleased to hear from anyone who tries it and of any ideas for improvement. ■

Computers and HF

—a discussion of alternatives

Microcomputers are becoming increasingly popular, and they can be used to give us faster and more reliable communications on the amateur bands. But what is the best way to use them? If the FCC offered us a choice of several emission types and transmission speeds for computer communications today, which should we choose? It would be good for us to start now to consider the character of the ham bands we have to communicate over and the nature and potential of the computer links that we want to set up so that later we can go to the FCC with proposals and justifications for what we want.

This article will present my thoughts on how an optimum scheme for computer-to-computer communications on the HF amateur bands should be designed. For purposes of this discussion, whether or not these techniques are authorized under the current FCC rules is immaterial; we can work on the rules after we decide what we want.

Advantages

Why, in the first place, do we *need* a special emission type for use in computer-to-computer communications? Current practice for those with microcomputers running in their ham shacks is to program the computer to emulate a TTY machine. This allows communications with other amateurs using TTY machines, but we can do much better.

Computers will allow us to communicate at much higher speeds than TTY machines. This will reduce the time required for transmission of large data files and also allow retransmission of data that was garbled by fading or QRM without incurring unacceptable overall transmission times in the process.

Computers will allow us to implement error-detecting and error-correcting codes in the transmission of our data. This means that the receiving computer will be able to determine whether or not it has received a particular data block error-free and request retransmission of portions if some were garbled. This is a fantastic step forward compared to current RTTY operation.

By combining the use of computers with frequency-shift keying (FSK) and error-detecting codes, we can obtain another advantage—diversity operation. The receiving computer can detect independently both the mark and space signals. Since these two signals are separated in frequency, the overall system gains immunity to fading of one channel with respect to the other ("selective fading") and also to narrowband QRM such as CW signals which might be obliterating one of the two tone frequencies at any given time.

Uses

There are several immediate uses for interconnected microcomputers on the amateur bands. First, in emergency communications, links with computers supporting them could handle formal message traffic error-free and at much higher rates than either CW, phone, or RTTY operation can today. This could reduce the typical logjam of message traffic out of disaster areas.

Second, the transfer of image data (TV pictures or

computer graphics) from one amateur to another could be done much better using microcomputers and digital techniques than by the current slow-scan TV system. This is because the images could be digitized and sent over the link using error-detection coding. By retransmitting portions of the image that were received garbled, display of a perfect image could be ensured.

Third, people will want to exchange computer programs. This will require a high-speed communications link between computers, with a means to detect and retransmit garbled data, since programs can tolerate no errors.

Now let's discuss an inter-computer communications scheme that is intended to be optimum for amateur use on the HF bands.

Emission

One of the most important characteristics of the HF amateur bands is the typical presence of fading and interference. For operation under these conditions, a frequency-shift keying approach is best. Since it is desirable to keep the signal bandwidth as narrow as possible, use of the present standard FSK shifts of 170 and 425 Hz is recommended. Use of 170-Hz shift would minimize one's bandwidth, at the expense of reduced advantage from diversity operation (the wider the mark-space frequency separation, the better the diversity receiver will work).

On the other hand, on a band that is not too crowded, 425-Hz shift can be used and the system will be closer to being immune to narrowband interference. A shift of 850 Hz would offer even more diversity advantage and also allow a faster signaling speed, but I am not recommending it due to the greater bandwidth required.)

Speeds

Once the frequency shifts are chosen, the maximum signaling speed is set also. This occurs because the significant sidebands produced around each tone frequency must be separated enough to allow reliable detection at the receiver. Analysis shows that we should be able to use a pulse width as short as 7.84 milliseconds (ms) with 170-Hz shift and still allow adequate separation between the mark and space sidebands. With 425 Hz, a minimum pulse width of 3.14 ms should be usable. Both these schemes would require good quality detection filters at the receiver. And in both cases, the system could be slowed down from this maximum rate when band conditions are bad so that added interference immunity could be gained from the longer pulse times.

If we assume use of an asynchronous 8-bit ASCII code, the 7.84-ms pulse width yields a speed of 12 characters per second (cps) and the 3.14-ms width yields 30 cps. Overall emitted bandwidth of the 170-Hz shifted signal at 12 cps would be about 340 Hz, and that of the 425-Hz shifted signal at 30 cps would be about 850 Hz.

Coding

While the Baudot code presently in use for RTTY is most efficient for sending text messages (it requires only a 5-bit code), the 8-bit ASCII code set (with its capability to send special characters and represent full 8-bit computer words) is superior when transmission of all sorts of data is considered. The only penalty in the use of ASCII will be that pure text messages will require slightly longer transmission times than if Baudot coding had been used.

I recommend that we use asynchronous ASCII coding for our inter-computer communications because the design of the receiving hardware and software is simpler. Also, the timing accuracy requirements of the sending and receiving computers are greatly reduced compared to those required with synchronous codes (no start or stop pulses). The code will use a 1-unit start pulse, 8 bits of data, and a 1.5-unit stop pulse—similar to present RTTY coding.

We can take a tremendous step and obtain error-free reception of data by employing error-detecting or error-correcting codes in our scheme. These are special methods of coding the basic ASCII characters of a message so that the receiving computer can determine, after it has received the full message, whether there were any errors in it. If there were, it can request a retransmission of portions of the message from the sending computer. The sending computer can retransmit data blocks that were garbled in transmission whenever necessary until the receiving computer has received the entire message correctly. (There is a catch, of course, in that as more transmission errors occur, data blocks must be retransmitted more often, and the longer it then takes to receive the entire message error-free.)

Since we can expect a lot of interference on the ham bands, it is best to break up the data we are sending into small blocks containing perhaps 16 or 32 characters each. A typical transmission might contain 20 or 30 blocks, and only garbled *blocks* would need to be repeated, not the entire transmission. (This is known as "block coding.")

Diversity

As mentioned earlier, the use of FSK with block coding and error-detecting or error-correcting codes will in turn allow the use of diversity receivers. After detecting both the mark and space signals complete with error-detecting information, the receiving computer can request retransmission of garbled blocks. Since the receiving computer need receive only one of the two signals without garble to receive a complete block, the system is now much more nearly immune to narrowband QRM and selective fading.

What Now?

The hardware and software needed to implement all of these ideas has not yet been completed, but it is under development. Much experimentation will still be required, even within the framework of ideas presented here, to determine which of the several possible schemes is really optimum for use on the HF bands for computer linking. The most experimentation will probably be required in determining which of the many available error-detection and error-correction schemes we want to use. I am starting to work along these lines and would like very much to hear from others interested in participating in this development effort.

The ideas presented here are intended to be a starting point for discussion and experimentation within the amateur community, with the eventual goal being an optimum agreed-to standard for inter-computer communications on the HF bands. Let's give this topic some thought and ensure that the eventual FCC rules authorize us to use state-of-the-art techniques for linking our personal computers. ■

Ned Novice and his Capacitance Meter

—you, too, can build one

Ned Novice visited Mike Cord (the boy electronics wizard) the other day with a perplexing problem pertaining to plastic parts. Ned asked, "Mike, what are these?" and set a box of parts on the workbench.

Mike replied, as he pawed through the box of parts, "They seem to be capacitors with no markings as to value."

"Do you know a way to determine the value of these parts?" asked Ned quizzically.

"First of all," Mike replied, "let's get back to basics."

The Capacitor Defined

"My father's physics book should be of help. Hmm . . . Ah, yes, here it is . . . Q=CV. This says that the charge on a capacitor in coulombs is equal to the capacitance in farads multiplied by the voltage."

"How can that relationship be of use to me?" interjected Ned.

"Quite easy," replied Mike. "If we charge up a capacitor to a known voltage and measure the coulombs, we will have it."

Ned thought for a few moments before retorting: "But I have never heard of a *coulomb* meter!"

Mike grinned and searched through his junk box for a few moments before coming up with a 0 to 100 microammeter. "With this we will measure your capacitors."

"You *do* have a coulomb meter, then," said Ned, hopefully.

Mike replied, "Look at it this way, Ned. The definition of the Ampere is one coulomb per second, so what we will do is measure the current."

Mike wrote the cryptic formula: $I = Qf = CVf$. "We will charge and discharge the capacitor at a frequency. The measurement of picofarads will be indicated by microamps," he stated in a firm voice, with the confidence one would expect only from a more mature individual.

The Circuit Designed

"Now for specific values," said Mike as he studied over the scratch pad for a moment. He wrote down: V=4.5 volts, I=100 microamperes, C=100 picofarads full scale.

"Therefore, $f = I/CV =$ 222 kHz!" exclaimed Mike as he turned off his calculator. "And to change ranges all you have to do is change frequency. Thus, 100 pF = 222 kHz, 1000 pF = 22.2 kHz, .01 uF = 2.22 kHz, .1 uF = 222 Hz, and 1 uF = 22.2 Hz."

Just then Mike's father entered the ham lab and asked what fun the boys were into today. Mike related all that had happened and asked his dad if he had any suggestions.

"So far, so good, Mike.

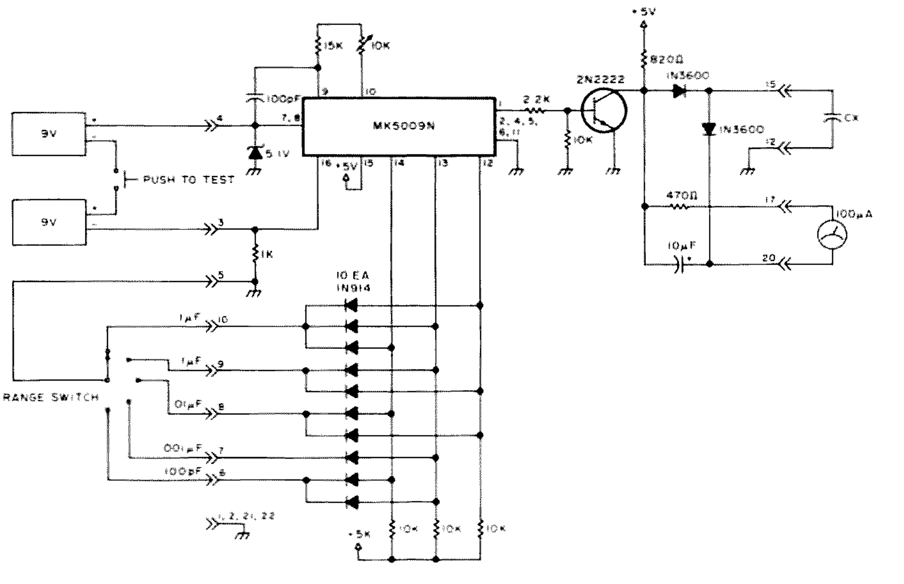

Fig. 1. Capacitor meter schematic.

Parts List

9-V transistor battery	2
Battery jacks	2
Push-to-test switch, SPST	1
Zener diode, 5.1 V, ½-Watt	1
Rotary switch, 5-position	1
Diode, 1N914, 1N697, etc.	10
Diode, 1N3600, 1N198, etc.	2
IC, Mostek MK5009	1
Transistor 2N2222	1
Resistors:	
15, ¼-W, 5%	1
1k, ¼-W, 5%	1
2.2k, ¼-W, 5%	1
470, ¼-W, 5%	1
820, ¼-W, 5%	1
10k, ¼-W, 5%	4
TO5 pot, 10k	1
Meter, 100 dc uA full-scale	1
Capacitors:	
100-pF dipped mica	1
10-uF tantalum, 10 V	1

Circuit board is available from O. C. Stafford Electronics, 427 S. Benbow Road, Greensboro NC 27401.

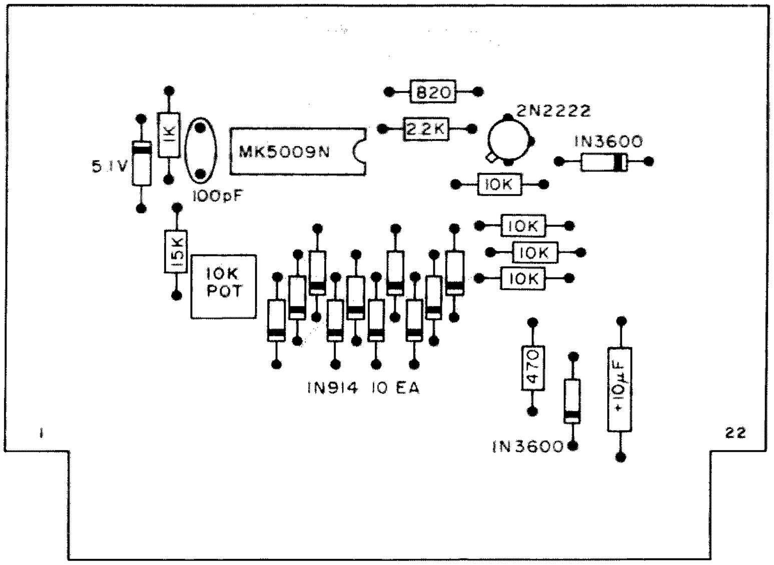

Fig. 2. Capacitor meter parts layout.

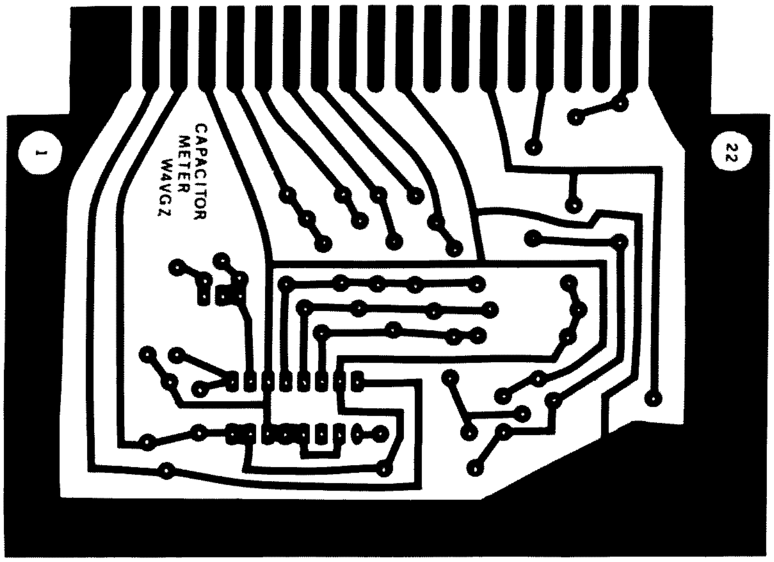

Fig. 3. PC board.

However, I do have a suggestion. Mostek has an integrated circuit that will do all you want in generating a 5-decade range of signals. This chip has an oscillator implemented as well." Dad then reached for the Mostek data book from a crowded bookshelf and drew the schematic shown in Fig. 1.

The Project Built

The next evening, Dad came into the ham lab with a grin and threw a large envelope on the bench. "I had a few spare minutes at work today, so I laid out a PC board for your capacitor meter, and here is the phototomaster."

"Golly, Dad!" exclaimed Mike, "I was going to build it on perfboard, but this is so much better."

Ned was already putting the negative over a pre-sensitized PC board blank and exposing the resist with the photoflood lamp. Mike reached over and turned on the crock pot that contained the ammonium persulfate etchant. A half-hour later, the boys were stuffing the board with parts. Luckily, the local industrial parts distributor had the MK5009 in stock, and Dad had had the foresight to pick one up on the way home.

"What are all these diodes for?" asked Mike.

Dad signed off from his 20-meter QSO. "The decade selection is made by 4 binary-coded lines to the MK5009. I weighed the cost of a BCD thumbwheel switch against the cost of the diodes, considering that we have many rotary switches in the junk box. At 20 for a dollar, the diodes won," explained Dad.

While Dad was explaining, Ned had been soldering wires, and he called from the workbench area, "It works! I tried a .001-uF capacitor and trimmed the oscillator for full scale. Then I measured a 470 pF and the meter was *exactly* on calibration!"

By the next evening, the circuitry was mounted in a nice looking box purchased from the local hobby electronics store. Dry transfer labels were used to mark switch positions, and Ned was busy identifying his unknown capacitors.

"Mike, I have noticed that the meter reads 3 or 4 picofarads on the most sensitive scale, with no connection to the output terminals. This must be distributed capacitance and leakage effects, right?"

"Yes," replied Mike. "Dad explained it to me just that way after you left last evening."

"Mike, what do we do if we have a really large electrolytic to measure?"

"Hmm . . ." said Mike, as he reached for the physics book. ■

Daze of Whine and Noises

—intoxicating information about alternators

One of the puzzling problems that crop up in our VHF FM equipment is the sudden appearance of alternator whine. It is usually the first comment you receive if you have it on your signal. As befits the individualistic aspect of the hobby, there are many myths pertaining to its elimination which I shall attempt to dispel, after which I will suggest some ways of eliminating it. First, however, we should understand the reason for its being, and learn where to look for its source. The charging system in your car is the cause; the reason we have the charging system is to keep the source of all of your car's electrical power at its proper potential; the source being the car battery.

Fig. 1 diagrams the charging system for late-model GM cars. Note that the alternator is a 3-phase full-wave bridge with an output shown in Fig. 2. It is the dc component of the pulsating output voltage of the alternator that charges the battery. Since the output of the alternator will vary with engine speed—anywhere from slow idle of about 600 rpm to several thousand rpm—a regulator is added to ensure an almost constant charging voltage to the battery. This constant voltage is perhaps one to one-and-one-half volts higher than the 12.5-volt battery. Note that the battery is 12.5 volts, not the 12 volts often assumed.

Photos courtesy of Ford Motor Co.

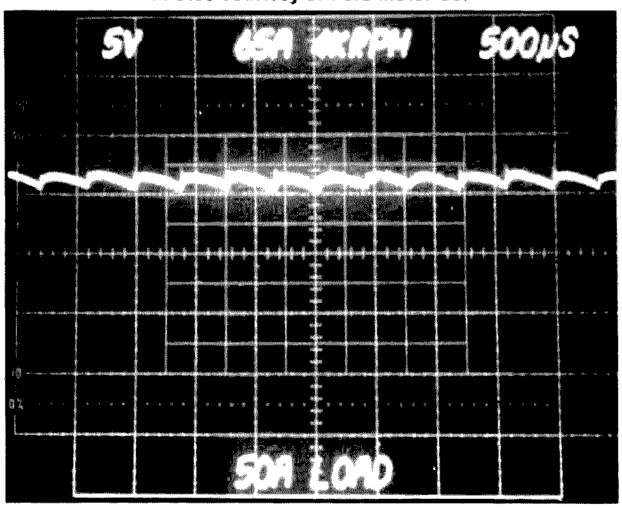

Photo A. Alternator output under actual load condition.

At one time, it was possible to adjust the charging voltage and current. My late-model car is permanently adjusted. The regulator module is mounted inside the alternator. Granted, it is a solid-state assembly, but if the permanent adjustment becomes temporary, the regulator must be replaced in its entirety. A very positive aspect of these new-fangled solid-state regulators is that there are no longer any arcing contacts involved. The older regulators had (at least) one set of contacts (voltage-adjust) opening and closing all the time the engine was running. The spurious radiation from these beauties was stultifying!

Alternator whine is the squeal mixed in with your audio that the receiving stations hear when you transmit. It varies in frequency in proportion to engine speed. The root cause of alternator whine is related to diode switching and the chopping action of the regulator. Rather than the ideal waveform shown in Fig. 2, the output of an alternator is the square wave shown in Photo A—a photo of alternator output under actual load conditions. All the scope-trace photos used a setting of 5 v/cm on the vertical axis and 500-μs timebase for the horizontal sweep.

Square waves contain many harmonics extending well into the VHF range, and since automotive designers may not be aware of the fact that we amateurs are installing VHF equipment in our cars, they don't spend too much time properly routing wiring. Nor do they spend time or additional parts trying to clean up the garbage you will see on a 12-V (sic) bus in the car, should you happen to put a scope on the Vcc line to your radio. They design in only what they have to for general usage. The fact that cars are becoming physically smaller compounds the felony. All wires, by necessity, are closer together.

In most cases, spurious radiation in the audio frequency range gets into your rig via what automotive engineers call backway point of entry. This means

through the "A" lead to your rig. The result of this is the modulation of your signal with an unwanted audio signal, represented by the squeal, in addition to the desired modulation from the microphone. I would hazard a guess that the reason that the whine manifests itself more on the transmitted signal, as opposed to receiver audio, is related to total gain in each audio circuit and the number of stages (discrete and/or IC) in the chain. I have experienced whine in a receiver, but not in its transmitter in one instance, and vice versa in another.

The spurious audio is generated by the unique nature of the alternator system. Its frequency is related to alternator rpm times a constant, K, where K equals the number of poles times the number of phases times the diode rectification factor, all divided by 60 (the conversion of rpm to Hz).

For Ford cars, which use a six-pole alternator, K = 0.6; for GM cars, which use a seven-pole alternator, K = 0.7. With an engine speed of 600 rpm, the alternator rotates at approximately 2400 rpm, since there is about a four-times multiplication factor between the engine pulley and the alternator pulley. The spurious is therefore about 1440 Hz (0.6 × 2400) for Fords—right in the middle of the audio range.

All FM gear uses audio wave-shaping in the receiver audio system not only to de-emphasize, but also to limit bandwidth. Audio is usually cut off above three kHz. Any spurious audio is also reduced in amplitude; therefore, when a radio is transmitting alternator whine, you will usually hear it only at low speeds of travel or at idle speeds. The whine may still be there, but your radio's audio system cuts it off or reduces it by a substantial amount. As a point of information, you can, with a little mathematical manipulation, ascertain that when you rev up your Ford engine above 1300 rpm, a ham, listening for your whine, will no longer hear it. All of this presupposes that your charging system is in perfect working order.

Photos B and C show the results of a failure in one of the rectifier diodes in an alternator. Photo B shows a shorted diode; Photo C, an open diode. Note first that the average output voltage drops just a little but, more importantly, that the waveform is more distorted. Without getting into a Fourier analysis, it follows that more spurious harmonics will be generated along with more spurs in the audio range. This will affect the "purity" of the whine you transmit. Get the hint? If your whine suddenly changes its characteristics, check your alternator diodes! Hopefully, you will have removed this annoying signal from the air long before any diodes break down.

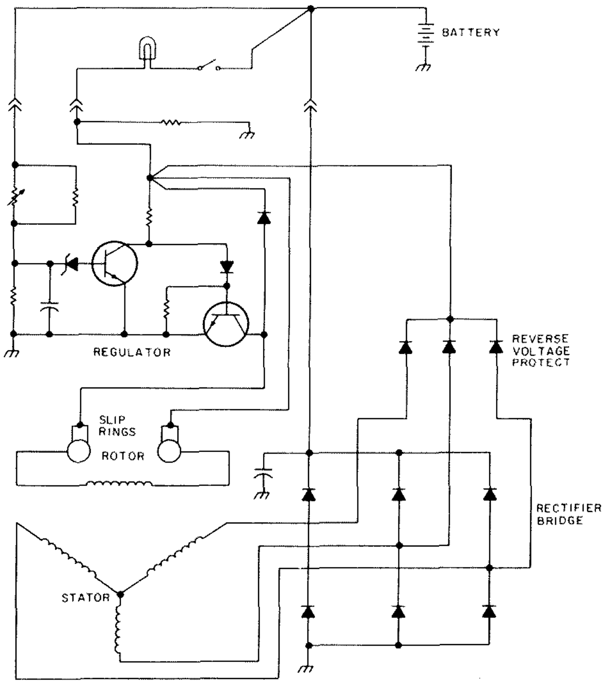

Fig. 1. The charging system for late-model GM cars.

Much has been said, but little written regarding ways to reduce the spurious transmission of whine. The most effective way that I have found, borne out by automotive people I've contacted, is to insert a properly rated choke in series with the "A" line to your radio. A value of about 20 mH worked for me. The most flagrant error made is to attempt to use a standard CB-type choke. These things are rated at only 2 Amperes. Most amateur equipment draws up-

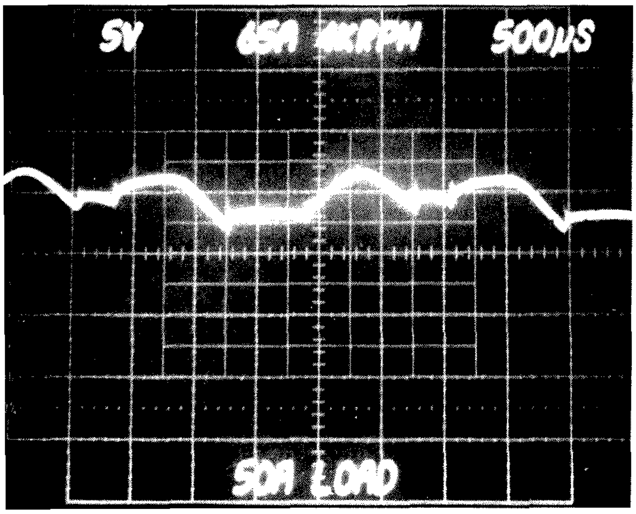

Photo B. Result of shorted diode in an alternator.

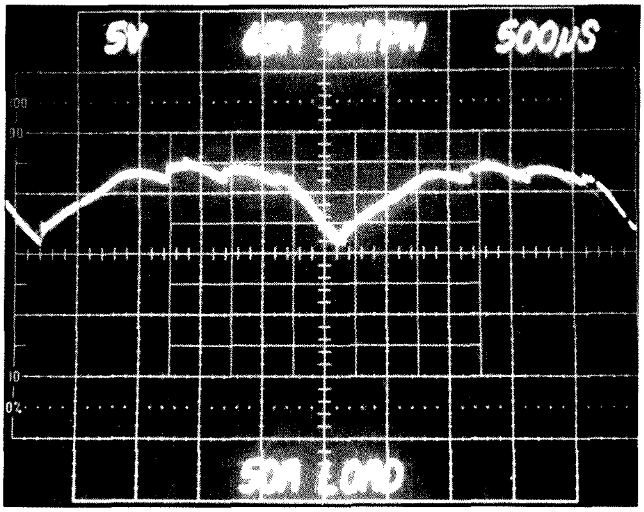

Photo C. Result of open diode in an alternator.

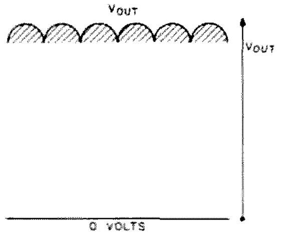

Fig. 2. Three-phase full-wave bridge output.

wards of three Amperes. This amount of current flowing through a choke rated at 2 Amps would saturate the iron core, rendering it useless. There are some 5-A CB chokes available, as well as high-current chokes used with high-power auto stereo systems.

Make sure that there is, in fact, some iron in the choke you buy. I built one on a toroidal core which had strip-iron as its base—not ferrite. Since it involved winding about 100 turns of #16 wire through the toroid, I don't recommend it—unless, of course, your hands are really calloused. I don't find that adding electrolytics across the power line is as effective as a good 0.1-to-0.5-uF capacitor. Among others, Sprague makes an excellent line of feedthrough capacitors (48P series). These should be connected in series with the battery output terminal of the alternator after you check that the capacitor case is truly grounded to the alternator case. Be sure to get a capacitor with an adequate current rating. Remember, the environment under the hood of a car is severe insofar as temperature is concerned.

For years I've been hearing that the only way to eliminate whine is to run the Vcc feed directly to the battery. One problem with this approach is that the batteries in the new cars have terminals that do not lend themselves to adding external connections. The other problem with this approach is that running long lengths of unshielded wires in the engine compartment can cause more problems than using existing wiring.

If you happen to run this new wiring in close proximity to the car wires that are radiating, you're making the job tougher to correct. Your connections should be made with at least #16 wire if there is any appreciable run length. In case you're interested in using coaxial cable for your power connections, be advised that the inner conductor of RG-8 approximates a #12 wire, RG-58 has a #19, RG-59 a #22, and a good "mini 8," a #16 wire.

Bring an AM radio close to your car wiring in the engine compartment, and note the presence or absence of whine. Don't worry too much about the other noises you hear. What you are listening to is the snap, crackle, and pop of the primary and secondary of the ignition system, the myriad solenoids and valves that are now added to the engine for pollution control. The saving grace in all this is that all of the aforementioned snap, crackle, and pop is in the form of amplitude modulation. Our VHF equipment, being frequency modulated, is pretty much immune to these spurious AM radiations. Generally, only whine is the problem.

In view of the number of models of autos on the road, it is obviously impossible to list specific fixes for whine. In general, make sure that you are making good grounds in your installation. If you are connecting your ground to a factory-installed ground, be sure the latter is a *zero resistance* connection to the battery. Arm yourself beforehand with a roll of bonding braid (Belden 8663, 8669, or equal) and literally bond your car together—electrically. You can use the same braid to shield long runs of wire by snaking the wire through the expanded braid and then grounding one or both ends of the braid.

Move some of the wires in the engine compartment away from each other to see if the induced spurs are reduced. Be careful in this operation. The SAE (Society of Automotive Engineers) has had much experience (75 years) in routing wires to prevent them from being wrapped around fans, belts, and other moving parts guaranteed to rip a harness from your car. I cannot stress too strongly the need for good grounding, and one area you should be sure to check is the antenna-to-radio ground connection if you use a magnetic-mount antenna. Remember, the base of this antenna is not grounded—it is insulated from car ground by the paint on the car, rubber gasket, or other nonconducting base material. If you use a gutter-clip mount or a trunk mount, be sure that the mounting screw(s) break through the paint and make zero-resistance contact with the body of the car. These points should be checked regularly to ensure that no oxidation or corrosion sets in to take your antenna off ground.

In my previous car, I used an extra Faston connector in the fuse block as my source of power with a choke in series with my Vcc line. But with the purchase of a new car, I found, much to my chagrin, that GM (at least) changed this connector to a special one, not yet available to the public. Temporarily, I used the cigarette lighter to power my rig with the same choke in the line. According to current myth, this is supposed to be a no-no, but I've had no complaints with that setup. I have since made a direct connection to an unused connector in the fuse block, because the cigarette lighter connection was sloppy and I wanted—or at least my wife wanted—a neater installation. This also provided me with the advantage of ignition-key control of power.

Speaking of cigarette lighters, I have been told that some new cars have reverse polarity. Be sure to check for this, because if you don't have reverse-voltage protection in your rig, you may well cause serious (and expensive) damage to your equipment. When your car is delivered with a factory-installed radio, the manufacturer usually installs a bypass capacitor—probably at the fuse block. After all, they have to have some justification for the prices charged for radios. You might consider tapping the lead that goes to your AM/FM radio for a source of power. This is easily accomplished by three-way pressure taps available in auto supply stores.

In an older car, I once was advised that I had whine where I didn't have it before and that the cause was a "weak" battery; that the internal resistance of the battery was increasing and causing whine. Well, it may have been true that the internal resistance of the battery was increasing with age, but putting in a new battery—which I hastened to do—did nothing to eliminate alternator whine!

Now, after a great deal of time expended in communicating with people at both General Motors and Ford—all of whom have been most cooperative—I have come to the conclusion that eliminating alternator whine must be done at the source—that is, at the alternator. Capacitive bypassing plus a suitable choke in series with the power feed to your radio (at the radio), in addition to good grounding practice should alleviate, if not eliminate, most whine problems. ■

LOOKING WEST

from page 12

this service, I have the knowledge to do so. Why don't I? Simply because I want to see pay-TV flourish. I feel that it has a lot to offer in quality of entertainment and consider the monthly service fee to be the same as money given to support public broadcasting. I am, however, very critical of the subscription-TV services themselves because I feel that the piracy problem is one that they have indirectly generated, and, therefore, it's one that they must solve without government intervention.

SIX METERS: A NEW YEAR'S RESOLUTION

The mail has something to say, and I am delighted with what it says. Amateurs who had put their six-meter gear in the attic or garage are taking it out and putting it back into operation. Others tell me of next-to-nothing purchases that they're making at flea markets. They're gobbling up old Heath Sixer's for 10 bucks or less, and grabbing Gonset Communicators for a song, and Clegg 99ers, radios that for years had been a collector's item, are being put back into service. People are coming back to good old six meters and having fun to boot. Many call it a return to the good old days of ham radio. No, it's not a mass exodus from other bands. In fact, it's not a mass anything—not yet. But movements take time to gain momentum and repopulating six meters will not be an overnight affair.

With the exception of one letter from a VRAC chap, all correspondence received has been highly positive. Some did question the wisdom of a return of activity to six in light of possible severe TVI, but in most cases, those writing said they would chance such a move if some good low-pass filters could be found. Many stated that the low-pass filters marketed may claim a 52-MHz cut-off but that they do not seem to be very effective. True, most are not very effective, as years of six-meter operation have shown me firsthand but, back in the early 60s, there was a very effective low-pass filter. The next time you hit a swap meet, keep your eyes open for a dull-gray aluminum box with the name "Gavin" marked on it. If you can find one of these beauties, you can literally tune away most TVI caused by six-meter transmitters operating below 52 MHz.

As I remember it, the Gavin six-meter filter had 6 sections with a tuning capacitor for each section brought out to the front panel. As I remember it, you first tuned it for maximum forward power and then re-tuned it for minimum TVI. . . and it worked. My buddy, Larry Levy WA2INM, had one of them, and it's the only filter he ever condescended to use on his home-brew six-meter masterpiece.

Larry's transmitter was a 6U8 driving a 6146 with an outboard pair of 1625s as class B modulators. The transmitter was not shielded in any way, shape, or form and completely took out the low VHF band on a TV in the next room. When Gavin came out with their filter, *73* gave it to Larry for evaluation. Reluctantly, Larry installed a coax connector on his transmitter and put the filter in-line. (ed note: Until that time, WA2INM's transmitter had no connectors in the rf circuitry. The only break in the coax came at the antenna changeover relay—an antique itself.) A "tune-for-minimum-scream" technique was employed wherein Larry tuned and waited for the screams of anguish from the other room to subside. Amazingly, in short order they did.

Later on, I borrowed the same filter from Larry and tried it at my place with the same results. In my case, the filter had an even harder job since my 6BQ6 final amplifier tube was also a doubler rich in harmonic content, and the transmitter had a link-coupled output. (ed note: I did use coax connectors and my transmitter was in a shielded enclosure.) The Gavin filter completely eliminated every trace of TVI on both the RCA set in the living room and the old DuMont upon which the entire station sat.

I do not know what ever happened to the manufacturer of this device. For a while they were involved in the consumer-TV antenna business, but seem to have now dropped from sight. Maybe one of you out there knows where they are, or perhaps how to contact someone from that company in relation to obtaining the specifications for their six-meter filter. If we were able to obtain such specifications, along with the necessary clearance to publish the data, I would be happy to do so. The Gavin filter worked; I can attest to this from firsthand experience. I also have the inimitable "INM" to back me up in this one.

Another important matter discussed in the received mail was that of converting older AM equipment to FM. I have personally converted only three radio types to FM service. They were the Lafayette HE-45 series, the Gonset Communicator II, and, believe it or not, one Heath Sixer. The Sixer was the easiest, since the superregenerative detector was broad as a barn door to start with, permitting marginal FM reception as it stands. It's only necessary to FM the transmit oscillator stage using the existing internal modulator, while rerouting the final amplifier B+ supply around the modulation transformer and directly to unmodulated B+.

I should warn you that the early HW-32s that used 50-MHz overtone crystals were extremely unstable, and conversion to 8-MHz crystals is a necessity. This means adding another tube on a sub-chassis as an electron-coupled oscillator, and converting the original oscillator to a doubler stage. Again, those of you with a good library of older *73 Magazines* are in good luck here, since Larry Levy and others wrote countless articles on how to modify a Sixer. The later HW-32As used an 8-MHz oscillator, so here it's just a simple rewire job. But, the Sixer receiver on FM? Well, if you must, but remember that they were barely marginal on AM.

The easiest FM conversions are to the Gonset Communicators. Here, there are two ways to go. If you have a matching Communicator vfo, you need only to plug in a mike and preamp. Or you can again rewire the existing transmit oscillator and screen-grid modulate it. Transmitter conversions in general are usually a matter of rerouting existing wiring. Receiver mods run the gamut from "use as they are and slope detect" to "crystal control and quad-detector installation." Here, the choice is yours.

With equipment costs as low as they are for old six-meter gear, we can afford to experiment to our hearts' content—kind of like the experimentation with 10-meter gear salvaged from the 11-meter CB service. The 11-to-10 and what is starting to happen on six meters are similar. The idea of getting back to low-cost basics. As my friend Bob Heil K9EID says in his new book about 10-meter FM, it's "putting the ham back into amateur radio." In fact, I am in the process of reading Bob's new book at this moment, and may have a review for you next month.

I guess the greatest joy I am getting out of all of this is the stir I seemed to have generated among the 10½-meter illegals. I am very proud to tell you that I have become a thorn in their side, and consider being hated by that crowd a position of honor in our society. The other evening I sat glued to my Realistic DX-160 as one of them read what he termed a "*73 Magazine* exposé" to his cronies, and then listened as this group of fanatics discussed ways to get even. Obviously, we amateurs are not the only ones who read *73*.

For those of you who may wonder if my divulging of what I have overheard is legal, well, Section 605 does not offer any form of protection to those who operate illegally, out-of-band, and unlicensed. And I do not worry about them either. Like those who harass two meters and other bands, their bark is greater than their bite. Remember, I am also a persona non grata among certain segments of the Los Angeles two-meter community, and consider this also something to be proud of. When I took to writing this column, I did not intend for it to become a popularity contest. I believe in calling things as I see them, and if certain elements of our society don't like it, such is life.

I'm not out to win any popularity contest, be it with the ARRL or anyone else. But, it's also the

same reason that I have waited a long time in some cases to report on some items, such as cases involving malicious interference. I have no intention of "trying cases in print." It's for the courts to make the legal decisions—we report. I know this is a bone of contention with some readers, but here in this nation, a person is considered innocent until proven otherwise. With the slow movement of the bureaucratic system, coupled with normal magazine lead time, it's sometimes months before you read something here that might appear in other news services sooner, though in far less detail.

But we are getting off the subject. The main thing I want to report is that people are coming to six meters little by little. They're discovering a whole new world in amateur radio. A world seemingly untouched by time. A place where they can still experiment, rag-chew, and enjoy a hobby, and do so with practically no monetary outlay. Eventually those who supply equipment for our service will catch on and start promoting new goodies, but in the meantime we can still sit back and enjoy what amateur radio is really all about. Six meters may be the band that time forgot, but, in retrospect, this may have been a blessing in disguise.

WESTLINK UPDATE DEPARTMENT

Another question that is often asked of me is why I continue to produce a weekly amateur radio newscast when there is no way to subsidize it. Actually, I am not the only one who subsidizes it, there are two of us. For the most part, the funding to keep the Westlink Amateur Radio News alive comes from Bill Orenstein KH6IAF and me. Currently, it costs us close to $500 each month, a cost that we share. And we cannot use Westlink as a tax deduction since it's not a charity, business, or any known category of business operation. It's simply the "free service" that its founder, Jim Hendershot WA6VQP, meant it to be and we intend to keep it that way. Every now and then we do receive a small donation but after doing the math out a few weeks ago, the results show that Bill and I fund over 97% of the operational costs.

Unlike other similar services, we do not solicit financial support and only accept that which is offered with no strings attached. It's this concept of total autonomy that has kept us from soliciting support from any organized group, Including the ARRL. It has also kept us from asking funding from the amateur manufacturers and publishers. One cannot be autonomous if one accepts the open support of industry or anyone else. So, we just continue as best we can. It's not ego. It may have been in the beginning, but spending 10 hours a week in producing a 10-minute newscast can become an ego buster really quickly. Yet, instead of falling apart, we are growing! And I think I know the reason.

Unlike anything else in amateur radio, save one's own private station, Westlink is the only entity of its type. First, it costs the amateur nothing but a phone call to get news about his hobby service, and another phone call by him may put him into the position of providing an important story to his peers. These days, better than half of our news stories are those which are phoned to us. True, the 10-minute time constraint of our format makes it impossible to use every story we receive, but, nonetheless, the input from the amateur community itself coupled with other standard news sources is what makes it really work. It adds up to about 10 hours each week, 52 weeks a year. We take no holidays.

The reason for bringing this all up at this time is to tell you about the latest expansion of the Westlink news service: A second automated number located in the Dayton, Ohio, area is intended to provide bulletin stations and visually handicapped amateurs in the eastern and central time zones with a more economic method of obtaining the weekly newscast. The people sponsoring the new automated newsfeed are the same people who put on the nation's largest amateur radio convention each year. I speak of the Dayton Amateur Radio Association and its current President, Vic Stauder WA2KOO/8.

The whole idea started over a late snack during the 1980 Hamvention and became a reality in late September of 1980 when the Dayton newsfeed went into full-time operation. Both the Los Angeles (213)-465-5550 and the Dayton (513)-275-9991 numbers carry the same information produced in the Los Angeles Westlink facilities. The new service was inaugurated with newscast number 156, the start of the 4th year of Westlink operation. Another change made was to make the dial-in numbers public. We realize that there will be some who may abuse the service as a result of this change, but we also feel that it is far more important to have the service available to all who may need it with as little effort in obtaining it as is possible.

So, to those who ask why people like Bill Orenstein, Alan Kaul W6RCL, Jim Davis KA6IUH, Lenore Jensen W6NAZ, Burt Hicks WB6MQV, and others far too numerous to mention devote their time and effort to something that has no monetary reward, I can only tell you that we do it because we love the Amateur Service, and if nothing else, it's our way of paying back a bit of the debt we each owe amateur radio for the many hours of enjoyment we have obtained from it.

Personally, I know that Westlink, this column, and everything else I do in the name of amateur radio will never begin to repay the debt I owe the hobby, a debt that goes back many years when it was my fellow hams who carried me through one of the worst times in my life.

FUN!

from page 22

5) Believe it or not, Hiram Percy Maxim wrote an autobiographical book about his experiences as a youngster, called *A Genius in the Family*. Later, it was adapted as a motion picture and retitled. What was the name of this movie, and who played HPM's parents?

1) "That Gang of Mine"—Leo Gorcey and Joyce Bryant.
2) "Black Like Me"—James Whitmore and Judy Canova.
3) "You for Me"—Peter Lawford and Jane Greer.
4) "So Goes My Love"—Don Ameche and Myrna Loy.

ELEMENT 4—TRUE-FALSE

		True	False
1)	The original Novice license restricted its holders to QSOs of ten minutes or less, and limited conversations to discussions of signal reports, names, QTHs, weather, and rigs.	____	____
2)	A technical editor of *QST* once electrocuted himself.	____	____
3)	Nikola Tesla, father of practical ac power, was deathly afraid of round objects (such as baseballs and pearls) and spent many years trying to invent a device that would photograph a person's thoughts from his retina.	____	____
4)	SSB was originally called SSSC.	____	____
5)	The first "W" calls were issued in 1929.	____	____
6)	Before 1950, you only had to confirm 80 countries to become a DXCC member.	____	____
7)	Major Edwin H. Armstrong, inventor of FM radio, committed suicide by leaping fom a 13th story window. He was despondent over the fact that commer-		

cial interests were using his invention without paying due compensation. ______ ______

8) ARRL Headquarters has two club stations, W1AW and W1INF. ______ ______

9) Before 1940, the continental code for a "period" was .. .. .., not today's . - . - . -. ______ ______

10) During the "atom scare" of the late 1950s, the FCC required amateurs to monitor a broadcast station while operating in case of an enemy attack. ______ ______

11) Louis Daguerre invented the resistor. ______ ______

12) The average spark transmitter used up to 18 tubes. ______ ______

13) The US Post Office issued an amateur radio commemorative stamp in 1952. ______ ______

14) In 1957, ARRL membership cost only $5.00. ______ ______

15) First marketed in 1946, Collins' KWM-1 was the world's first fully transistorized transceiver. ______ ______

Five Questions About Marconi

16) Marconi had only one eye. ______ ______

17) Marconi won a Nobel Prize for inventing radio. ______ ______

18) Marconi was a Fascist. ______ ______

19) Marconi was half-Irish. ______ ______

20) Marconi held the amateur callsign I2CC. ______ ______

ELEMENT 5—SCRAMBLED WORDS

Unscramble these names of men who made Amateur Radio possible.

zerht	atwt	soomli
atvlo	xiwemla	yfaaard
miteteszn	plopred	pamree
mroinac		

THE ANSWERS

Element 1:
See illustration 1A.

Element 2:
1-J, 2-P, 3-T, 4-S, 5-U, 6-H, 7-C, 8-E, 9-N, 10-F, 11-K, 12-A, 13-G, 14-L, 15-I, 16-R, 17-O, 18-M, 19-D, 20-Q.

Element 3:
1-1 Sort of makes you think that ham radio hasn't really come all that far in the past 60 years, doesn't it?
2-3 Named after GE's founder, this award was tossed on the scrap heap when the company ceased selling its products to amateurs.
3-1 DX clubs and foundations, prepare your spaceships!
4-2 But friends just called him Al.
5-4 I'll bet you wonder where I dig up this info. Never mind. Just let me know the next time it appears on the *Late Show*. Perhaps the ARRL should spring some loot for a print of this classic. Bet it would be a great draw at hamfests and conventions.

Element 4:
1 False—But it sounds like a typical Soviet QSO.
2 True—Ross Hull's last experiment in 1938 involved touching the high-voltage cage on an experimental TV.
3 True—He also thought you could beam electricity from satellites in orbit around the Earth. A "crazy" idea that may actually come true in the future.
4 True—"Single-sideband, suppressed carrier" was the original name.
5 True—Before then, things were pretty confusing when you had a 2XYZ in 40 different countries.
6 False—Eighty countries isn't a "century," is it?
7 True—Typical American "success" story.
8 True—It was abuses like this that led the FCC to eliminate all new club callsigns.
9 True—And the exclamation point was - - . . - - until the change.
10 True—It was hard trying to keep the music from going out over the air.
11 False—He invented photography.
12 False—Spark transmitters didn't use tubes, silly!
13 False—1964.
14 False—It was only $4.00.
15 False—That would have been a neat trick, considering that the transistor wasn't even invented until a few years later.
16 True—He lost his right eye, in 1910, in an auto accident.
17 True—A prize which he shared with radio's "co-inventor," Karl F. Braun. By the way, the unknown Braun was so amazed that he was chosen for the honor, he actually apologized to Marconi at the awards ceremony.
18 True—Politically naive, he was an early supporter of Mussolini's Blackshirts.
19 True—His mother was born in Ireland. Marconi's first wife was also Irish.
20 False—Marconi was never a licensed amateur.

Element 5:
(Reading from left to right) Hertz, Marconi, Loomis, Volta, Watt, Faraday, Steinmetz, Maxwell, Ampere, Doppler.

SCORING

Element 1:
Twenty points for the complete puzzle, or ½ point for each question correctly answered.

Element 2:
One point for each manufacturer/distributor you matched to its QTH.

Element 3:
Four points for each correct answer.

Element 4:
One point for each correct answer.

Element 5:
Two points for each name successfully unscrambled.

0-20 points—Novice school dropout
21-40 points—Vacuum resident
41-60 points—RCC member
61-80 points—Good memory
81-100+ points—Ham historian

W2NSD/1 NEVER SAY DIE

editorial by Wayne Green

from page 8

duce already invented and developed products more cheaply than other countries.

Further, I said that I felt that this was a perilous long-term course. Only by the development of their own electronic engineers and technicians will they be able to compete with Japan in technology. I then quoted the figures on hams in Japan... 500,000 active, and the US with perhaps 200,000 active. I further said that the technologies of all countries of the world are surprisingly proportional to their ham populations. Taiwan could hardly expect to compete with these other countries when it has but one single licensed radio amateur.

I told them that you get people interested in technical careers when they are teenagers and that these are the people who have always made the technology breakthroughs. Recognizing the security problem which is almost paranoic in Taiwan, I mentioned that amateur radio had been introduced in the country of Jordan right in the middle of their civil war and that no security problems had been encountered.

The Taiwan businessmen came up after the talk to thank me for it and say how much they appreciated me speaking out like that. One American was furious with me... a representative of the Electronic Industries Association (EIA) who felt that we should try to keep technology in the US and not encourage other countries to compete.

Two of the newspaper reporters present wanted copies of my talk to publish, so Sherry typed it up for them from her recording of my impromptu remarks. They also sent photographers to take pictures of me to go with the articles. Whether this will have any long-range effect or not remains to be seen.

To show that Japan is decidedly ahead of us in the development of electronics products, all I have to do is open my gadget bag which I cart around. Out comes a Sony TCS-300 stereo recorder, a Sony 400 micro-recorder, a Sharp Talking Clock, A Casio musical calculator or two... things like that. On my wrist is a Casio C-80 calculator watch which has replaced the Rolex I wore for many years. Sherry usually has her Sharp computer and cassette interface in her bag, along with her Sony recorder for program and data storage. This is the same unit Radio Shack is importing and selling as their TRS-80PC. With about twice the number of active hams in Japan, is it any wonder they are so far ahead of us in electronics technology?

My recent visit to Kenwood in Tokyo did not brighten my view of the prospects for American firms. I've seen nothing here to compare with the Kenwood development lab... and with the Yaesu lab which I visited last year. These labs are packed with hams, all having a ball designing next year's ham rigs.

JAPAN AND REPEATER JAMMING

Since repeaters are not yet permitted in Japan, what is the connection I'm trying to make? This one is a bit far afield, but perhaps you'll come with me and see some parallels. By the way, with regard to repeaters in Japan, the benefits of repeaters in other countries have not been entirely lost on the Japanese... it's just that their version of the FCC moves far more slowly than ours, though you may think that impossible.

Having recently wandered the streets of several Asian countries, often at night, and never once having to fear that I would be in trouble, I have been wondering about this. Why is it that women can walk alone at night in Tokyo with no worries? Why is it that I have no problems when I walk in even the seemingly worst parts of Hong Kong at night? Yet, there are many areas of New York City which are not even safe during the daytime?

One of the reasons why I deserted New York almost 20 years ago had to do with the deterioration of life there. Nowadays, when I do have to visit the city on business or for a show, I can feel the fear which grips New Yorkers as they plod through the subway stations or walk the streets... even the well-lighted streets... at night.

Another indication of the wide difference between the Asian cities and our U.S. cities is evidenced in the graffiti. This is just one clear evidence of resentment which is not well hidden... the growing hate of the government by the people. This manifests itself in incessant vandalism, where anything which can be destroyed usually is. You don't see this in Japan, Hong Kong, Taiwan, and Singapore.

Milton Friedman put his finger on this in a recent *Newsweek* column... and I think he is right. This vandalism and the growing crime are results of the frustrations people are having with government. The recent election results certainly showed that the frustration level is high. It makes sense to me.

Having recently read the William Simon paperback, *A Time For Truth*, an expose of the gradual encroachment upon us by our government... and having felt the helpless frustration of being in the clutches of that government myself... I am beginning to understand what has happened to our country... and to much of Europe, which has been going along with the same political tide. In the Asian countries which I have visited, the governments for the most part are not interfering with business and with the people... certainly not to the extent which we have developed.

Having been around since before these great changes started, back in the 30s, I've seen personally the enormous change which we have undergone in our country... and been frustrated by it. Much of this has been in reaction to the panic and depression of the 30s, yet we know now that that was brought about primarily by the actions of our government and was not a failure of business at all. Friedman, in his TV series, *A Time To Choose*, made this clear.

Hong Kong and Singapore are shining examples of what can result when the government does not try to shackle business and dominate the people. Both are centers of great industrial growth and wealth. Indeed, you see more Mercedes cars per block in these countries than anywhere else in the world I've visited. Yet this wealth is not gained from taking advantage of workers, who also are enjoying a level of living which is attracting people from all over the world.

One wonders what would happen to the spirit of our country if the government stopped trying to manage the economy and business... a sort of small-scale copy of the Russian management system, which has failed so monstrously. It does seem likely that our oil problems would be resolved in a free market... that businesses could save billions a year if they could stop having to fill out forms for the government. I know that even in a business as small as mine, we are spending an estimated $75,000 a year just in filling out forms for the government... gathering information that we have no need for ourselves and sending it in. That may not seem like much, but that's almost a dollar per subscriber for *73*.

It may be that Reagan will be able, as none before him has, to start cutting down on the government proliferation. Will they be able to get rid of the HEW? Of the ICC? OSHA? The Energy Department... and so on? And will that eventually bring about happier people and less crime? My end question... I wonder, if we are able to make these changes, if it will result in a spirit in our country which will still the jamming of repeaters, the cursing on the bands, and the general unhappiness which is being demonstrated on our ham bands?

We really don't have to just learn from our past, when we did not have the government bureaucrats all over us and things were happier... we can learn from the lessons of those few countries where there is freedom and they do show the same spirit I saw here when I was young... and which I think we can regain.

The people in Japan are happy and their subways clean. There is not one hint of the graffiti which covers every car and station in the New York subway system. In describing what I saw in a public toilet in the leading restaurant in Canton, China, I

was moved to compare it with the filth and smells of a toilet in a New York subway...only worse, if such is imaginable. Japan, though close to China, has nothing like that.

Several of the people on our visit to China described the frequent serving of tea as the Chinese water torture...since the use of any bathroom but that in our hotel was almost impossible for the women...and the tourist service kept us away from the hotel from early morning till very late at night.

OOPS, WE GOOFED AGAIN?

A few years ago, I ran an article in *73* by a chap who told about discovering the principle of the transistor back in the 1930s...the only problem was that he didn't recognize what he had discovered. Thus amateur radio managed to miss out on one of the most startling discoveries of history. Win a few, lose a few.

Some recent events lead me to wonder if we may not have managed to miss the boat again, though this time there is still an opportunity to pick up the marbles and claim ourselves winners.

Thirty years ago, when amateur radio was in a period of very rapid development using ideas left over from the War and catching up for the time lost from 1941-1945 when we were off the air, we saw the beginnings of VHF repeaters, the first single sideband rigs, and a brief experimentation with double sideband. But, let me explain some recent events so you'll see what I'm talking about.

My success in recording business meetings and symposiums with a miniature Sony TCM-600 cassette recorder was such that when the need arose for a second recorder for this purpose, nothing else was even considered. It is small, light, and amazingly sensitive, putting similarly sized recorders of other brands to shame. Fortunately for me ...and possibly for you...the local Sony dealer was out of TCM-600s when I wanted one.

A few days later, I saw an ad in *The New Yorker* for a Sony TCS-300, a miniature stereo cassette recorder. Having enjoyed the phenomenal reproduction of the Sony Walkman stereo cassette player, the idea of being able to make stereo recordings with something not much larger than the player was attractive. And the ad pointed out that a stereo recording of a meeting made it possible to sort out the various voices talking with ease, while a mono recorder mixed them all together. Definitely a plus.

Despite the full-page ads for the new recorder, Sony had no TCS-300 recorders available when I called. Okay, I'd be in Tokyo in a few days and I'd get one there. Sure enough, I checked with the Sony store in Tokyo and was able to get a 300 immediately. Further, the price was $130 instead of the U.S. price of $220—a plus. I'd brought along my Walkman Sony and some music tapes, so I checked them out on the 300 and found it as fantastic on music as the Walkman...though a bit more bulky to carry.

As a side note, the Sony Walkman has been such a hit worldwide that I saw imitations of it at all of the consumer electronic shows...in Tokyo, Seoul, Taipei, and Hong Kong. They all seemed to be good buys and less expensive than the Sony. Once you hear one of these tiny stereo cassette players, you almost have to have one. I use one while I walk, to make the time pass better on plane trips, and even while skiing.

On the Asian trip, I began to use the 300 to make recordings during some of the dinners. When I checked the recordings, I was surprised to find that I could indeed hear what everyone around the table was saying, despite the high level of din from surrounding tables. Most Chinese meals call for ten people to a table, so there are two to five simultaneous conversations going on. With the stereo I could "tune in" with my mind and listen to any of them.

This brought to mind a letter to the editor in one of the ham magazines back in the early 50s. It had to do with using the General Electric Signal Splitter, with one earphone connected to the upper sideband output and the other to the lower sideband. The letter reported that using this system it was possible to tune in one double sideband signal and hear it much more clearly than with ordinary monophonic reception. I tried the idea at the time and found that the writer was right—the result was a very easy to copy phone signal which could be heard clearly through considerable interference.

The next idea came quickly ...what would happen if we were to use stereo microphones on our double sideband transmitter and separate channels into stereo earphones for reception? I suspect that the result would be much the same as listening to the individuals around the table amid the babble in the background...something which completely ruins monophonic recordings.

Would it be possible to use stereo DSB on the ham bands? With such a system, would it be possible for us to operate with stations every few Hertz up and down the band? I suspect that this might well be so. We know that monophonic double sideband signals with a synchronous detector can give good results with very narrow channel spacing. Using the human brain for the filter we should be able to get even better operation since no filter has ever even come close to the ability of the brain to do this kind of work.

The ball is in your court. There is the idea...now it is up to you to do the experimentation and development. Will it be possible for phone stations to operate at a density of perhaps 50 times that presently possible using single sideband...and with far less interference? I suspect this may be true. If it is, we may have another amateur radio breakthrough in communications techniques. You may be sure that I'm interested in getting articles for *73* on your experimental work ...and the results.

As I've written recently, the possibilities for DSB seem greater than those for SSB and one is led to wonder what might have happened in history if General Electric had supported John Costas and his DSB work as well as Art Collins did single sideband. Amateurs who were active on the DX bands in the 50s remember the many experimental flights of SAC planes with Collins sideband gear aboard. I remember Mort Kahn W2KR and Don Merten W2UOL (also K2AAA) and their efforts to promote SSB for Collins. I don't know how much they got out of their work, but I know Mort would be unlikely to work that hard for much less than millions. Since billions were at stake, a few million would have been a small investment.

It thus turns out that Kahn has had a substantial impact on amateur radio...and the world, for that matter. He originally owned Tempco, a firm making transmitters, but which he sold to Otis Elevator. Kahn retired to his yacht with several million dollars from the sale, as I understand the story. The SSB coup did not hurt his fortunes and I think got him interested in taking over the ARRL, which he did almost singlehandedly during the early 60s.

I've already reported on how Kahn managed to get elected to the ARRL and how he quickly took over running the organization. I've also covered how he engineered the move toward a return to the Class A and B licensing which stopped U.S. ham growth for over ten years and set up Japan to surpass us in technology in the 1980s.

If DSB/stereo turns out to be as efficient a communications medium as it appears, we may find that Kahn, by masterminding the sales pitch for Art Collins on SSB, did it to us again.

HORIZONS' FALL

Ham Radio Horizons, which was started in early 1977... about the same time that I started *Kilobaud MICROCOMPUTING*...and reached its peak about a year later when we had a fair number of new hams in need of the simplified articles they presented, finally threw in the towel. With the number of ad pages shrinking constantly, the magazine was losing money every month. A last-ditch effort to rescue it by changing it from a Novice magazine into another *Ham Radio* was doomed to failure.

Ham Radio itself seems to be going the same route, with the average number of ad pages dropping off. In 1977 they had 66 pages average...in 1978 there were 65 pages. By 1979 it was down to 54 pages. This year the average is down to under 35 pages of ads per month! That's obviously a catastrophe.

Part of this has been due to the competition with *73*, where most authors are aware of the better payment they get for articles in the larger circulation magazine, thus bringing the best articles first to *73*. Part has been due to the drop in interest in amateur radio in general... reflected in a particular drop in esoteric, high-technology articles. Part has been due to the

troubles between the top management of the magazine, now resolved with the death of Jim Fisk, which was reflected in the magazine content. Part was the result of the gathering depression on everyone at the publication over the failure of *Horizons* and the panic over the failure of *Ham Radio* to cope with the changing market.

These are generally hard days for the starting of new magazines. Much of the economy is hurting. Even computer magazines have been more characterized by failure than success. We've seen *Microtrek* and *ROM* give it a big try, only to fail. We've seen *Personal Computing* magazine stagger alone, losing money for several years before throwing in the towel and giving up (it's now in the hands of Hayden Publishing, who is going to have a try at it). One of the worst debacles in the computer field has been the *Byte* offspring, *onComputing*...a total disaster. Despite incredible investments in circulation ads, the magazine has brought little more than laughs to the industry.

Our *MICROCOMPUTING* and *80-MICROCOMPUTING* magazines showed that it was not the market, only the understanding of the market that was responsible for the success or failure of a magazine. *80-MICROCOMPUTING* has been one of the most successful high-technology publications in the history of publishing.

Frankly, though the failure of *Horizons* came as no surprise, we were really expecting *CQ* to go down for the final count first. Cowan ran it into the ground before turning it over to the new crew. Despite major efforts at bringing it back to life, neither circulation nor advertising has seemed to really respond. The pages of ads have dropped from 40 average in 1979 to 36 in 1980. With the ham market continuing to drop off, the going is getting tougher for all ham magazines...and the weaker can be expected to go under. Even *QST* has been dropping...from 107 pages average in 1979 to 95 in 1980. *73* dropped a little, about 2½ pages average, running now about even with *QST*.

What will 1981 bring? Unless amateurs are able to get the hobby going again, there are going to be fewer magazines... and fewer sources of information.

THE NEW ENGLAND CONVENTION

Though I was in Tokyo at the time of the show, some spies have reported on the Boxborough ARRL convention. It appears that a fair crowd turned out for Saturday, but it was virtually deserted on Sunday. There is considerable difference of opinion on the actual number of attendees, with exhibitors putting it at around 3,500 and management at 4,500 or so. Judging from the response at the *73* booth, even the 3,500 figure is generous.

There were only two dealers at the show exhibiting...Tufts and Harrison Radio. Harrison, which seems to be in trouble these days, had little merchandise, but was promising shipment. With all but one of their stores closed and a lot of rumors flying, it was good to see that there was some life left. Tufts, which had piles of equipment available, racked up record sales for a convention.

The *73* booth kept active all through the convention, but some of the other magazines folded up early due to inactivity. *CQ* apparently has yet to win over many amateurs with their "new" format...which looks amazingly like the one which sunk it for Cowan. *HR* and *HRH*, with the loss of Fisk, seem to have lost direction and the resulting boredom with the publications was evident at the convention.

The hit of the show was a new slow-scan system from KW Control Systems. This new system provided virtually 500-line resolution pictures and had just about everything you could ask. Kenwood was there with their new equipment and that certainly got the blood going. Ditto the new Icom gear. Yaesu seems to have lost enthusiasm and was not present...nor was Den-Tron. There are rumors of a change in management at Den-Tron, with emphasis on non-ham equipment.

The Avanti and Kantronics booths were packed all through the show, as was the Optoelectronics booth. The convention was definitely worthwhile for the attendees...and for the exhibitors...no matter the actual attendance numbers.

RADAR DETECTOR PRECEDENT

The state of Connecticut was recently backed down by the courts and prohibited from confiscating radar detectors. Since this decision came from the Appeals Court, it will act as a precedent for other courts. The court also affirmed the right to a jury trial for radar detector defendants, which should further discourage that state from harassing detector users.

I WANT *YOU!*

With most magazines, your responsibility as a reader ends once you have subscribed or bought a single copy. This is not true with *73*. When you decide to read *73*, you are committing yourself to much more. I expect you to do your part toward making the magazine interesting and to accept some responsibility for this.

For instance, one of the reasons you enjoy *73* is because we have the newest in state-of-the-art articles. In fact, many professionals write to say that they are able to find out far more about new ideas by reading *73* than by reading the dry papers in the professional journals. You can help with this by keeping your eyes open for any friend who has done something or built something which we all should know about. For some reason, those who do the most brilliant work are usually least interested in doing the paperwork, so they need to have you lean on them.

You should be aware of one other factor: The more readers we have, the more advertisers we will have...and the more pages of articles we will be able to publish. So see that everyone in your ham club knows about *73*, spread the word at work, and help us to grow.

You can help me get information, too. Though I breeze through some 200 magazines a month, with several thousand out there I don't see, it is very likely that I am missing a lot of things which I should know about. So, if you run into something which you think might be of interest to me, please cut it out or make a copy and send it so I can read it. I'm interested in many things...anything on hamming, radar detectors, UFOs, Jordan, getting the US going again, microcomputers, etc.

Each month I read *Car and Driver* magazine with envy... noting their many interesting editorials. I do wish that more readers with interesting ideas and experiences would write in. With the color we are able to use in the magazine these days, we can do a much better job on DXpedition reports. So keep those cards and letters coming.

HAM HELP

I wish to convert a Lafayette model HB-740 CB rig to 10 meters. I need a schematic for this rig since Lafayette has gone out of business. Any hints or suggestions for converting the HB-740 to 10 meters will be greatly appreciated. I'll be glad to pay all costs.

Chris Van Veen N1AUD

I am in need of an ac power supply for a Collins KWM-2A.

H. F. Schnur
115 Intercept Ave.
N. Charleston SC 29405

I have a James Thomas HCV-3KB-1 keyboard for SSTV. I would like to hear from anyone who knows of a successful way to superimpose lettering over other video SSTV pictures generated by the Robot 400 scan converter. I'm also looking for any information on the RTTY and CW add-on boards for the HCV-3KB-1.

Any and all information and/or ideas would be greatly appreciated and passed on to other James Thomas owners. Thank you.

Michael Larson WD0EZK

CONTESTS

from page 14

ble on 160-meter phone in a maximum of 30 hours allowable contest time. Multi-operator stations may operate the entire 48-hour contest period. Entry categories include single- and multi-operator, both with single transmitter on phone only.

EXCHANGE:

Stations within the Continental USA and Canada transmit RS report and state or province. All others transmit RS report and DX country.

SCORING:

All valid two-way contacts score 5 points per QSO. A station may be worked only once for contest credit! Multipliers are as follows: 1 multiplier point for each of the Continental US states (48 max.); 1 multiplier point for each of the Canadian provinces (13 max.); 3 multiplier points for each DX country outside the Continental US and Canada.
The final score is the total QSO points times the total multiplier points.

DX WINDOW:

Stations are expected to observe the DX window from 1.825 to 1.830 MHz as mutually agreed by Top Band operators. Stations in the US and Canada are asked not to transmit in this 5-kHz segment of the band.

AWARDS:

Contest awards will be issued in each award category in each of the Continental US states, each Canadian province, and each DX country.

DISQUALIFICATIONS:

Disqualifications may result if contestant omits any required entry forms, operates in excess of legal power authorized for his given area, manipulates operating times to achieve a score advantage, or fails to omit duplicate contacts which reduce the overall score more than 2%.

ENTRIES:

Each entry must include log sheet, dupe sheet for 100 or more contacts, a contest summary sheet, and a multiplier checklist. All entries must be postmarked no later than February 21st. To request contest forms or submit your entry, write: Dan Murphy WA2GZB, PO Box 195, Andover NJ 07821 USA. Please include an SASE!

FREEZE YOUR ARCTIC OFF EXPEDITION

Starts: 2000 GMT January 17
Ends: 1500 GMT January 18

The Ford Tin Lizzy Club's North Metro Chapter will endure their third expedition out on the frozen wastes of Lake Saint Clair. Operating frequencies will be 7275, 21380, 146.52, 146.55, and 146.58, as propagation allows. One station will always be active on 7275! The callsign is AD8R/8 and, as usual, a handsome certificate will be awarded to all contacts. QSL to Box 545, Sterling Heights MI 48078. No SASE is needed!

MICHIGAN QRP CLUB CW CONTEST

Starts: 1500 GMT January 17
Ends: 1500 GMT January 18

This is a CW-only allband (160-10 meters) QRP contest in conjunction with the dates of the AGCW-DL QRP contest. This contest is open to all amateurs and all are eligible for the awards. Each station will be competing within own state, province, or country in the three categories listed: (1) one Watt or less of output power; (2) five Watts or less of output power; (3) over five Watts of output power. A station may be worked only once per band for point credit.

EXCHANGE:

RST, QSO number, and power output.

SCORING:

Each contact is worth one point.

AWARDS:

Certificates awarded to the highest-scoring station in each state, province, and country.

ENTRIES:

Log information must include full log data, name, address, equipment used, and power output. Logs must be received by the contest manager no later than 6 weeks after the end of the contest. US and Canadian entries please include an SASE. All others please include one IRC for contest results. Send all logs to: Contest Manager, Michigan QRP Club, 281 Crescent Drive, Portland MI 48875.

QRP ARCI JANUARY SSB PARTY

Starts: 2000 GMT January 17
Ends: 0200 GMT January 19

The contest is open to all amateurs and all are eligible for the awards. Stations may be worked once per band for QSO and multiplier credits. No repeater contacts are allowed. VHF/UHF contacts must be direct.

EXCHANGE:

Members—RS, state/province/country, and QRP number. Non-members—RS, state/province/country, and power input.

SCORING:

Each member QSO counts 3 points. Non-member QSOs are 2 points, and stations other than W/VE count 4 points each. Multipliers are as follows: more than 100 Watts input—×1; 25.1-100 Watts input—×1.5; 5.1-25 Watts input—×2; 1.1-5 Watts input—×3; less than 1 Watt input—×5.
Final score is total QSO points times total number of states/provinces/countries per band times the power multiplier. Any bonus points are then added to the final score. Stations powered by solar or wind power can add 300 bonus points. Stations powered by other emergency-type power (batteries, generator, etc.) can add 100 bonus points.

FREQUENCIES:

SSB—1810, 3985, 7285, 14285, 21385, 28885, 50385.

AWARDS:

Certificates to the highest-scoring station in each state, province, or country with more than two entries.

LOGS & ENTRIES:

Send full log data, including full name, address, and bands used, plus equipment, antennas, power used, and method used for determining bonus points. Members should include their QRP number on the summary sheet with the scoring. Entrants desiring results sheet and scores, please enclose a business-size envelope with sufficient return postage. Logs must be received by March 25th to qualify. Logs arriving after this date will be used as check logs. Finally, in case of disputes with scoring, the decision of the contest chairman shall be irrevocable. Send all logs and data to: QRP ARCI Contest Chairman, Edwin R. Lappi WD4LOO, 203 Lynn Drive, Carrboro NC 27510.

FRACAP WORLDWIDE CONTEST

Starts: 0000 GMT January 18
Ends: 2400 GMT January 18

Use all bands, 10 through 160 meters, on SSB only. Operating categories include single-operator, one band, and all bands.

EXCHANGE:

RS report plus a three-figure contact number starting with 001.

SCORING:

Stations in FRACAP: Each contact with another FRACAP country counts 3 points; others count 1 point.
Stations in the rest of the world: Each contact with a FRACAP country counts 5 points; others count 1 point.
The multiplier is the total number of FRACAP countries plus all call areas in the 6 FRACAP countries worked. Final score is then the total QSO points times the sum of the multipliers.

AWARDS:

Certificates to all stations with at least 20 contacts with FRACAP countries. Plaque for the first-place station in each FRACAP country in each category, and for the winner outside FRACAP. Other awards according to participation.

ENTRIES:

Entries must be postmarked no later than February 28th and addressed to: PO Box 2412, San Jose, Costa Rica, C.A. For additional information, write to the same QTH.

TEXAS QSO PARTY

Starts: 0000 GMT January 24
Ends: 2400 GMT January 25

Sponsored by the West Texas Amateur Radio Club of Odessa TX. Use all bands and modes.

Each station may be worked on each band and each mode. Mobiles may be worked again upon each county change.

EXCHANGE:

QSO number (beginning with 001) and state, province, country, or Texas county.

FREQUENCIES:

Novice—3710, 7110, 21110, 28110.
Phone—3940, 7260, 14280, 21370, 28600.
CW—3575, 7055, 14070, 21070, 28090.

SCORING:

All non-Texas stations score points as follows: Phone contact with fixed station in TX = 1 point; CW contact with fixed station in TX = 2 points; phone contact with mobile station in TX = 5 points; CW contact with mobile station in TX = 7 points. Multiply by the number of Texas counties worked (254 max).

All Texas stations score 1 point per contact on phone, 2 points on CW regardless of fixed or mobile. Multiply by the number of state, countries, and Canadian provinces worked.

AWARDS:

Plaques to top scores: US, US Novice, DX, Canada, Texas fixed, Texas mobile, Texas Novice. Certificates to top score in each state, country, and province. Special awards as activity dictates.

ENTRIES:

All logs must be received by March 15th. Mail entries to: Tom Horton K5IID, 2708 Halifax, Odessa TX 79762.

SNOWFLAKE MADNESS

The Michigan Technological University Amateur Radio Club and the Copper Country Radio Amateur Association announce a radio celebration of our Winter Carnival festivities in the northernmost part of Michigan's Upper Peninsula.

Tech's Winter Carnival is probably the most spectacular winter festival in America with fantastic snow sculptures, dog-sled races, lots of skiing, and other festive events.

In association with the Copper Country Chamber of Commerce, we are issuing a certificate to all amateurs who make contact with any ham in the Copper Country between 0000Z February 2 and 0000Z February 9. Only one contact is required for the certificate.

Suggested frequencies are: 3.705, 3.975, 7.085, 7.105, 7.285, 14.085, 14.305, 21.085, 21.185, 21.385, 28.185, and 28.685. On CW, listen for "CQ Winter Carnival."

Send your QSL along with two 15¢ stamps (for postage and handling) to: Debbie Nietzke WD8JPX, 2005D Woodmar Dr., Houghton MI 49931.

from page 35

The SC-422 is housed in a 12- × 4- × 7-inch aluminum cabinet. The US distributor for the SC-422 is *KW Control Systems, Inc., Box 114C, RD#4 South Plank Road, Middletown NY 10940.* Reader Service number 479.

1750-METER TRANSMITTER

Palomar Engineers has announced a new transmitter kit for the 160-190-kHz experimenters' band. Operation at one Watt input power and with a 50-foot maximum antenna length is permitted by the FCC with no license required.

The transmitter is in two parts. The main transmitter assembly and wiring (including winding the Litz wire coils) is factory-completed. Wiring of the kit takes about an hour with simple tools. Complete assembly and operating instructions are supplied. The transmitter is for CW operation but easily can be AM-modulated if desired. For further information, contact *Palomar Engineers, Box 455, Escondido CA 92025.*

Palomar Engineers' 1750m transmitter.

NEW NLS TOUCH TEST 20 DMM

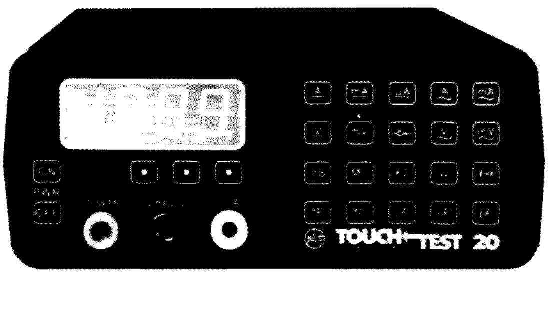
Futuristic touch controls and a multitude of test functions are featured in Non-Linear Systems' new Touch Test 20 digital multimeter.

The 3½-digit Touch Test 20 measures 10 parameters and 20 functions and includes 44 ranges. Test parameters include ac and dc volts, ac and dc current, resistance, capacitance, temperature, continuity, conductance, and diode test. The package size is a small 2.9 inches high by 6.4 inches wide by 8 inches deep. Weight is less than 3 pounds. Touch Test 20 may be purchased as a line powered unit or (optionally) comes equipped with rechargeable batteries for battery or line operation.

Accessories included with the instrument are OSHA-style test leads, a temperature probe, and a component test adapter for radial lead components.

An optional leather carrying case allows the Touch Test 20 to be operated while worn around the neck or on the belt, providing hands-free operation.

For further information, contact *Non-Linear Systems, Inc., PO Box N, Del Mar CA 92014; (714)-755-1134.* Reader Service number 481.



NLS's Touch Test 20.

REVIEW

from page 39

only this time you hold down the "6" button. When you think about it, this is pretty much the same way that a traditional keyer is adjusted, except that AEA has taken out the knob-twiddling.

If variable speed doesn't suit your taste, the CK-1 offers two preset speeds as well. You simply press the " * " button twice, and then press the "8". Following that, you enter the exact speed you desire. If that happens to be, say, 15 wpm, you press the "1" and then the "5". Presto! You're now operating at exactly 15 wpm. And just in case there is another CW fan in the family, you can preset another speed in the same manner, this time using the "9" key instead of the "8". Either memory can then be recalled. In either the variable mode or the preset, you can select speeds from 2 wpm all the way up to 99 wpm.

Well, so far we've discussed a lot of interesting features, but nothing of exceptional interest. Don't worry, it gets better! When AEA called this a memory keyer, they weren't joking. The CK-1 has a total capacity of about 500 characters, and this capacity is soft-partitioned, allowing you to divide the memories into up to ten messages of any length as long as the total does not exceed the storage capacity. If you want to put 400 characters in memory location "1" and 50 characters each in memory locations "2" and "3", it's perfectly possible. 50 characters in each of the ten memories? Fine. There aren't too many keyers that offer this flexibility. No matter how you juggle those memories, five hundred characters is a lot of memory. Get out your calculator and figure out how long it would take to send that at your usual speed, and you'll see what I mean. You'll have a blast loading it up with all the name, QTH, rig, and antenna information you can think of—and there still will be room for more!

"Aha," you say. "How hard is it to load?" Loading the memories couldn't be easier. Select the memory-load mode with the switch on the side of the keyer, push any button "1" through "0" to select a memory location, and start sending. This loading mode has automatic character- and word-space loading. If you pause for a normal word space or longer between characters, it will insert a normal word space in the memory and no more, so you can sit and think about what you are going to say next without filling up your memory with empty space. This provides a distinct advantage over most keyers that limit you to a real-time method of loading memory.

Admittedly, it sometimes is useful to be able to load in real time. For instance, if you are going to make a sally into the Novice bands, you may want to send at about 18 wpm but space your characters and words out so that actually you are sending at 10 wpm. Surprise! The CK-1 can do this, too. Just remember that like any real-time loading keyer, it then will eat up your available memory a lot quicker than if you send with "correct" spacing.

As you contemplate filling up that vast memory with seamless CW, the awful specter of *mistakes* rears its ugly head. Don't fret; the CK-1 has full editing capability, so when you err, you won't have to start all over again. If you get completely fed up with a particular message, it is a simple matter to erase the whole thing. You just press the memory location number (say "2") and the " * ". Whatever was in location "2" is gone forever. Naturally, if you shut the keyer off completely, *everything* goes. It is more blessed to leave the CK-1 on all the time than to reload its memories every time you operate.

By now, all the CW contesters are jumping up and down and yelling, "But does it do serial numbers?" Suffice it to say that the CK-1 will send and automatically increment any numbers between 01 and 9999, starting with the number of your choice. If you work more than 9999 stations in any single contest, you are either cheating or hallucinating.

There are a lot more things that the CK-1 can do, but I think I'll leave you to discover them on your own. All in all, I have only one complaint regarding the CK-1, and this involves the audio confirmation it gives you on each entry. I think this is a wonderful idea, but for various reasons I prefer to use the sidetone in the transceiver rather than the sidetone in the keyer. When you turn down the sidetone on the keyer, you lose the audio confirmation feature. Perhaps AEA could provide the option of having audio confirmation without the sidetone. This is, or course, a very small complaint, particularly in light of the fact that the CK-1 provides an excellent tactile response to each entry.

A commonly asked question is, "How do you remember which buttons to push?" I must confess that I was a little worried about this at first, but after about an hour with the thing I found myself handling the touchpad automatically. It's as though the keyer becomes an extension of your mind, and you suddenly realize that you are making it do what you want it to, without even thinking about it. I can't tell you exactly why, but the touchpad entry is much easier to handle than the knobs and switches on more traditional keyers. If you do forget how to make the keyer perform a particular function, you can simply refer to the clear and straightforward chart that AEA provides on the back of the instruction book.

Perhaps the most amazing thing about the CK-1 is its price. At the time of this writing, the list price is $129.95. A memory keyer with the features of the CK-1 can be a very useful tool for the CW operator; at the price, a lot of hams will be able to afford one. The CK-1 may well become the standard against which all other keyers are measured.

For further information, contact *Advanced Electronic Applications, Inc., PO Box 2160, Bldg. O & P, 2006-196th SW, Lynwood WA 98036; (206)-775-7373/524-7374.*

KRECO MODEL CO2A COAXIAL ANTENNA

When hams decide to put up a base station antenna for two meters, thoughts often turn to the ubiquitous quarter-wave ground plane. The usual approach is to mangle some coat hangers and solder the results to an SO-239 chassis-mount connector. This might be the cheapest solution, but it is not necessarily the best. This configuration has a relatively high angle of radiation and is not what could be referred to as a neighbor-pleasing design. Worse, the antenna-to-coax connection is exposed to nature; if your area receives a lot of precipitation, all you can do is buy lots of plastic tape and hope for the best.

The Kreco coaxial antenna makes up for all these deficiencies, and more. As suggested by its name, this antenna uses the coaxial method of achieving a ground plane. Instead of radials, a sleeve or skirt made of aluminum is connected to the shield of your 50-Ohm coax. The sleeve fits over the support pipe, and attaches to the antenna with a reassuringly large number of hefty sheet metal screws.

All this provides several advantages over the mangled-coat-hanger approach. The angle of radiation is lowered somewhat, and the coax feedline is effectively decoupled from the antenna, allowing your transmitter's power to be put to work where it will do the most good. Best of all, since the sleeve completely covers the coax connection, you don't have to worry about water getting into your expensive coax. Finally, the whole thing screws securely onto a 3/4-inch threaded pipe. If the pipe is well supported, the Kreco antenna will survive anything short of a tornado.

So how does it work? Very well indeed. Kreco makes no claims for spectacular gain; what they offer is good basic performance in a sleek package that can be put up and left up for years and never require attention. I'll never mangle another coat hanger again!

For further information, contact *Herb Kreckman Company, Cresco PA 18326.* Reader Service number 478.

I'm sure that hams could come up with some pretty good ideas.

Mike Desharnais WA1IPD
Somersworth NH

IT'S YOUR FAULT

Some observations: *73 Magazine* is the only ham radio magazine that I have subscribed to since 1963. Before then, I was an ardent supporter of *QST*, but when they got whole-hawg behind this incentive licensing and helped snatch away privileges I had earned fair and square and enjoyed for ten years, then the hell with them. They couldn't *pay* me to become an ARRL member—now or ever!

I don't go out of my way to bad-mouth the ARRL, but I don't hesitate to voice my own opinions on the air when asked, either. My philosophy has always been "the first time they do it to you is their fault, but if you go back for more and they do it to you again, then it's *your* fault!"

If anyone can show me where the incentive licensing change of 1968 helped amateur radio more than it devastated it, then I'll be the first to back-paddle, but first I'll need a satisfactory answer to why today—twelve years afterward—one must tune and search across the Advanced- and Extra-class portions of the bands, especially 40 and 75 meters, to find a QSO in progress while the General part is overflowing with nets and, yes, Advanced- and Extra-class hams, all bitching about the QRM!

Oh, I know the theory behind incentive licensing—everyone does. But it hasn't really worked out, has it? The way I see it, about all it accomplished was to crowd all the activity into the upper ends of the phone bands and leave the lower ends sparsely used. And this in present-day overcrowded bands! Well, there! That's off my chest. Oh, I don't expect it to do a bit of good, but it helps to relieve the pressure inside. Thanks for listening.

Bill Skipper K0ARG
Greeley CO

THANK YOU, DICK

I have enjoyed your magazine for several years but best of all was the article on Dick Bash. It gave me the idea to upgrade to Advanced, so I sat down and ordered the "Bash cheat sheet."

I want to tell you that the Final Exam is not something to "just memorize." I followed his advice and read the guide over 10 times, but, when I came to a question that I didn't understand, I would look it up in other books.

By the time I had finished the guide, I had read many articles pertaining to electronics. When I did go to the FCC to take the test, I actually knew much more than when I started the Bash system. I also found one question in the FCC test that was exactly as Bash stated it would be. But, I knew enough to pass with flying colors.

Thanks to Dick Bash and the Final Exam, I got the shot in my arm to get off my duff and study enough to pass one more exam. Now I am looking forward to sending for the *Final Exam* for Extra and trying to upgrade for the final time.

Thank you, Mr. Bash, for not giving me anything except the incentive to learn something.

Leo Mercer N0AHH
Albert Lea MN

AWARDS

from page 16

There are no band or mode restrictions; however, I am told if the applicant wishes to be recognized for single band or mode accomplishments, the preference should be stated when making application.

The Onion Award is issued on a point basis. Stations in Belgium need to total 10 points for the award; Europeans need 5 points; other DX stations must accumulate a total of 3 points. These points are earned as follows: one (1) point for a contact with an amateur located in the Aalst section of Belgium and two (2) points for a club station within Aalst.

To apply, have your list verified by two amateurs or a local radio club official. Enclose your confirmed list with 10 IRCs and send to: Onion Award Manager, Beulens Annemie, Ravenakkerstraat 52, 9390 Moorsel, Aalst, Belgium.

Stations which qualify for points are: ON1CH, ON1JA, ON1MC, ON1MV, ON1MW, ON4JT, ON4MS, ON4NJ, ON5HZ, ON5KC, ON5NM, ON5QT, ON5SU, ON5VP, ON5VW, ON6AZ, ON6BA, ON6BN, ON6BP, ON6CW, ON6EE, ON6ED, ON6EJ, ON6HW, ON6HX, ON6IR, ON6NN, ON6NV, ON6OX, ON6PZ, ON6RK, ON6SM, ON6VW, ON6WA, ON6WS, ON6YZ.

WAC YL AWARD

The Young Ladies Radio League issues the Worked All Continent Young Ladies Award to any licensed amateur who can meet the requirements of their program.

Two-way communications must be established with Young Lady amateurs in each of the six continents of the world: North America, South America, Europe, Asia, Africa, and Oceania. The applicant may utilize any band or mode of operation; however, crossband contacts will not be valid. There is no date limitation.

While all contacts with the six continents must have been made with duly licensed women operators, your contacts must have been made from the same QTH or community not to exceed a 25-mile radius.

To apply, applicant must prepare a list of contacts and also submit QSL cards or written proof of each contact along with the application.

While there is no charge for the award, applicants are requested to forward sufficient postage to cover first class return of your QSL cards. The YL Radio League assumes no responsibility for damaged or lost cards.

Forward your applications to the Award Custodian: Miriam Blackburn W3UUG, Box 2, Ingomar PA 15127.

While on the subject of YL awards, the YL Radio League also sponsors a Worked All States effort as well.

WORKED ALL STATES—YL

If you thought for one minute that the Worked All USA Award was fairly simple, try your luck at working each state with a YL contact! Not so easy, is it?

The Young Ladies Radio League makes available the WAS-YL Award to any licensed amateur who can establish two-way contact with a YL in each of the 50 US states.

While there are no date, band, or mode restrictions, you can request single band or mode recognition at the time application is made.

To qualify, all contacts must have been made within 25 miles of your QTH and any call you possess may be used to make contact with the 50 state YLs.

To apply, place your contacts in order by state beginning with Alabama and working alphabetically through your list. Include QSL cards or other forms of written confirmation for each contact claimed.

Forward your QSL cards, your application, and the list of claimed contacts to: Stella McPherson WA4WPN, 2029 Elbow Road, Chesapeake VA 23320. Be sure to include sufficient postage for first class mail return of your QSL cards. While there is no award fee, the League will not assume responsibility for the loss or damage of your cards.

WORKED ALL TRANSKEI

Early this week I received a very nice letter from Len S8AAT and he told of the very popular

Transkei Amateur Radio League Award now being offered.

The Transkei Amateur Radio League has formally announced the Worked All Transkei Award hich is made available to licensed amateurs throughout the world.

To qualify for the award, stations within Zone 38 must log a total of 4 Transkei (S8 prefix) stations since October 26, 1976. Stations outside of Zone 38 need only log two stations in Transkei.

There are no restrictions on bands or modes and even crossband contacts are permitted. Stations wishing to be recognized for single band or mode achievements may request recognition at the time application is made.

To apply for this award, prepare a list of claimed contacts and have it verified by at least two fellow amateurs or a local radio club official. Forward this list and an award fee of $1.00 or 10 IRCs to: The Transkei Amateur Radio League, PO Box 750, UMTATA, Republic of Transkei, South African Coast.

DIPLOMA DOS CONCELHOS PORTUGUESES

Sponsored by Associacao de Radioamadores Portugueses, this Portuguese County Award is available to licensed amateurs of the world under the following rules and conditions.

First of all, the DCP (Diploma of Portuguese Counties) is issued in four (4) classes: Class A —fixed HF; Class B—HF mobile; Class C—fixed VHF; Class D—VHF mobile. According to the number of Portuguese counties confirmed, the applicant may achieve one of the following grades of award: Grade I—75 counties; Grade II—125 counties; Grade III—175 counties; Grade IV—200 counties; Grade V—255 counties; Grade VI—250 counties; Grade VII—the maximum of 274 counties.

When making application for the DCP Award, the applicant is advised first to obtain the special awards booklet available from WB9RLY, who is the Canadian and US associate of the Amateur Radio Club of Portugal. This booklet will be extremely helpful to the applicant in establishing county locations and for finally submitting his or her application.

Do not send QSL cards! Have your list of confirmed contacts verified by at least two fellow amateurs or a local radio club secretary. Forward your application and an award fee of $2.50 or 7 IRCs to: ARP, PO Box 2145, 4021 Porto Codex, Portugal.

RCCI DX AWARD

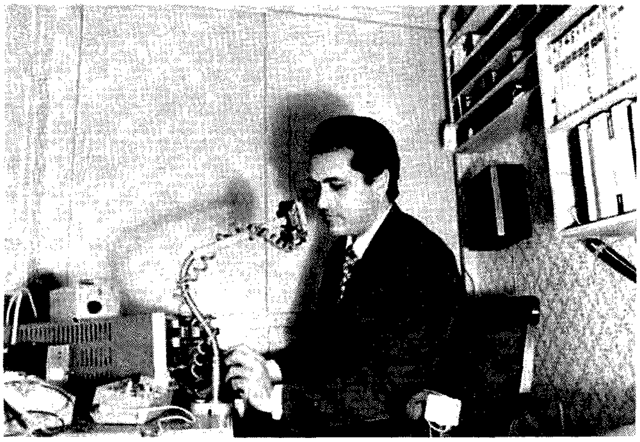
This week I was very happy to hear from my dear friend Professor Giulio Nardona, the President of the Radio Club Ciechi d'Italia. Giulio and his fellow amateurs are particularly proud of the following two awards.

The Radio Club of Blind Radio Amateurs of Italy has organized a new award entitled the RCCI DX Award. Starting from December 25, 1975, this award is open to all radio amateurs who can accumulate a total of 350 points as prescribed by the rules of the award.

Increments of 400, 500, and 600 points are earned with the delivery of blue, silver, and gold cockades to be fixed to the basic RCCI Award. In addition, every year prizes will be given to the first three amateurs better classified according to the points totaled during that year. Applicants scoring 600 points in the maximum of 10 years will be listed in the Honor Roll and will become Honorary Members of RCCI and will become "Jolly Stations" for this award.

To determine points, each country listed on the DXCC list of 1975 will have a value of one (1) point if worked on 15 and/or 20 meters. For contacts on 10, 40, or 80 meters, two points may be credited. A country may be worked only once on a band and contact with a Jolly Station may earn you 15 points; however, a Jolly Station may only be worked once.

Do not send QSL cards! Prepare a list of contacts, including date and time worked in GMT, band and mode of operation, and the points claimed for each contact. Have this list verified by at least two amateurs.



I0LL, the chairman of RCCI (Italian Radio Club for Blind Operators), in his shack. He is showing some of the instruments specifically manufactured by RCCI for blind amateurs.

Forward your application and an award fee of $4.00 or 10 IRCs to: RCCI Awards, I8KUT, PO Box 2011, 80100 Napoli, Italy, Europe.

The following stations earn the applicant 15 points: I0LL, I0PNK, I0SUQ, I0WFI, I0WHY, I1KJ, I3ANE, I4LDY, I8DOE, I8FTV, I8KUT, I8NMM, I8SRP, I8YRK, I0OGT, IT9VQC, and GM4ELV.

WORKED ITALIAN PREFIX AWARD

In remembrance of Pietro Spriano I0KA, founder and first President of the Radio Club of Blind Radio Amateurs of Italy, the organization has organized the Worked All Italian Prefix Award which becomes available to amateurs worldwide.

To qualify, all contacts must have been made on or after June 5, 1977. Contacts must be made with the following Italian prefixes: I1 through I0, IS0, IT9, one of the special ARI stations (IZ0ARI or I3ARI as examples), or one of the special memorial stations such as II4FGM or IY4FGM.

As with the RCCI Award, do not send QSL cards. GCR apply. Forward your application and an award fee of $4.00 or 10 IRCs to: I8KUT, PO Box 2011, 80100 Napoli, Italy, Europe.

Congratulations to Vernon G. Dameron, Jr. K1DRN of Bedford MA. He was the winner of a lifetime subscription to *73 Magazine* at the New England Division Convention, October 4 and 5, at Boxboro MA.

HAM HELP

I would like to obtain the service or instruction manual for a Wavetek VCG (generator), model 155. I will gladly pay a reasonable amount for a copy or the manual itself.

Arthur Hagopian W6LGQ
34 Laurel Ave.
Petaluma CA 94952

I need a copy of assembly instructions for a Hy-Gain tri-band beam, circa 1960. Commonly called the eggbeater because of the 23" loops on each end of the three elements, it has four open coils on each element and an 18' boom. I will pay for a copy.

Leslie Hogg WB8NVJ
28423 Kendallwood Dr.
Farmington Hills MI 48018

I am in need of operating manuals and schematics for the following test equipment: H-P model 520 high-speed decade scaler and model 500BR frequency meter and Sweep-Systems, Inc., model 950 oscilloscope. I will buy or reproduce and return and pay shipping costs. Thank you.

Stan Boler WD9BBV
116 S. Washington
Knightstown IN 46148

I need a manual for an AN/USM 106 video voltmeter made by Ballantine. I will pay postage and copying costs and prefer to copy here and return.

John Weber K4JW
102 Southgate Blvd.
Melbourne FL 32901

SOCIAL EVENTS

Listings in this column are provided free of charge on a space-available basis. The following information should be included in every announcement: sponsor, event, date, time, place, city, state, admission charge (if any), features, talk-in frequencies, and the name of whom to contact for further information. Announcements must be received two months prior to the month in which the event takes place. They should be sent directly to Editorial Offices, 73 Magazine, Pine Street, Peterborough NH 03458, Attn: Social Events.

SOUTH BEND IN
JAN 4

Talk-in on 146.34/.94 and 146.28/.88. For further information, contact the Richmond Amateur Telecommunications Society, PO Box 1070, Richmond VA 23208.

ARLINGTON HEIGHTS IL
JAN 25

The Wheaton Community Radio Amateurs' hamfest will be held on January 25, 1981, at the Arlington Park Race Track EXOP Center, Arlington Heights IL. Doors open at 8:00 am. Tickets are $2.00 in advance and $3.00 at the door. There will be 300 free flea market tables available, plus 100 commercial booths and clear paved parking. Prizes will be awarded. Talk-in on 146.94 and 146.01/.61. For advance tickets, send an SASE to WCRA, PO Box QSL, Wheaton IL 60187. For information, call (312)-766-1684 or (312)-629-3296.

MIAMI FL
FEB 7-8

The 21st *annual* Tropical Hamboree and 1981 ARRL Florida State Convention will be held on February 7-8, 1981, at the Flagler Dog Track, Miami FL. Registration is $3.00 in advance and $4.00 at the door. Swap tables are an additional $12.00 for both days, $7.00 for Saturday only, and $6.00 for Sunday only. Events will include tech talks and forums, over 100 exhibit booths, 400 swap tables, ladies' programs, group meetings, and many awards. There will be free overnight RV parking for self-contained units at the site (advance registration is recommended). Special gatherings are planned for QCWA/OOTC/SOWP and DXers. For further information and special hotel rates, write Dade Radio Club, PO Box 350045 Riverside Station, Miami FL 33135.

MANSFIELD OH
FEB 15

The Mansfield midwinter hamfest auction will be held on February 15, 1981, at the Richland County Fairgrounds, Mansfield OH. Doors will open to the public at 8:00 am. Tickets are $1.50 in advance and $2.00 at the door. Features will include prizes, an auction, and a flea market, all in a large heated building. Talk-in on 146.34/.94. For additional information, advance tickets, and/or tables, send an SASE to Harry Frietchen K8HF, 120 Homewood Road, Mansfield OH 44906, or phone (419)-529-2801.

LIVONIA MI
FEB 22

The Livonia Amateur Radio Club will hold its 11th annual LARC Swap 'n Shop on Sunday, February 22, 1981, from 8:00 am to 4:00 pm, at Churchill High School, Livonia MI. There will be plenty of tables available. Other features include door prizes, refreshments, and free parking. Talk-in on 146.52. For further information, send an SASBE (4" × 9") to Neil Coffin WA8GWL, c/o Livonia Amateur Radio Club, PO Box 2111, Livonia MI 48150.

DAVENPORT IA
MAR 1

The Davenport Radio Amateur Club will hold its tenth annual hamfest on March 1, 1981, from 8:00 am to 4:00 pm at the Davenport Masonic Temple, Highway 61 (Brady Street) and 7th Street, Davenport IA. Tickets are $2.00 in advance, $3.00 at the door. Tables are $4.00 each with a $2.00 additional charge for an electrical hookup (limited number). Features will include over $2,000 worth of major prizes. Hotel discounts and refreshments will be available. There will be a pre-hamfest Saturday night banquet with Paul Graver, midwest ARRL SCM, as guest speaker. Banquet tickets are $8.00 and reservations must be paid by February 18, 1981. Talk-in on 146.28/.88, WØBXR. For advance tickets, dinner, and table reservations, write Dave Johannsen WBØFBP, 2131 Myrtle, Davenport IA 52804.

STERLING IL
MAR 8

The Sterling-Rock Falls Amateur Radio Society will hold its 21st annual hamfest on Sunday, March 8, 1981, at the Sterling High School field house, 1608 4th Avenue, Sterling IL. Advance tickets are $2.00 and tickets at the door are $2.50. A large indoor flea market will be restricted to radio and electronic items only. Tables are available for $5.00 for commercial and $3.00 for others. Plenty of free parking will be available, including an area to accommodate campers and mobile trailers. Many prizes will be given away, including a first prize of a minicomputer. Doors open at 7:30 am. Featured will be a movie, "The World of Amateur Radio," to be shown throughout the day, bargains, good food, and plenty of close-by activities for XYLs and kids. Talk-in on .52 and WR9AER .25/.85. For advance tickets and tables, write Sue Peters KA9GNR, 511 8th Avenue, Sterling IL 61081. Make checks payable to Sterling-Rock Falls Amateur Radio Society and enclose an SASE.

CORRECTIONS

In "Single-Tone Paging for Wilson HTs," December, 1980, pp. 112-114, several errors managed to creep in, not the least of which was the author's old callsign. Fred's call *is* W4CK.

On page 112, zener D2 in Fig. 1 should be a 1N751A. This change should be reflected in the parts list on page 114, too. Also, on page 113, column 1, at the beginning of the bottom paragraph, the opening line should read "There is no *dis*advantage in..."

An improvement over the insulation technique described on page 114, column 2, lines 19 through 25, would be to use nonconducting styrofoam cut to the shape of the PCB.

Finally, at the bottom of the parts list, time and inflation have had their effect. Microsizer Co. (at the same address) now offers the kit for $17.95 and the PCB alone for $4.50.

HAM HELP

I am in need of a Galaxy III schematic and owner's manual. I will pay for original or copy. Thank you.

Phillip R. Lofton WA4NVE
349 Quinn Rd.
Collierville TN 38017

I am in need of the manual(s) for two Gonset, Inc., FM 150-175-MHz radios. One is a model 960A, series (G40033), while the other lacks a model number but is stamped with the series (G40019). The two are identical but for power supplies and number of channels.

I would, of course, be willing to pay for any costs involved in obtaining the paperwork for these radios.

Zak Hargraves, KA0EGW
550 East 30th Street
Durango CO 81301

I came across a few schematics the other day and started to destroy them and then I thought that someone might want them.

I have schematics available for the following: HT-33-B linear amplifier, Globe DSB-100 Sidebander, Heathkit® V-2 VTVM, typical Command Set transmitter, with power-plug connections for "BC" series, modification of Heath HP-10 for use with Collins KWM series, and the popular Command Receiver.

These are free for the asking—an SASE would be appreciated, however.

Reid Martin W4BP
Rt. #3 Box 250
Tavares FL 32778

I need very badly a noise blanker for a Drake TR-4C. The unit Drake made for this rig was numbered 34-PNB. I would like to buy an original unit or obtain photocopies of printed information pertaining to it (schematics, photos, etc.). I will pay a reasonable price for either or both, and, of course, all shipping costs.

If you have a 34-PNB that you are willing to sell, or have information (or know where I can get either), please drop me a note at the address given below. Please state condition of unit, nature of information, and a price (please exclude shipping costs from this figure). Your time and attention is greatly appreciated.

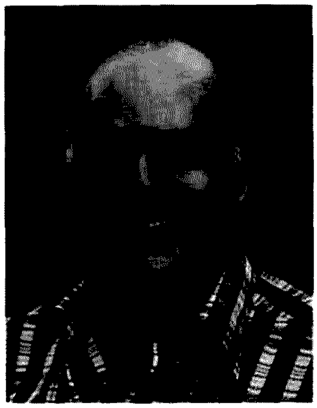
editorial by Wayne Green



HARC BOMB

That's the Hudson Division ARRL Convention...an almost complete disaster according to the few survivors. Hardly any exhibitors and one of the most scant attendances of any HARC Convention. Lest I be given a hard time for just reporting the debacle without making some suggestions for the improvement of the show, I'd like to suggest that the event be put in the hands of someone competent ...that a decent program be devised which features someone who will attract attendance ...that manufacturers and dealers be provided with low-cost exhibit facilities...that the event be advertised in more than just one ham magazine...and be run near New York City.

A ham convention is a show which has costs running into the tens or even hundreds of thousands of dollars. In the hands of someone with no experience in promoting a show and with no ease in handling large sums of money, it is going to be screwed up. A show promoter has to know how to organize local clubs to get the work done...he has to be experienced in wheeling and dealing with hotels and exhibition centers...with caterers...with entertainment. He has to already know about advertising, PR, mailing lists, direct-mail work, mail order... etc. In other words, you do not turn a big business over to someone who has spent a lifetime working for the telephone company.

HARC has over 40,000 hams in the area, so they should be able to put on the biggest hamfest or convention in the country. They should be able to make even Dayton look sick. With that kind of an attendance prospect a convention that draws under 1,000 is ridiculous.

How about turning to a show promoter...a professional? Well, maybe, but I've seen these birds work and they can screw you all ways to Sunday. They know all about skimming the gate, running up fake expenses, double billing...etc. I've seen some shows where it was obvious that $50,000 or more was being skimmed off the top.

Hamfests and conventions can draw well if they are run right and well advertised. Our hobby is in desperate need of more successful hamfests, for these events help bring out prospective hams and build up their enthusiasm. They can also make a lot of money for those who do the work.

KENWOOD

Visitors to Japan often arrive with a distorted idea of how terribly expensive the visit is going to be. Hotels *are* on the high side, but certainly are no worse than in London and much of Europe. A visit to Tokyo *can* be an expensive experience if one is not wily unto the ways of the natives. I found it much like New York City, where meals come in all price ranges.

A busy production line at Kenwood in Tokyo.

Not being able to completely overcome my frugal Yankee heritage, I tend to oscillate between a sort of fatalistic acceptance of the need to both give and enjoy lavish business entertainment and a lifetime of being thrifty. Thus, one evening I may be the guest (or even the host... aargh) of a fellow businessman and the next cadging free snacks in the food section of a Tokyo department store, armed with my best "I *may* buy some of this if I like it" smile.

The practice of almost all restaurants of having the food on display (plaster replicas, actually) in the front window, along with the price, makes it easy for the chintzy to shop for a cheap, but delicious meal. You can do nicely for $6 or $7, leaving the $200 dinners for more important evenings. If you get desperate, there are a number of American fast-food chains waiting for you. McDonalds is just about everywhere in Japan, ready when your Big Mac attack comes... and it eventually comes to everyone visiting a truly foreign country.

If a Big Mac doesn't get you, then you'll be able to get a reasonable and familiar meal at a Kentucky Fried Chicken, a Dairy Queen, or a Shakey's ("All the pizz and flies you can eat"). There's even a Wendy's...right there on the Ginza (Broadway) in Tokyo, complete with a standard Frosty. I'm a very big fan of the Wendy's salad bar, but that has not yet been exported... and I've checked 'em out in Brussels, too.

This trip to Tokyo had three major purposes. That was enough to keep me busy day and night, rushing to a computer show to see what the latest in Japanese microcomputers might be like...then talking with prospective trading partners about Instant Software... and meeting hams and ham equipment people. With quite a number of the Japanese firms promising to start exporting microcomputers to the US in 1981, I wanted to see what they had to offer and get an idea of what the

American firms are really up against. I found out and the news is not good for the American firms.

Since the US is quite a bit ahead of Japan in the development of programs for microcomputers, I was interested in developing a market in Japan for the nearly 1,000 programs which my firm, Instant Software, has either released or has ready for release. I needed a good sized firm which could translate our programs and distribute them in Japan. Despite the shortness of my visit to Tokyo, both of these objectives seem to have been accomplished. Time will tell.

The way for a visit with the people at Kenwood was paved by Ken Bourne W6HX, their US marketing manager. Everything went off in style, from being picked up at the hotel and driven to the factory to my talks with their engineers and a look at their production and research departments.

In the last few months I've written a good deal about some ideas I have for advancing ham equipment. I was hoping Kenwood might be interested in some of these ideas and perhaps put them through their research lab and end up with some practical equipment for us. Some of these ideas were first discussed at the 1980 Ham Industry Conference in Aspen and others have evolved since then. I find that I brainstorm the best with a group of ham engineers so I was really looking forward to the session.

All of the top people at Trio-Kenwood whom I met were accomplished in English, so our talks were not slowed down by the need for translations. The meeting started off with a presentation to me by Mr. Toshio Okuhara, the managing director, of a complete TR-2400 system. This a wonderful Japanese custom and one which I'm going to try to import.

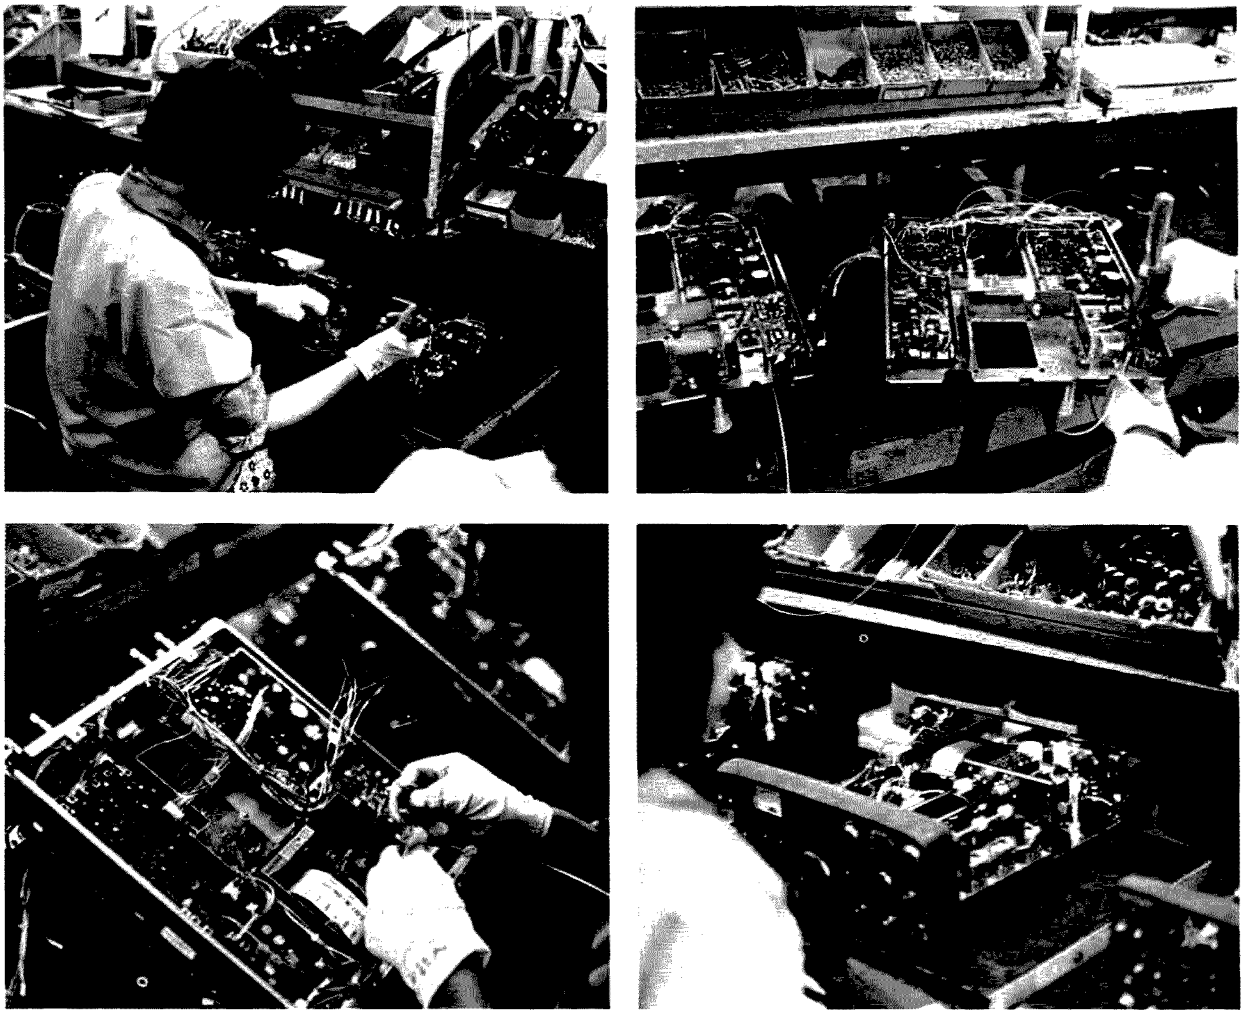
The Kenwood factory, while obviously efficient and well organized, was not remarkably different from some American firms I've visited. The quantities of units made is not large enough for the use of really automated systems such as I saw in Korea, where they were turning out color television sets with hardly any manual labor at all. No, the big difference between Kenwood and the American firms I've visited lies in their research laboratory. This was big, busy, and packed with avid hams.

The idea for a subaudible tone for automatic identification of ham rigs, which I have discussed in my editorials, certainly intrigued them. I think this one development alone could bring about major changes (for the better) in amateur radio. Obviously it would spark a whole new generation of transceivers . . . plus a lot of adapters for older rigs. This is just one more

Well . . . I Can Dream, Can't I?

by Bandel Linn K4PP

"And under the terms of the will, your uncle is leaving you $750,000—of which $50,000 must be spent for ham gear."



The empty chassis starts at one end and comes out with everything ready for testing.

A custom which is curious to Japan is one of presenting a gift to a visitor. While I'm usually good for a free lunch, here you can see Mr. Okuhara, the managing director of Kenwood, presenting me with a complete TR-2400 hand transceiver system . . . in return for a measly magazine.

marriage of digital electronics and amateur radio.

We also discussed some of the recent developments in narrowband single sideband which are promising us 5-kHz-wide repeaters for our VHF bands. Of course, if we are unable to get amateur radio back into a growth mode, we really won't need room for a whole lot more repeaters. I'm hoping that something can be done to get our growth back up over 10% so that eventually we'll be hurting for more repeater channels.

This meeting occurred before I'd bought one of the new Sony TC-300S stereo cassette recorders, so I hadn't yet come up with the idea for stereo double sideband. I did discuss DSB and its promise for providing up to 25 to 30 times more possible occupancy on our HF bands. I sure wish someone would start some work along that line. Will stereo be even better? We'll see.

Our talking ran on into dinnertime, so they took Sherry and me to Tokyo's famous garden restaurant, Chinzan-So, a place for entertaining honored guests (I got that from the brochure I picked up at the restaurant). The food, the service, and the location were spectacular.

Sometimes I get a bit depressed over not having the time and the facilities which I wish I had. I'd love to get into a lab for a few weeks and come up with a working piece of hardware for automatic identification. During these moments I suffer from flights of fancy about starting a lab and peopling it with ham experimenters. Then practicality sets in and I recognize that even if I was able to find people like that, there would be no way I could afford them. No, that sort of lab will have to be run by our manufacturers . . . for now.

You've heard about the high food prices in Tokyo? This is the menu at a food stand concession at the Consumer Electronic Show. Two hundred Yen is equal to $1 US, so you can see that the prices are not at all out of line with what you would pay at a concession stand in America. Soup needle, by the way, is noodle soup.

Here's Sherry working on the bowl of tempura soup needle ($1.75), which did a fair job of feeding both of us. In addition to the bowl of noodles and soup, there were a couple good-sized shrimp tempura.

Wendy's is not much different from anywhere else, with a double hamburger weighing in at around $3.15 with all the trimmings. One unusual item was a shrimp sandwich at $1.10.

I'll let you in on a secret. . . Wayne really likes the Wendy's Frosty.

A recent television show discussed the Japanese approach to driving: They make a big deal out of driving school. Here is a practice driving course laid out on the top of a garage. It is busy all day long. Does this extra training pay off? You bet! Per capita, the Japanese have less than 3% as many accidents as we do. You rarely see a car with dents or signs of body work. It is almost enough to make a politician think. . . but not quite.

For about $6 you get a lacquer tray full of food. Delicious, and identical to the beautifully made plaster model in the restaurant window. All I had to do was take the waiter out and point and we got our meals.

LOOKING WEST

Bill Pasternak WA6ITF
c/o The Westlink Radio Network
Suite 718
7046 Hollywood Blvd.
Hollywood CA 90028

They're at it again. The spectrum thieves, I mean. Those who view the 220-to-225-MHz band with an acquisitive eye, envisioning huge corporate profits if they can find a way to steal the band from those of us who now occupy it. Maybe 220 CB is dead, and maybe "the ARRL slew it" as it is claimed. Anyway, the ARRL has not been all that successful in convincing other potential spectrum thieves that they mean business. Nor do I think they can. No, guys and gals, I don't think we can count on Newington to pull us out of this one. We are going to have to conquer this one on our own. It means pulling together and taking the offensive once and for all. You and I are going to have to fight hard to save 220. Don't look for help anywhere else.

It seems that the latest attack is coming from Inland Waterways again. That's the same group we thought we had trounced last year. I guess some people never learn, because they are again eyeing 220 to 225 MHz to relieve the purported congestion in the 160-MHz marine band. Last year they wanted to construct an "Inland Waterways Automated Data Relay" system along the Mississippi and connecting waterways. Now they want more room for boats to talk, and pass the time of day. What next?

Well, there is a "next." It seems that the manufacturers of cordless telephones are also eyeing 220. Cordless phones are becoming very popular these days, and the people who make them are running out of room on 72 MHz. So they are reported to be looking at new spectrum in both the 27-MHz CB band and the 220-MHz amateur band for their exclusive use. The December, 1980, issue of *Popular Electronics* carried a rather interesting article on the subject. If you are a 220-MHz user, I suggest you read it and respond to the editors. Maybe they can help get the word back to industry that there are several thousand of us who are not willing to just go away. You can kind of discount the 27-MHz idea as there is no way for the cordless phones to be compatible with current CB activity, either within 27 MHz or on either side. So in reality I think we can assume that it's 220 they will go after. We have a two-pronged attack on us it seems, and it might wind up to be one heck of a fight. Why? Because both of these entities seem to believe that 220 to 225 MHz is vacant spectrum, that it is not in use by anyone, and is, therefore, ripe for the taking.

There are many ways in which we can fight the problem. In the past we have always taken the nice-guy approach, and year after year we face the same threat. Maybe it's time to forget that we are usually ladies and gentlemen and take a hard line: that 220 to 225 MHz is amateur, and that it will always remain amateur. Sounds like a challenge to war, you say? I prefer to think of it as a response to a challenge. A response which will educate spectrum thieves with respect to the abundant amateur activity on 220 and the fact that this activity is there to stay. That we as amateurs learned our lesson well when the FCC took 11 meters and created the CB fiasco. That we will never permit this to happen again. That the band is ours, that all of our bands are ours, and that we are prepared to fight to retain every last kilohertz.

Frankly, most of the VHF/UHF experts I have spoken with agree that it would be impossible to share the 220 band with any other service, be it Inland Waterways, cordless telephones, or what have you. The way we have structured the band in its development over the past 5 or 6 years precludes this. It might be possible if we did not have repeaters sitting atop mountains with the ability to talk over several hundred miles. Even in areas where repeaters talk over only 50 or 60 miles, the mutual interference would be massive and intolerable. In the end you would have another 27-MHz fiasco and no way to solve the problem. One or the other would have to go, and I know that the amateur community would stand pat and not budge. This could and would lead to an ongoing confrontation between the business community and the amateur. It would be a war that neither side could win, so why have it in the first place?

There is no way that FCC regulation could help make this spectrum sharing work. Look at the record, look at the present mess, called 27-MHz, Class D CB. Here you are dealing with technologically-incompetent people, for the most part. Appliance operators who buy a legal radio, an illegal amplifier, and talk worldwide. Has the Commission been able to solve the regulatory enforcement problem? Has the linear amplifier ban worked? Has *any* regulation or attempted enforcement of the 27-MHz problem worked? The answer is a resounding no! The FCC says it lacks the funds to do an effective job of enforcement on 11 meters, but even if they had the monies, I doubt if they could catch any but the most hard-core offenders. And, of those already caught, how many turn out to be repeat violators who care little or nothing about the rules to begin with?

Until now, industry and others have viewed the radio amateur as the tinkerer who is given the cast-off frequencies until such time as they are needed by someone else. It is thought that once a need arises, we amateurs will simply vanish as mysteriously as we came. This is a stereotype upon which we are viewed and judged. In part, the stereotype is justified because we have projected this image for so many years that it has become the thinking of today's society. What many fail to recognize is that another type of amateur has emerged in recent times. He may or may not be a technical whiz kid, but no longer is he a back-room boy; he has social awareness. He is the kind of guy who will not be trampled on by others. In some cases, this may have manifested itself in contemptuous behavior—jamming, foul language, or what have you. But the majority are well-respected professionals. Doctors, lawyers, broadcasters. You name it. People with an ear to the ground and an eye on society. Activists with strong beliefs and ideals. Slowly but surely these people became dedicated to the preservation of the amateur service and to its continued vitality.

The spectrum thieves seem unaware that this has happened. They are used to dealing with the Newington types that they usually can walk all over. What they have yet to catch onto is that in the battle over 220 they will not be dealing with Newington but rather with the people now on the band. People who long ago turned a deaf ear to the ARRL and have fought and won wars for themselves. Most of the 220 people in my part of the nation turn to Newington the same deaf ear they turn to VHF. So, "Mr. Businessman," in this one you must face the angry mob alone. For the first time in its long history, the amateur service is ready to break out of its traditional good-guy role to do battle with what they consider to be the enemy. You, "Mr. Cordless Telephone" and you, "Mr. Inland Waterways," you're far from being our "good buddy." We know what you spectrum thieves want, and believe me when I tell you to look elsewhere... like 800 or 900 MHz. We don't want you on 220 or near 220. From us to you: Go play in the bathtub with a toy boat.

You can't say you weren't warned.

A BOOK REVIEW

Well, he's done it again. One never knows what to expect next out of Bob Heil K9EID. Just when the effects of his previous amateur-radio-related escapade seem to begin fading, Bob goes ahead and pulls another rabbit out of his bottomless hat and hits home once again. Bob's latest creation is a book titled *The 10-Meter FM Handbook*. I've got a better title: "Everything and Anything You Ever Wanted to Know About 10-Meter FM When You Didn't Know Whom to Ask the Questions Of." It's that inclusive.

For those of you who may not be familiar with Bob, he is the founder and president of Heil Sound Ltd., an electronics manufacturer of professional audio equipment for the entertainment industry. Since 1956, he has been one of the pioneers of VHF, SSB, and he spends a

RTTY LOOP

Marc I. Leavey, M.D. WA3AJR
4006 Winlee Road
Randallstown MD 21133

In all the years that I have been writing this column, I have always tried to keep the tone light and cheerful. It is with some regret, therefore, that I must alter the tone this month, as I begin with an obituary.

Although not involved with amateur radioteletype at its inception, being only twenty-eight years old, this youngster played an important role in the introduction of new features in RTTY operation, such as selective calling, that we still appreciate today. Most of us became acquainted with this relative newcomer after getting involved in RTTY, and many remain attached, even to this day.

Several siblings have been quite influential in the growing computer field and, in a wanton act of genocide, they also are being dispatched. Yes, we'll miss them. But have no fear, for in the surplus market they shall live on to be resurrected time and time again as this part and that is replaced, much as those long gone have done before.

What am I talking about? Why, the Model 28 Teletype®, of course! The Teletype Corporation will cease production of this venerable machine soon. Others in the line, most notably the ASCII Model 33, also will go out of production. While spare parts will be maintained, and most of us did not get ours new anyway, it feels like another era is passing by.

If one era passes, though, then another arrives—and that's just what I am going to write about this month. One of the most exciting new developments in ham RTTY is the introduction of the computerized RTTY terminal. It is hard to pick up a magazine and miss the ads for the many complicated boxes which seem to do everything but turn off the shack lights when you are done operating. And now, RTTY Loop will take a close look at one of them: the Microlog ATR-6800.

About three years ago, the Microlog Corporation, located here in Maryland, introduced a video RTTY system. Based on the Motorola 6800 microprocessor, the system featured separate transmit (AKB-1) and receive (AVR-1) units, a video monitor, and a raft of options. Buying one fully stocked would have cost you about twelve hundred 1978 dollars. As experience has been gained, new features have been devised and the company's latest offering, the ATR-6800, packs it all into one box only slightly larger than the keyboard of three years ago. For a shade under two thousand 1981 dollars, it runs rings around the old system. Unfortunately, some compromises had to be made to fit everything in there, and I will cover some of them after going over the highlights of the unit.

First off, what can it do? Well, the basics of the unit include a 6800 microprocessor supported by a monitor program in 2716 PROM, about 4K of RAM, and one and one-half PIAs. Into all of this is stuffed enough programming to satisfy almost any operator. Data exchange is by any of three modes: Morse code, Baudot code, or ASCII. Transmission rates are available for any common, and a few not so common, speeds. From the user's point of view, operation is remarkably constant no matter what the code, so let's look at that first.

The video display is a black and white 24-line-by-40-character display. At the top of the display, a dedicated line shows the current transmit/receive status, mode, speed, and time. The time is maintained in an internal twenty-four hour clock set from the keyboard. The display is selectable as white on black or black on white, and a zoom command produces a twelve-line-by-twenty-character display that can be read from across the room—even on the small Sanyo, nine-inch monitor. The display is normally maintained in a split-screen format with the transmit buffer on top and the received data below a dashed line. The transmit buffer display may be removed entirely or its size varied from one to twenty lines (seven lines maximum in the zoom format).

There are several outputs available from the ATR-6800 that allow interfacing to a wide variety of devices. Standard video goes to the monitor, of course. A high-speed mercury relay is available to insert in a loop supply to allow hard copy on a teleprinter. Computer-compatible RS-232 levels also are provided so that devices using this transmission standard may be connected. For turning the transmitter on and off, voltage keying is available for both positive and negative circuits. AFSK tones also are generated, and their frequency and shift may be specified from the keyboard. Options are available to either silence the output tones during receive or leave them on, thus allowing VOX keying, if desired.

Inputs include speaker audio as well as TTL or dry contacts for a hand key or whatever. Again, RS-232 interfacing is provided for users of this standard. Now, not only can you connect the receiver, transmitter, and old clunker printer, but interfacing is provided also for a standard cassette recorder. Why? To save pictures, messages, or whatever, and send these plus your own "brag tape." Keyboard controlled, of course. To aid in tuning, outputs are provided also for an oscilloscope which will display a "cross" type of tuning pattern on received signals.

The operating system provides several features which may be used no matter what the mode. An ID key may be programmed to send the station's identification whenever pressed, and an alternate (SHIFT-ID) can send another one, perhaps including an automatic CW ID for RTTY operation. Ten messages may be stored and recalled actively during a QSO. A test signal may be sent appropriate to the mode in use: RYRYRY in Baudot, U*U*U*U* in ASCII, or VVV in Morse. We've all heard of diddle, that familiar sending of LETTERS when not sending anything else. Well, when you select this mode in Morse, the time is filled with BT (-. . . -) so that the other guy does not think you died.

Let's see, what else can I tell you? You can tell the thing to send each letter as you type it, to delay sending a word until you type a space, or to send the whole line after a carriage return only. Makes editing nice and easy, especially on Morse. (I can type faster than I can send Morse—much faster!)

What's that you say, "the modes"? Ah, yes, the modes. Well, you see, you have your Morse, your Baudot, and your ASCII. Now, when you are in Morse, the transmit speed may be adjusted in one-word-per-minute increments from five to 199 words per minute. The receive speed is self-tracking to the speed of the sending station. All of the special Morse signs, such as SK, AR, BT, KN, and varied and sundry punctuation marks are supported. And, of course, all of the general features mentioned above work just fine. When you are in Morse, the front end of the ATR-6800 functions as a direct detector, looking for an 800-Hz tone. When it finds that frequency, it locks on and the fun begins.

Now, in Baudot you have a choice of 45.45 baud (also known as the 60-word-per-minute standard) as well as 50, 57, 74, and 100 baud, corresponding to 66, 75, 100, and 132 words per minute. All kinds of RTTY niceties can be called into play here, such as downshift (or non-downshift) on space, automatic carriage return, line feed after so many characters, or remoting to an external printer. In this mode, the input is routed through a computer-enhanced demodulator, which detects the usual 2125 Hz-2975 Hz pair, with other tones selectable from the keyboard.

By selecting one of the standard ASCII transmission rates, 110 or 300 baud, the encoding is switched to ASCII with the full character set supported. Much as with many other primarily uppercase machines, you must shift to get lowercase, but this is a minor inconvenience as text editing is not one of the primary applications of the machine. Although the full ASCII appears to be generated, the display ROM does not have all of the appropriate symbols in it. It uses, rather, several patterns of dots for several of the codes. This causes no real problem unless you are fond of braces instead of parentheses, or tildes, or several other of the less-used symbols.

Besides communicating on the air, the ASCII capability can be directed through a "computer" mode in which the ATR-6800 becomes essentially a stupid

CONTESTS

Robert Baker WB2GFE
15 Windsor Dr.
Atco NJ 08004

CWSP INTERNATIONAL DX COMPETITION
0000 GMT February 7
2400 GMT February 8

Amateurs throughout the world are invited to participate in the annual CWSP contest using all bands on CW only. Entry classes include a) single operator, b) multi-operator (only club stations, single transmitter), and c) QRP limited to 10 Watts with a single operator.

EXCHANGE:

RST and QSO number starting with 001. CWSP members will add "/CWSP" after the report. QRP operators will add "/power." Example: 579015/5.

SCORING:

QSOs with same country = 1 point, other countries in same continent = 2 points, and other continents = 3 points each. Multipliers are ARRL DXCC countries and each Brazilian prefix (PY1, PT7, PS8, etc.). Multipliers are counted only once regardless of band. Final score is total QSO points times the total multiplier.

AWARDS:

Cup and award to 1st place worldwide. Medal and award to 1st place in each continent. Awards to 1st place in each country. Special awards to 1st and 2nd CWSP members. Other special awards for clubs and QRP 1st worldwide and 1st Brazil.

ENTRIES:

Logs must contain data and time in GMT, station worked, exchange, multipliers, and points per band. Please use separate logs for each band. Logs and summary sheet must be mailed not later than March 15, 1981, to: CWSP Contest Committee, PO Box 15098, 01000 Sao Paulo, SP —Brazil.

1980 RESULTS:

1st World = PY1ARS/4; 1st South America = PY8BI; 1st North America = WA4OML; 1st USA = W1OPJ.

NEW HAMPSHIRE QSO PARTY
2000 GMT February 7 to
0500 GMT February 8
1400 GMT February 8 to
0200 GMT February 9

Sponsored by the Concord Brasspounders, the contest is open to all radio amateurs. Each station may be contacted once per band, per mode.

EXCHANGE:

RS(T) and NH county/ARRL section or country.

FREQUENCIES:

CW—1810, 3555, 3730, 7055, 7130, 14055, 21055, 21130, 28130.

Phone—1820, 3935, 3975, 7235, 14280, 21380, 28575, 50.115, 145.015.

SCORING:

Score 5 points for each NH station contacted and multiply by the number of NH counties worked. NH stations score 1 point for each QSO and multiply by the total number of ARRL sections, countries, and NH counties.

ENTRIES:

Logs with summary sheet and dupe sheet should be mailed not later than March 16, 1981, to: O. W. H. Johnson, Box 63, Bristol NH 03222.

VERMONT QSO PARTY
2100 GMT February 7
0100 GMT February 9

Sponsored by the Central Vermont Amateur Radio Club, stations may be worked once per band and mode. VT mobile stations may be worked again considering each new county they enter as a new station.

EXCHANGE:

QSO number, RS(T), and VT county or ARRL section.

FREQUENCIES:

3685, 3909, 3932, 7060, 7265, 7290, 14060, 14290, 14345, 21060, 21375, 28100, 28600, 50.260, 50.360, 144-144.5, 145.8.

SCORING:

Score 3 points per contact and multiply by the number of VT counties worked on each band. VT stations score 1 point per QSO and multiply by the number of ARRL sections and countries worked.

AWARDS:

Certificates to highest scoring station in each ARRL sec-

tion and country. Trophy to highest scoring single-operator station in VT. Additionally, their names will be added to the Doris McGrath memorial plaque. Donated in memory of W1EOB, this award will be awarded in this manner for a 10-year period. The operator winning the QSO party the most times or the station with the highest score during the period will receive the plaque. Other certificates for 2nd, 3rd, and 4th highest scoring stations in VT. The W-VT (Worked Vermont) Award will be issued to stations working 13 out of Vermont's 14 counties, provided the station has not previously received this award. A special certificate will also be awarded VT multi-operator stations.

ENTRIES:

Send logs or facsimiles together with an SASE no later than March 31, 1981, to: Gerald W. Benedict, W1BD, 23 Foster Street, Montpelier VT 05602.

LAND O' LINCOLN QSO PARTY

0000 GMT February 9
2400 GMT February 10

The contest is sponsored by the Land o' Lincoln chapter of 10-X International in cooperation with the Central Illinois Radio Club. Operating throughout the 10-meter band on CW and phone, LOL and CIRC members will call "CQ LOL" in an effort to contact as many stations as possible.

EXCHANGE:

Name, QTH, RS(T), serial number, 10-X number if any, and LOL certificate number if any.

SCORING:

LOL certificate holders worldwide and CIRC members score 1 point per QSO, 2 points per QSO with 10-X number exchange, and 3 points per QSP with LOL number exchange. Multiply total QSO points (3 max per QSO) by number of different states, Canadian provinces, and DXCC countries worked.

All others, score 1 point per QSO with LOL certificate holders, 2 points per QSO with local LOL and CIRC members. Multiply total QSO points (2 max per QSO) by number of different states, Canadian provinces, and DXCC countries worked.

Achievement certificates will be awarded to the top scorers in each state, Canadian province, and DXCC country. A special Novice certificate will also be awarded. Make sure to denote Novice on your entry!

ENTRIES:

Logs, fully duped and summarized, to be submitted no later than March 15, 1981, to: AG9E, Dave Meiser, 1112 Andover, Bloomington IL 61701. Please include an SASE for special QSO and/or results.

QCWA QSO PARTY—CW

0001 GMT February 14
2400 GMT February 15

This is the 24th annual QCWA QSO party with separate weekends for CW and phone. Contacts with the same station on more than one band can be scored only once. Contacts made with "captive" stations, such as when operating in local nets, are not valid.

EXCHANGE:

QSO number, operator's name, and QCWA chapter identification (official number or name). Members not affiliated with a chapter should use "AL." If a member belongs to several chapters, then *one* must be chosen and used for the QSO Party. If desired, you may use one chapter for the CW Party and another one that you belong to for the Phone Party.

FREQUENCIES:

Any authorized amateur frequency is permissible. The following suggested frequencies have been selected to minimize interference to others:

Phone—3900-3930, 7230-7260, 14280-14310, 21350-21380, 28600-28630.

CW—3530-3560, 7030-7060, 14030-14060, 21040-21070, 28040-29070.

SCORING:

Each contact made with another QCWA member will count as a single point. Add up the contacts with QCWA members and then multiply this number by the number of Chapters represented.

AWARDS:

Plaques for the top phone and top CW scorers. Certificates will be given for the 2nd through 5th runners up in both the phone and CW Parties. Standings and scores will be published in the *QCWA NEWS* summer, 1981, issue.

ENTRIES:

Logs should include the following information: Time (GMT), call, QSO numbers, name, Chapter number or name, state or country. It is the responsibility of each contestant to provide a legible log (no carbon copies) and to list all claimed contacts. The total contacts for each page will be recorded at the bottom of each page. The total contacts for the Party should be recorded at the top-right of the first page of the log. Log sheets will not be returned. Make sure you have correct postage when you mail your logs. Send logs no later than March 31, 1981, to: Pelican Chapter QCWA, Arthur M. Monsees W4BK, 1407 48th Avenue NE, St. Petersburg FL 33703. Separate logs and scores must be submitted for both the CW and phone Parties. The decision of the Pelican Chapter of QCWA will be final with respect to scores and rules. In the event of errors or a disagreement, keep all details off the air and write either the Pelican Chapter or QCWA Headquarters.

ALGOA BRANCH MERIT AWARD

This past month some very encouraging letters of support have been received from all parts of the world. Of particular note was the letter I received from Fred Strutt ZS2JS, representing the Algoa Branch of the South African Radio League. In his letter, Fred tells of their new award recognizing operator efficiency in CW communications.

The Algoa Branch Merit Award will be issued to any radio amateur who has had a minimum of 250 CW QSOs with any other amateurs of the world.

To qualify, all contacts must have been made after January 1, 1979. While QSLs are not required, the applicant must have his list of contacts verified by at least two fellow amateurs or by a radio club secretary. Endorsements will be issued in increments of 250 CW QSOs.

To apply, forward your verified list of CW contacts and an award fee of five (5) IRCs to: Algoa Branch Merit Award, PO Box 10050, Linton Grange, Port Elizabeth 6015, South Africa.

It has been some time since we have listed an Asian continent award. Without further ado, allow me to share with you a letter I received from our dear friend, Mr. Green VS6EZ. In his letter, Anthony tells us of two awards being made available by amateur associates in his country, the Hong Kong Amateur Radio Transmitting Society (HARTS).

THE HONG KONG FIRECRACKER AWARD

Sponsored by HARTS, the Firecracker Award is issued to licensed amateurs and shortwave listeners worldwide. Contacts on or after January 1, 1964, are valid.

To qualify for their very spectacular diploma, applicants within zones 18, 19, 24, 25, 26, 27, and 28 require confirmation with at least 10 individual VS6 stations. All other zones of the world require only six (6) VS6 contacts to qualify for the award. Awards are issued for all CW, all phone, and mixed mode. Single-band accomplishments will be recognized if requested at the time of application.

Do not send QSL cards! Prepare a list of claimed contacts and have them verified by at least two amateurs or a radio club secretary. Forward this list and an award fee of 10 IRCs to: HARTS, Post Box 541, Hong Kong.

NINE DRAGONS AWARD

Probably one of the most elaborate of my Far Eastern awards is the achievement diploma known as the Nine Dragons Award. Sponsored by HARTS, this brilliant award with its red, black, and shiny gold accents an amateur's wall with the dignity that makes all award seekers proud.

To qualify, the applicant must make contact with a country in each of the following zones: 18, 19, 24, 25, 26, 27, 28, 29, and 30. The contact made in zone 24 must be with a VS6 station. Stations located within any of these nine zones will require two (2) contacts in each zone as above.

To be valid, all contacts must be made after January 1, 1979. There are no band or mode restrictions for this award; however, special recognition will be granted if requested at the time application is made.

To apply, prepare your list of claimed contacts and have it verified by at least two amateurs or a radio club secretary. Send this list and an award fee of $2.00 or 10 IRCs to: HARTS, Post Box 541, Hong Kong.

While in Asia, it would be proper to review one of the largest awards programs in that part of the world, the one sponsored by JARL, more commonly referred to as the Japan Amateur Radio League.

ADXA AWARD

Sponsored by JARL, the ADXA (Asian DX Award) is available to licensed amateurs and shortwave listening stations worldwide. To qualify, all claimed contacts must have been made on and after July 30, 1952.

The requirements for ADXA are fairly straightforward. Applicants must establish two-way contact with at least thirty (30) countries in the Asian continent. A list of eligible countries appears below.

Do not send QSL cards! Prepare a list of claimed contacts and have it verifed by at least two fellow amateurs or a local radio club official.

Forward your application and an award fee of 8 IRCs directly to: Awards Manager, JARL, Post Box 377, Tokyo Central, Tokyo, Japan.

ADXA Countries: A4, A51, A6, A7, A9, AP, BV, BF-BU, CR9, EP, EP, HM-HL, JA-JE-JJ, JR, JD1 (KG6I), JD1, JT, JY, OD5, S21, TA, UA9-UA0, UD6, UF6, UG6, UH8, UI8, UJ8, UL7, UM8, VS6, VU, VU2-VU7-VU9, VU5-VU7, XU, XV5 (3W8), XW8, XZ2, YA, YI, YK, 1S, 4S7, 4W, 4X4-4Z4, 5B4, 7O, 8Q6, 8Z4, 9K2, 9M2, 9N1, 9V1.

WORKED/HEARD ALL JAPAN PREFECTURES

Also sponsored by the Japan Amateur Radio League, the WAJA Award is available to licensed amateurs and SWL stations on a heard-only basis. All contacts, to be valid, must have been made on or after July 30, 1952. The only exception to that rule is for contacts with Okinawa (JR6), for which contacts on or after May 15, 1972, are considered valid for this award. In addition, all contacts must be made only with fixed base stations.

To qualify, the applicant must make contact with a Japanese amateur operator in each of the 47 Japanese prefectures as they appear below.

Do not send QSL cards! Have your list of claimed prefectures verified by at least two amateurs or a local radio club secretary. Send this list and an award fee of 8 IRCs to: JARL Awards Manager, Post Box 377, Tokyo Central, Tokyo, Japan.

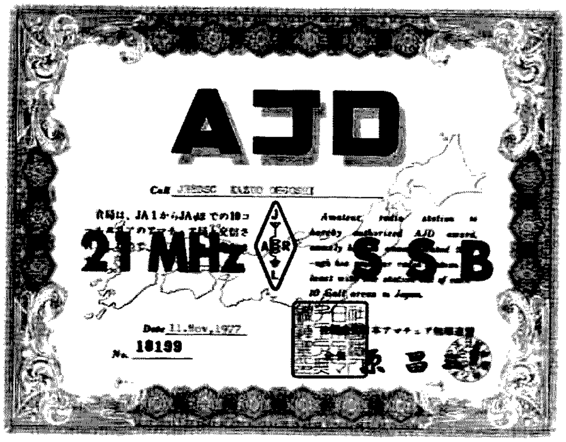
Japanese prefectures: JA1—Tokyo, Kanagawa, Chiba, Saitama, Ibaraki, Tochigl, Gumma, Yamanashi; JA2—Shizuoka, Gifu, Aichi, Mie; JA3—Kyoto, Shiga, Nara, Osaka, Wakayama, Hyogo; JA4—Okayama, Shimane, Yamaguchi, Tottori, Hiroshima; JA5—Kagawa, Tokushima, Ehime, Kochi; JA6—Fukuoka, Saga, Nagasaki, Kumamoto, Oita, Miyazaki, Kagoshima, Okinawa (JR6); JA7—Aomori, Iwate, Akita, Yamagata, Miyagi, Fukushima; JA8—Hokkaido; JA9—Toyama, Fukui, Ishikawa, and JA0—Niigata, Nagano.

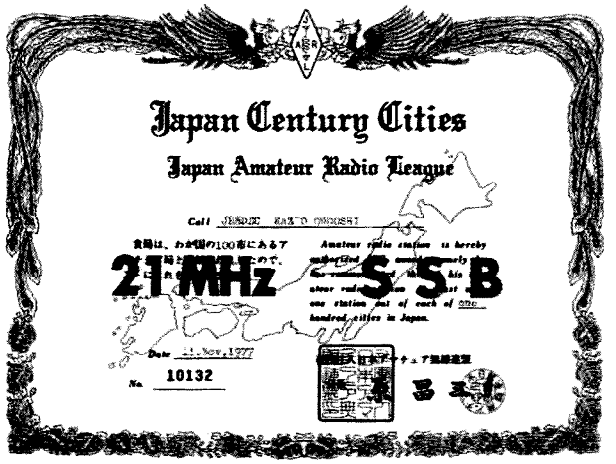
ALL JAPAN DISTRICTS AWARD

The Worked All Japan Districts Award is sponsored by the JARL and is available to licensed amateurs and SWL stations on a heard-only basis. This very basic award requires the applicant to make contact with one Japan station in each of the ten Japanese call districts.

This award is issued for single- and mixed-band accomplishments and also recognizes single- and mixed-mode achievements as well. To be valid, all contacts must have been made on or after July 30, 1952.

To apply, have your list of contacts verified by at least two amateurs or a local radio club official. Keep in mind that KA





stations (US military) will not be accepted for award credit.

Send your application with an award fee of eight (8) IRCs to the Awards Manager, JARL, Post Box 377, Tokyo Central, Tokyo, Japan.

JAPAN CENTURY CITIES AWARD

Similar to our own *73 Magazine* Century Cities Award, the Japanese version is sponsored by the JARL, requiring the applicant to make contact with a minimum of 100 individual cities within Japan. There are no further requirements and no stipulation as to band or mode. Endorsements are issued for each increment of 100 additional cities worked.

Applicants are asked not to send QSL cards! Prepare your list of cities in order of the city number. Though this may be confusing to some, it is best to write the JARL for a copy of this cities listing. This will enable you to make quick reference to the actual number assigned each city and will speed preparation of your application.

Once arranged in order, have your list of contacts verified by at least two fellow amateurs or a local radio club official. Send the application and an award fee of eight (8) IRCs to: JARL Awards Manager, Post Box 377, Tokyo Central, Tokyo, Japan.

As a final note, for those applicants who are fortunate enough to work all cities listed in Japan, a special Worked All Cities Award has been designed especially to recognize your feat!

Representing the Naniwa Club in Japan, Akio Sonoda JR3DDQ recently wrote me and asked that I share his club's new award with our many readers. With pleasure I present—

THE JAPAN OSAKA CENTURY CERTIFICATE

The JOCC Award is issued by the Naniwa Amateur Radio Club of Japan. It is made available to licensed amateurs throughout the world. To qualify for the award, applicants must submit proof of contact with stations within the Osaka prefecture. Three award categories are offered:

- Junior Class—applicant must work 10 JA stations which enable you to spell "NANIWA CLUB" with the last letter of each callsign contacted.
- Standard Class—applicant must work 10 different stations in the Osaka prefecture. Gold seal endorsements will be issued for each increment of 50.
- Special Class—applicants must work 100 different stations in the Osaka Prefecture, including 62 stations located in all 31 cities, 5 guns, and 26 wards of the prefecture. Note: A list of cities, guns, and wards is available from the Awards Manager for three (3) IRCs.

There are no band or mode requirements, but special recognition will be made if a request is made at the time of application.

Do not send QSL cards! Have your list of contacts verified by at least two amateurs or a radio club official. Send your application and eight (8) IRCs to the Awards Manger, Akio Sonoda JR3DDQ, 3-6-8 Daikoku-cho, Naniwa-chu, Osaka, Japan 556. For Gold Seal endorsements,

OPERATION BALLARAT

There are at least two Ballarats. One is a thriving city in southern Australia, about 240 kilometers north of Melbourne. It boasts a population of approximately 75,000 and is the principal city in Australia's gold country. It is a modern city with an air of progress and prosperity.

In extreme contrast is the other Ballarat. It is an almost forgotten ghost town in the rugged desolate mountain range which rings California's Death Valley. The California Ballarat is tied to Australia's through a young prospector named George Riggins, who, in 1897, came from the famous Australian mining center of Ballarat.

The prospectors who gathered in the Panamint mountain range wanted a town named where they struck it rich. Riggins suggested the new town be given the name identified with gold the world over and it was named Ballarat. However, in the early decade of the new century, the mines were exhausted and the town of Ballarat, California, became deserted.

Now, almost 100 years later, amateur radio will briefly revive the town. For a short period during the winter weekend of January 30-31 and February 1, 1981, the old ghost town will become alive again. This time it will not be humming mining machinery or tall head frames towering above the hills hauling gold ore from the mine shafts. It will be humming from the sound of gasoline-driven emergency generators.

Towering beam antennas and dipoles will replace the head frames and ore crushers. The miners' trademark, the pick and the shovel, will be replaced with radio operators' microphones and headsets. The prize will not be the gold nuggets but a certificate, showing today's scene from both Ballarats, linked together, although 10,000 kilometers apart.

To participate in this first-of-a-kind event, you must contact both Ballarats on either 10, 15, 20, or 40 meters on SSB. Some of you may also be interested to know that the California Ballarat is located in sparsely populated Inyo County and is probably high on many county hunters' most wanted lists.

By this time, you may be curious enough to wonder how all this is going to happen. Early, Friday, January 30, an advance group will leave the Los Angeles area, drive about 400 kilometers through the Mojave Desert into the Panamints and what is left of Ballarat. A suitable site will be selected and a VHF station will be established to guide those that follow later that day.

When the four HF transceivers, three 500-Watt linear amplifiers, beam antennas, the 1-kW gasoline-electric generators, and the balance of the support equipment have arrived, we will start to set up. By then, the group of twenty will be in work teams with each receiving its task. The criterion to demonstrate the establishment of an emergency communications center in a desolate area within a two-hour period is just a side objective of this weekend activity.

At 0200Z on Saturday, January 31, we will be ready to go to work. We will operate 28.100-28.600, 21.135-21.370, and 14.275-14.350 MHz until 1400Z, February 2, when the last contact from the ghost town will be acknowledged.

We will first look for our namesake in Australia, as it would be nice to have the first contact with them. But here is what is important for you if want to participate and obtain a certificate. You must communicate with *two* out of twenty stations in Ballarat, Australia, and the one at the ghost town. Give your callsign and signal report. You will get an identifier, a sequential number, and the last two characters of the Ballarat station's callsign. It will always be 6C from the ghost-town station and two letters from Australia. Contact the other Ballarat and give your callsign and the identifier you received. It does not matter which Ballarat you contact first. That way we can verify that you qualify for the certificate.

Send your name, callsign, identifier, address, and one IRC (International Reply Coupon) to WA6NKL, 4817 Paseo de Las Tortugas, Torrance CA 90505, or VK3VEZ, 2 Cambridge Street, Wendouree, Victoria 3355, Australia. Your certificate will be on its way shortly. Good luck.

Paul M. Turkheimer WA6NKL

OSCAR ORBITS

Courtesy of AMSAT

The OSCAR satellites are subject to atmospheric drag, of course, and the present period of intense solar activity has accentuated the problem. During this period, our sun has been expelling huge numbers of charged particles, some of which find their way into the Earth's upper atmosphere, increasing the density (and thus the drag) there. It is through this region that the OSCARs must pass. OSCAR 8, in a lower orbit than OSCAR 7, is the more seriously affected of the two.

If the drag factor is not considered when OSCAR calculations are performed, long-range orbital projections will be in error. For example, by the end of 1979, OSCAR 8 was more than 20 minutes ahead of some published schedules. The nature of orbital mechanics is such that extra drag on a satellite causes it to move into a lower orbit, resulting in a shorter orbital period. Thus, the satellite arrives above a given Earthbound location earlier than predicted.

Using data supplied to us by Dr. Thomas A. Clark W3IWI of AMSAT, the equatorial crossing tables shown here were generated with the aid of a TRS-80™ microcomputer. The tables take into account the effects of atmospheric drag and should be in error by a few seconds at most.

The listed data tells you the time and place that OSCAR 7 and OSCAR 8 cross the equator in an ascending orbit for the first time each day. To calculate successive OSCAR 7 orbits, make a list of the first orbit number and the next twelve orbits for that day. List the time of the first orbit. Each successive orbit is 115 minutes later (two hours less five minutes). The chart gives the longitude of the day's first ascending (northbound) equatorial crossing. Add 29° for each succeeding orbit. When OSCAR is ascending on the other side of the world from you, it will descend over you. To find the equatorial descending longitude, subtract 166° from the ascending longitude. To find the time OSCAR 7 passes the North Pole, add 29 minutes to the time it passes the equator. You should be able to hear OSCAR 7 when it is within 45 degrees of you. The easiest way to determine if OSCAR is above the horizon (and thus within range) at your location is to take a globe and draw a circle with a radius of 2450 miles (4000 kilometers) from your QTH. If OSCAR passes above that circle, you should be able to hear it. If it passes right overhead, you should hear it for about 24 minutes total. OSCAR 7 will pass an imaginary line drawn from San Francisco to Norfolk about 12 minutes after passing the equator. Add about a minute for each 200 miles that you live north of this line. If OSCAR passes 15° east or west of you, add another minute; at 30°, three minutes; at 45°, ten minutes. Mode A: 145.85-.95 MHz uplink, 29.4-29.5 MHz downlink, beacon at 29.502 MHz. Mode B: 432.125-.175 MHz uplink, 145.975-.925 MHz downlink, beacon at 145.972 MHz.

At press time, OSCAR 7 was scheduled to be in Mode A on odd numbered days of the year and in Mode B on even numbered days. Monday is QRP day on OSCAR 7, while Wednesdays are set aside for experiments and are not available for use.

OSCAR 8 calculations are similar to those for OSCAR 7, with some important exceptions. Instead of making 13 orbits each day, OSCAR 8 makes 14 orbits during each 24-hour period. The orbital period of OSCAR 8 is therefore somewhat shorter: 103 minutes.

To calculate successive OSCAR 8 orbits, make a list of the first orbit number (from the OSCAR 8 chart) and the next thirteen orbits for that day. List the time of the first orbit. Each successive orbit is then 103 minutes later. The chart gives the longitude of the day's first ascending equatorial crossing. Add 26° for each succeeding orbit. To find the time OSCAR 8 passes the North Pole, add 26 minutes to the time it crosses the equator. OSCAR 8 will cross the imaginary San Francisco-to-Norfolk line about 11 minutes after crossing the equator. Mode A: 145.85-.95 MHz uplink, 29.4-29.50 MHz downlink, beacon at 29.40 MHz. Mode J: 145.90-146.00 MHz uplink, 435.20-435.10 MHz downlink, beacon on 435.090 MHz.

OSCAR 8 is in Mode A on Mondays and Thursdays, Mode J on Saturdays and Sundays, and both modes simultaneously on Tuesdays and Fridays. As with OSCAR 7, Wednesdays are reserved for experiments.

FUN!

John Edwards WB2IBE
78-56 86th Street
Glendale NY 11385

DXing! Some call it a passion, others call it an addiction; many call it nothing at all and blithely work W8s and KA6s. Whatever your personal opinion, it's evident that DXing is a primary motivating force behind all of amateur radio. After all, even if you don't work DX, chances are it still directly affects your day-to-day hamming. (Ever try to work a friend in another state on 14.210?)

When did DXing start? Probably the first time a ham attempted to work a station over a distance greater than to his neighbor. Legend has it that the first pile-up occurred the following day. Want to learn more? Read on.

ELEMENT 1—CROSSWORD PUZZLE (Illustration 1)

Across

1 Famous DXpedition island
8 Lebanese prefix
9 Prefix of 1 across
10 Japanese rig: rice______
12 Father Moran's country
14 Over
15 Greenland—MARS prefix
16 Region 1 continent (abbr.)
19 International radio regulators (abbr.)
20 Ten, at night, on cycle's bottom
21 Greek prefix
23 DXer's reaction to hearing a new country
26 Home QTH for many
28 OSCAR group (abbr.)
30 Morse question mark
31 Egyptian prefix
33 Italian prefix
34 Time when you want QSLs
37 Foreign QSL clearinghouse (2 words)
41 WARC site
43 Four-land state (abbr.)
44 Good night (abbr.)
47 DX operating technique (2 words)

Down

1 Competitive pastime
2 Mystery signal (abbr.)
3 DX operating trap
4 Rig's output (abbr.)
5 5V-land
6 Noise blanker (abbr.)
7 New country journey
11 Greenland prefix
13 Canadian Island (abbr.)
17 ______ the list
18 Rare DX makes this
22 Test item (abbr.)
24 Operating establishment (abbr.)
25 Turkish prefix
27 Top scorer in DX contest
29 Get on the ______
35 Austrian prefix
36 Eight-land state (abbr.)
38 Revilla Gigedo's prefix
39 Radar image
40 Soviet prefix
42 CW "once more"
45 No good (abbr.)
46 Irish prefix

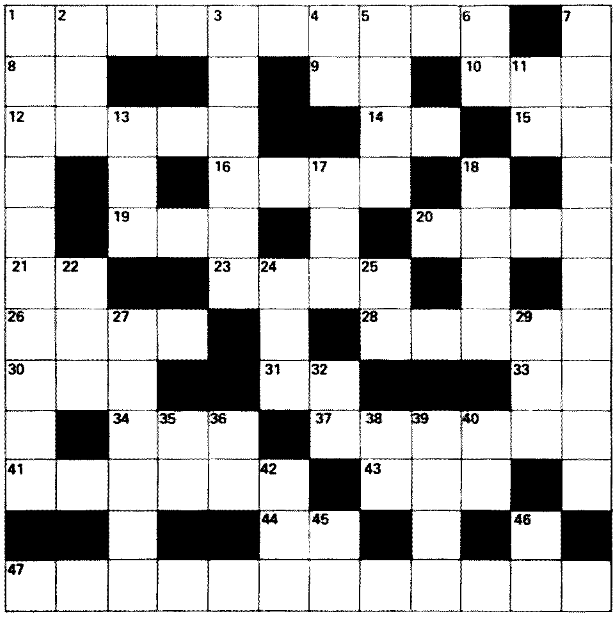

Illustration 1.

ELEMENT 2—MULTIPLE CHOICE

1) On what frequency will you find the Afrikaner Net?
1) 14.230 MHz
2) 14.250 MHz
3) 21.355 MHz
4) 28.510 MHz

2) WWV transmits solar activity bulletins:
1) 12 minutes before the hour
2) 18 minutes before the hour
3) 18 minutes after the hour
4) WWV does not transmit solar activity bulletins

3) We are currently experiencing solar cycle:
1) 21
2) 41
3) 610
4) 20

4) 160-meter DXers have to compete against LORAN generated QRM to find weak signals. Although this nuisance is now on the way out, it still pays to know your enemy. Therefore, what is LORAN an acronym for?
1) Liquid Oxygen Radio—And Nitrogen
2) Long Range Navigation
3) Low Ocean Radiation Aided Navigation
4) Long Radio Antenna

5) Which country listed below does not have a third-party agreement with the US government?
1) Cuba
2) Bolivia
3) Israel
4) Belize

6) Who was the first amateur to snag DXCC on 6-meters?
1) WB2LWJ
2) W2IDZ
3) W6AM
4) No amateur has ever worked 100 countries on 6

7) What phone frequencies are allocated to European (except Soviet) amateurs?
1) 3.6-3.8 MHz
2) 3.5-4.0 MHz
3) 3.5-3.8 MHz
4) 3.7-3.8 MHz

8) The term "master of ceremonies" (MC), when applied to DXing, refers to:
1) A DX operator
2) A QSL manager
3) A person in charge of organizing a DX list
4) A lid who disrupts a net

LETTERS

BASH VS. FAA

The letters in reply to the September article on Dick Bash indicate there are many different views on the propriety of his publishing the questions and answers to the various amateur radio tests.

It is interesting to note that at least two readers had comparisons with the FAA written tests, and I agree in principle with Mr. Remont and his opinion, "You must literally learn the test" in order to pass them.

Mr. Hauser, however, has not done his homework regarding manuals on the FAA written tests. I've identified at least 16 written test guides published by the FAA itself. These test guides cover the pilot written tests from private pilot to airplane transport ratings, the instrument and instructor ratings, plus flight engineer and navigator ratings.

Most of the later FAA written test guides are formatted very similar to the actual written tests, with the subject areas corresponding to those on the test, including questions that may even be word for word with the actual test questions, even to the four multiple-choice answers.

On the last FAA written test that I took, the commercial pilot exam, I believe that 32 of the 60 questions on the test were identical to the ones in the study guide. But bear in mind that the FAA has a slightly different approach to their written tests. The actual test booklet has, in the case of commercial pilot, 600 questions, but the test itself has only 60 questions, and the test sheet given to the applicant indicates which of the questions the applicant must answer.

The FAA written test guides do not have the answers indicated, but at least two aviation ground school operations have published answers and explanations in booklets available to the public. In addition, any pilot wishing to take weekend "cram" courses for an exam can find them within easy driving distance almost any weekend.

Yes, I suppose a person could pass an FAA written exam by memorization. But if a person memorized the 600 questions, surely he would have some understanding of what the FAA requires an airman to know.

But there is one more thing to consider. An applicant for an FAA written test has to produce evidence, a certificate or statement from a flight or ground school instructor that the applicant has undergone a course of instruction preparing him for the exam to be taken. This precludes an airman from simply memorizing the test guide, and then taking the FAA written test.

I hold a commercial pilot's license with multi-engine, land, and instrument ratings.

Sheldon Daitch WA4MZZ
Greenville NC

HORDES OF LIDS

I would like to comment on certain readers' reactions to Dick Bash's interview in *73*: How soon we forget! Anyone who remembers the old (small-format, black-cover) *ARRL License Manual* will recognize Bash's book as approximately the same thing only with more accurate questions/answers. I don't remember anyone taking the League to task for publishing the old-format *Manual* (not to be confused with the new one which might teach theory but does nothing to help you pass the test). And, what of those "schools" that drill you on questions and answers so you can pick up a First Phone? I've met graduates of these "schools" that barely know the difference between ac and dc!

I, like most who took the Extra, noticed that technical competence alone would not get you a passing grade—you needed to know how to interpret the confusing semantics of the test questions.

As for the fears that the Bash approach of licensing will produce hordes of lids, I would like to have those of you who feel this way tune in to the average DX pile-up on the low end of 20m phone. And a lot of these guys are old-timers! You'll notice that the FCC exam says nothing about tact, diplomacy, etc., in operating!

Amateur radio is something that is learned by doing, not memorizing. If you have to memorize to pass the test, so what! Your real learning begins the moment you first press a transmit switch.

Fred Heisler K5FH
New Orleans LA

PASS THE WORD

We departed California on 1 October, 1980, and flew directly to Athens, Greece. The next 10 days were spent clearing customs and obtaining our licenses.

It was only through the efforts of SV1JG and SV0AA that we got our licenses that fast. Anyone going to Greece should apply at least 2 months before arrival.

We got on the air from Crete Island as W6KG/SV9 on 12 October and by 26 October we had 9500 QSOs, half phone and half CW. We worked stations in 142 countries and were on all bands permitted in Greece.

160 meters is not permitted yet for use by Greek amateurs. Operation on 40 meters is limited to 7000 kHz through 7100 kHz, and on 80 meters to 3,500 kHz through 3,600 kHz. We were on 48 hours in the *CQ* World-Wide phone contest and made the highest score for Crete.

The tourist business is a major industry in Greece, and, as a result, all of the islands have great numbers of hotels and everyone in the hotels and shops speaks English.

We try to use Lloyd's call in one country and Iris's call in the next. From here, we go to Rhodes Island in the Dodecanese and will use Iris's call there as W6QL/SV5.

We expect to be on the air almost continuously for 6 months—please pass the word to everyone.

Lloyd Colvin W6KG
Iris Colvin W6QL
Castro Valley CA

FINALLY PASSED

I'm sure that by this time everyone is tired of reading letters about FCC exams and Dick Bash, but if you will permit me, I should like to offer some of my observations and experiences.

After failing the General class exam three times, I was sorely tempted to buy a copy of *The Final Exam*. All that prevented me was the fact that the publication was unavailable. All stores and mail-order companies were sold out and had no idea when new copies would be available, since a revision was in the works due to new FCC exams.

Why was I so tempted? Here's why: The second time I failed the test, I went home and wrote down the gist of every question I could remember from the test. I came up with 47 out of 50. I still failed! My contention, and my biggest complaint, is I failed simply because I had no way of knowing which answers were wrong! Since the FCC examiner will not allow applicants to see their corrected tests, I think I kept missing the same 14 questions!

When I finally passed this week, I missed 9, but I sure couldn't tell you which 5 questions I finally answered correctly! I guess I was lucky to pass at all, but since I was given the exact same exam every time, maybe I just finally eliminated all the wrong answers on the "guess" questions. (Four possible answers, four attempts; the law of averages caught up with me.)

I'm sure that some will say that since I had managed to remember most of the questions, I should have been able to research the correct answers, but the FCC "trick," or what I considered to be vaguely worded questions, defied research. I asked my husband (a long-time electronics and radio hobbyist), Advanced class hams, and even my brother-in-law, who just spent four years working communications in the Navy, and could come up with no answers. I am not an electronic-minded whiz kid, and I guess I'm just lucky the General exam is mostly rules, regulations, and propagation. Otherwise I would be a Novice for life.

I know that there are amateurs who have no use for the "social" operators, but I am proud to be a radio amateur, and though I have great respect for anyone holding an amateur license (especially Advanced and Extras), I feel that I am, in my own "social" way, contributing to the "advancement of skills in

NEW PRODUCTS

NEW AUTOMATIC ANTENNA TUNER

A new automatic antenna tuner for use with amateur, commercial, and government communications systems has been introduced by the J. W. Miller Division of Bell Industries.

Auto-Track Model AT2500 antenna tuners can handle power in excess of 2500 Watts PEP over a frequency range continuous from 3 to 30 MHz. Average automatic tune-up time is 15 seconds.

Front panel switch positions permit the use of three coaxial antenna outputs, one long-wire antenna, and one coaxial tuner bypass. Impedance is 10-300 Ohms. A direct-reading swr meter on the front panel is calibrated from 1:1 to infinity.

The panel meter displays rms power with continuous carrier and automatically displays peak when in the SSB mode in ranges of 0-250 Watts and 0-2500 Watts.

Additional information may be obtained from Curt Henius, *J. W. Miller Division of Bell Industries, 19070 Reyes Avenue, Compton CA 90224.* Reader Service number 483.

FT-480R TWO-METER SSB/CW/FM TRANSCEIVER

Yaesu's FT-480R is a compact SSB/CW/FM transceiver for the two-meter operator. Rated at 30-Watts PEP input on SSB, 30-Watts dc input on CW and FM, the FT-480R covers 143.5-148.5 MHz, with two vfos providing coverage of repeaters not using the standard +600-kHz split which is built into the set. The microcomputer circuitry built into the FT-480R allows ease of operation. For example, when tuning on SSB/CW, the frequency synthesizer automatically tunes at 10 Hz, 100 Hz, or 1 kHz per step (three rates available), or 1 kHz, 20 kHz, and 100 kHz per step on FM. At the flick of a switch, you can zero the display to an even-channel step (when switching from SSB to FM), thus avoiding the nuisance of being a few hundred Hertz away from a "standard" channel when changing modes.

The rig has four memories with priority channel operation, scanning from the microphone, a noise blanker, high/low power selection on CW/FM, and provision for changing frequency during transmission. A matching external power supply, the FP-80, is available for ac operation.

For further information, write *Yaesu Electronics Corporation, 15954 Downey Ave., PO Box 498, Paramount CA 90723.* Reader Service number 482.

The FT-480R two-meter SSB/CW/FM transceiver.

THE 173D PRESENTATION MODEL CLOCK

Benjamin Michael Industries, Inc., has announced the addition of the 173D Presentation Model clock to its line of quartz digital timepieces. The 173D will be of particular interest to those involved in the aviation or communications industries where both local and Greenwich Mean Time (Zulu) is needed.

The 173D is a wall or desk piece which contains two independent digital electronic clock movements. Greenwich Mean Time is displayed in the proper 24-hour military time format while local time is simultaneously presented in a 12-hour format with am/pm indicators. Both large displays are of the LCD type for easy viewing and low power consumption. The 173D features quartz-crystal accuracy along with one year of operation on a single, standard penlight battery. The clock comes in a solid walnut case; the face plate is gold anodized, brushed aluminum.

For more information, contact *Benjamin Michael Industries, Inc., 65 East Palatine Road, Prospect Heights IL 60070.* Reader Service number 480.

NEW TEN-TEC DUMMY LOAD IS AIR COOLED

A new rf dummy load from Ten-Tec is air cooled for clean, easy use around the shack in testing and alignment. It is rated at 300 Watts for 30 seconds. A derating curve is included for using the dummy load over periods of time up to a 5-minute maximum.

Vswr is 1.1:1 maximum from 0-30 MHz and 1.5:1 maximum from 30-150 MHz.

The Model 209 weighs ½ pound and is housed in a 1¾"H × 2¼"W × 6¾"D aluminum enclosure that is perforated with wide slots for free air flow and dark-painted for more effective heat dissipation. An SO-239 coax connector is built in for convenient installation.

For more information, contact *Ten-Tec, Inc., Highway 411 East, Sevierville TN 37862.*

NEW HAMTRONICS KITS

Hamtronics® has announced a new single-channel UHF FM exciter called the model T451. Patterned after the T450 exciter, the new unit is rated at 2-Watts continuous output and is contained on a 3 × 5½ inch PC

REVIEW

CROWN MICROPRODUCTS ROM-116 RTTY INTERFACE AND OPERATING SYSTEM

There are many changes and technical improvements taking place in amateur radio these days, and some of the most profound changes are in the field of radioteletype (RTTY). One could say that the electronic revolution is taking place a little late in RTTY, but there can be no question about it; it is taking place. The noise and aggravation of mechanical RTTY gear has kept many hams from trying out this fascinating mode, but it is time to reexamine the situation. Electronic technology is arriving in force, and there are several manufacturers producing totally silent RTTY equipment that either incorporates a microcomputer on board or interfaces with one of the popular microcomputers such as the Apple, TRS-80, Pet, etc. There are many advantages other than silent operation, however, and the Crown Microproducts ROM-116 RTTY interface and operating system is a perfect example of what can be done with a microcomputer. With no further delay, let's examine this system and find out how easy and, indeed, how much fun RTTY operation can be.

The ROM-116 is an interface board and computer program that allows a TRS-80 microcomputer to operate as a computerized solid-state teletype machine. You connect a transceiver and demodulator to the ROM-116 and the ROM-116 to your TRS-80, and you will be very close to RTTY heaven. The capabilities of the system are almost unbelievable; it appears to incorporate every feature the avid RTTY operator could desire, yet it is not a complicated system to operate.

Like many RTTY systems with video displays, the ROM-116 operates with a split-screen system. Received text is displayed on the top half of the monitor, and a message can be pre-typed in the advanced typing mode on the bottom portion. On the right side of the screen is a continuous display of program status, letting you know whether you are in the receive or transmit mode, in the ASCII or Baudot mode, baud rate, line printer on/off, and a host of other informational items. A quick glance at the status display will reassure you that everything is doing what it's supposed to be doing (or it will warn you that it's not!). Also displayed on-screen is the date and time. This information is simply entered via the keyboard whenever you power-up the system. The date and the correct time will then appear on the screen, and each time the system automatically Indentifies, the date and the correct time will be transmitted. A nice touch!

If you look at the picture for more than a second, you'll realize that the ROM-116 has only one switch: the power on/off switch. That's right, friends, the ROM-116 accomplishes everything under software control. Each of the many functions that this unit performs is selected by typing a code into the keyboard. All commands use a shift and a character, so it is unlikely you'll tell it to do something by accident. If you enter a shift T, for example, the computer will turn on the transmitter, send a CW ID, and then send anything you have typed into the text buffer. Shift K will accomplish the same thing, only a CW ID will not be sent unless it has been ten minutes since the last ID. This thing even keeps you legal!

All the other functions of the ROM-116 are accessed in the same manner. Like many other products in our digital age, you'll have to commit the command codes to memory or else use a cheat sheet that tells you what to enter for a particular function. At first, you might wish that separate switches had been used for each function, but as you grow accustomed to the system, you'll be thankful the ROM-116 uses the direct keyboard entry system for all commands.

With this system, you'll have plenty of commands! The program allows for three memory buffers. If you have a 16K TRS-80, the main text buffer will hold about 7,000 characters. A general-purpose buffer for brag tapes, CQs, and anything else you send frequently holds approximately 2500 characters. Finally, there is a callsign buffer that will hold up to 140 characters. All these memories are held in the computer, not on tape, so you don't have to go through a complicated loading procedure every time you want to send the contents of a particular buffer. If you program all the pertinent details about your station into the brag-tape buffer, you can send that information at any point in the text by typing "shift C". Naturally, while that buffer is being sent, you can continue typing into the main text buffer. As soon as all the information in the brag-tape buffer is sent, the system will send whatever else you've typed in. The callsign buffer works the same way. Anyone who has used a cassette-tape lash-up to store messages will quickly appreciate this ease of operation!

You can, however, use the TRS-80 cassette tape recorder for simple and dependable storage of incoming data, and this brings us to one of the most fascinating features of the ROM-116.

When you initialize the system for the first time during an operating session, you are asked to enter a selcal code. This can be a word, a number, or any combination thereof. Now suppose you leave the shack someday, with your equipment turned on and tuned to 14.100 MHz. If anyone transmits QST, your call, or your selcal code on this frequency, the received text will be written to cassette, following the receipt of four Ns. The system will ignore any other activity that takes place on that frequency. But wait, it gets better! If someone sends your selcal code and the letters ZM, *your* system will switch over to transmit, CW ID if necessary, and send whatever you have typed into the general-purpose buffer. "ZQ" will send 10 lines of "quick brown fox," "ZW" will send "WRU", and "ZY" will send 10 lines of "RYRY". Pretty impressive! When you come home, play back the tape and see what your friends (or enemies) have sent you. It doesn't take too active an imagination to think of all the fun you can have with this.

At this point you probably are worried about hooking up all this glorious luxury. Surprisingly, it doesn't take long at all. I do encourage anyone hooking up this system for the first time to read the manual *very* carefully. The manual is very complete and well written; nothing is left to chance. Although my experience with microcomputers and RTTY gear was somewhat limited at the time, I had no difficulties hooking up the various control cables. Everything went smoothly and worked the first time. Once you have had the system for a while, you might want to examine the back section of the manual and try out some of the goodies that can be done with the ROM-116. Modem operation, TRS-80 as a host computer, and operation on time-sharing systems are just some of the things that are possible.

While the forte of the ROM-116 is RTTY, it comes with a pretty sophisticated CW program as well. Received copy was acceptable, but to quote

Winter Olympics Torch Run

—a one-year perspective

Editor's Note: In the May, 1980, *QST*, one participant's view was presented ot amateur radio's part in the Winter Olympics Torch Relay Run. Due, in part, to more detailed explanations of the project's complexity and the many amateurs' responsibilities, we believe the story presented here lends a different perspective to and perhaps better captures the spirit of involvement of all those who had a hand in this historic event.

Amateur radio made important contributions last year to the Olympic effort at Lake Placid. A great deal of traffic handling and commemorative operating took place with the Winter Olympic Radio Amateur Network (WORAN) and its station, WØRAN. Amateurs also performed admirably during the Winter Olympic Torch Relay Run.

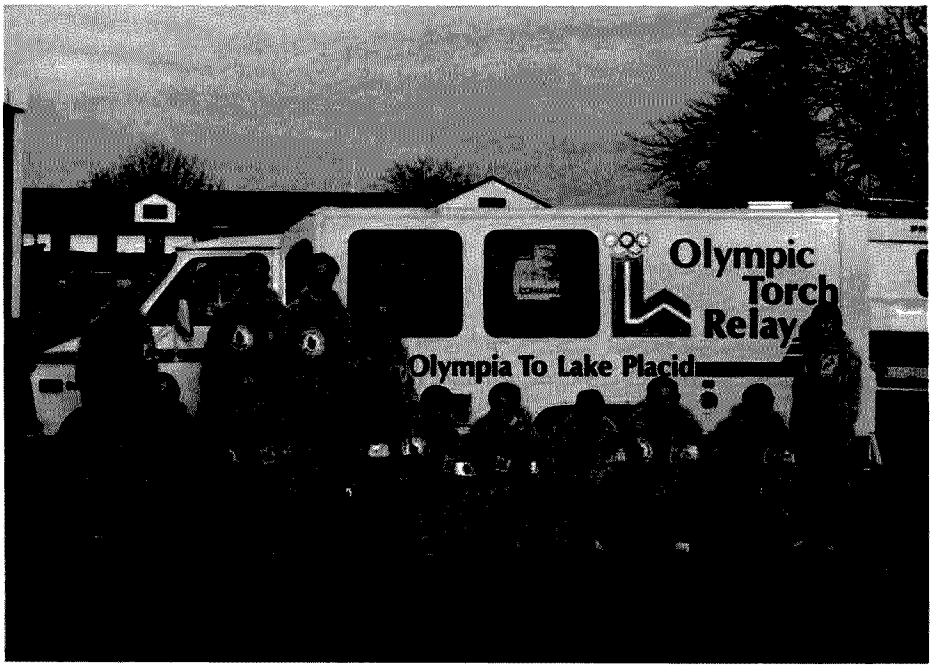

Photo A. The beginning amateur operating contingent in Yorktown poses for the obligatory group shot. Standing from left: W1RM, WA3PZO, KB3HF, KA2DBW, WB1ADL (on right); kneeling from left: WB3HWZ, K2AMU, KA2CNN, WB3EOU, WB3LGC, WA2DHF, WB2VUK, K2AV.

We were among the amateur operators who were chosen to accompany the Olympic Torch from Langley AFB to Lake Placid between January 31 and February 8. There were over 1,000 miles and nine days of extraordinary operating, mostly on VHF. It demanded all the skill and combined experience we had in contesting, traffic handling, and high-speed tactical communications. It was something none of us will ever forget, and something the entire amateur community can be proud of.

Early in 1979, the Lake Placid Olympic Organizing Committee (LPOOC) approached the ARRL. They needed experienced communicators to provide reliable communication for the vehicles involved in the Torch Relay Run. The Run had been organized, in an attempt to publicize the coming of the Olympics to the US and to Lake Placid,

s a combined public relaons and educational efort. It would be the first me the genuine Olympic ame, kindled in the temle of Hera from the rays of ne sun in Olympia, Greece, ad been on American soil he earlier Olympic flames lisplayed in this country vere ceremonial dupliates). Ham radio was re,arded as the most approriate source for trained perators for a number of easons, not the least of vhich was the fact that iams, like the athletes, are killed amateurs who sacriiced a great deal of time ind money for the thrill of ublic service contribuions and competition.

It was a tall order to fill. Over 75 people in 11 veicles, some of which would be as far as 100 miles apart, were needed to keep in touch constantly to coordinate their many and varied activities. Each little town on the Relay's route had planned its own ceremony to honor the passing of the torch, and these ceremonies needed to be coordinated with the scheduling, the program, and the safety requirements of the moving caravan within which the torchbearers were to run. This coordination would have been impossible through any medium other than ham radio. Lunches had to be found and picked up, and then the vehicle with the lunches had to find the moving caravan again. Ham radio had to deal with scouting for fuel, with command and policy communications, vehicular repairs, rest-room stop arrangements, and liaison with state and local law enforcement agencies. Literally hundreds of events each day had to be controlled in a coordinated fashion.

Safety communication was our highest priority. With eleven vehicles on two-lane roads in curving, hilly terrain, allowing vehicles to pass around the caravan became a problem. If the torchbearers stumbled, the entire caravan would have to come to an immediate halt to avoid running over them. Crisp, sharp—and secure—communications clearly were required. Bad weather had to be anticipated—but we were lucky in this potential problem area.

The operators who were chosen to accompany the torchbearers and staff were selected on the basis of their experience in contest operating (which bore many similarities to the type of operating we would be undertaking), traffic handling, and walkathon- and marathon-type operating. It included many with experience handling communications for the New York City Marathon, including the communications coordinator for that event, Steve Mendelsohn WA2DHF. The hundreds of amateurs who provided invaluable support communications along the route while the caravan was in their area are regrettably too numerous to be mentioned. The traveling operators were drawn mostly from the upstate New York, northern New Jersey, New York City, Baltimore, Philadelphia, Wilmington, and southern Connecticut areas.

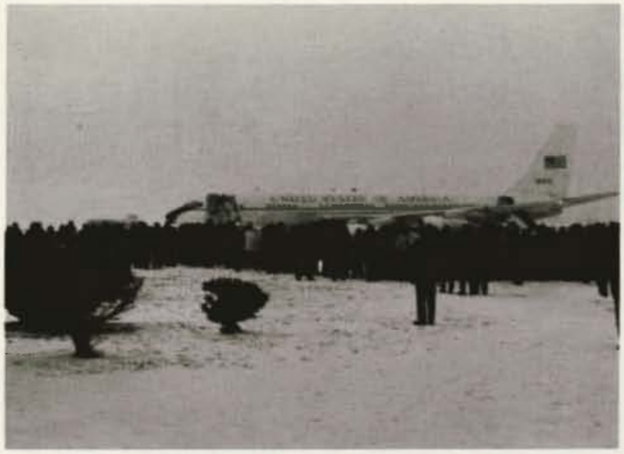

Photo B. The early-morning arrival of the Olympic flame, during a snowstorm, in a State Department aircraft similar to Air Force One, on January 31, 1980, at Langley Air Force Base.

The runners numbered 52—one from each state plus one each from the District of Columbia and Lake Placid. Evenly divided between men and women, they were chosen from

Literally scores of amateurs and their families along our route helped in various support capacities, performing tasks ranging from repair of broken rigs to transportation of emissary runners from place to place, to donations of equipment for our temporary use, to relay from VHF to HF to maintain our contact with WORAN and Link Nixon in Lake Placid. Although it would be impossible to acknowledge all of those who played important roles in this effort, here are the calls of many without whom the traveling team would have been isolated and crippled.

among 6000 applicants on the basis of personal interviews, essays, and their running ability. They ranged in age from 15 to 54 years old. They were organized into four teams of 13 runners each, with two teams assigned running duty each day and the two off-duty teams given emissary functions. The emissaries traveled ahead of the caravan making public appearances at churches, schools, and service and social clubs, speaking about the Olympic spirit and the Relay Run itself. Officially, each runner ran between three and five miles each day, but many frequently ran alongside the torchbearer or ran after we stopped for the night.

Like the hams, the runners made the effort required for the run at their own expense, receiving only a uniform, meals, and lodging for the duration of the run and of the Olympics. Additionally, and perhaps most prized, were the Olympic participation medals we all received, along with certificates of appreciation. Runners and hams alike either took extended vacation or leaves of absence from their work to take part in this rare opportunity. Any distinction between the two groups soon faded in view of the shared excitement and sacrifice and was further eroded as the runners watched the amateurs in operation and the hams watched the runners in all weather, on all terrain, bearing the torch to Lake Placid. A great, solid bond of mutual respect developed after only a few hours.

Following personnel selection, there was a period of discussion and practice. The runners got together in Lake Placid in the summer of 1979 to practice the technique they would be using and to get to know one another better. The hams weren't so lucky where lead time was concerned. After an initial organizational meeting on the hard, cold floor at Rockefeller Center in Manhattan—to which many drove long distances—we practiced with a small group of the runners. This practice was a test of the last day of the Relay Run from Fort Ticonderoga to Lake Placid on the Albany East route, with a day-long recap and critique over the weekend of December 8-9. This full-scale test was invaluable for the technical and organizational lessons we learned there. Without it, we would have been ill-prepared for the coming trial.

We learned that because of the volume of traffic on the circuits, we would have to plan for two nets in simultaneous operation. We chose 2 meters due to the availability of equipment, although later we were to use 220-MHz simplex for part of the operation. One net would provide a low-power circuit for internal caravan safety and coordination on simplex. The other would provide a circuit for the external group of vehicles (described below), using higher-powered rigs and, where possible, using repeaters. Because of the proximity of the two nets in the same band, there were, inevitably, problems with desense and FM sideband noise.

Luckily, Dick Frey WA2AAU joined the practice group at the last minute. A competent home-brewer and technician, Dick constructed solutions to the desense and sideband problems in the short period between the practice and the real thing. He planned and built a narrow passband filter—a very sharp one—with a bandpass from 144.250 to 144.450 for use with the low-power internal frequency transceiver. Additionally, he procured and critically tuned a resonant cavity setup for use with the external net high-power transceiver, to notch out the 144.2-144.5 band. In use for almost three weeks under very harsh and demanding operating conditions, they performed flawlessly and were the ideal answer to our problems. Without Dick's effort, his advice, oodles of his own equipment (220- and 2-meter rigs and antennas), and his investment in time, gasoline, and money in this effort, it would not have worked out.

Dick's equipment was used with two UV3s loaned from Drake for the event, both of which performed perfectly in the demanding environment. Side by side, both on 2 meters, just 18 inches and 1½ MHz away from one another, with only 3 to 4 feet separating antennas on the roof of the vehicle, intermod and desense between the two rigs was so insignificant as to be almost unmeasurable. We were very pleased with both Dick's filter setup and with the performance of the Drakes. That company was also generous in the loaning of a TR7 with matching vfo and transmatch for use in our HF setup, described below.

Other companies also loaned various items of equipment for our use. Kenwood generously loaned four of their new TR-2400 synthesized handies with chargers, Tempo came through with four of their dependable S-1 handies with chargers, and Larsen loaned at least a dozen quarter-wave mag-mount antennas for 2 meters. Needless to say, synthesized equipment was the order of the day, and we all brought along what we owned if it could be put to work in the effort. Longer-range vehicles needed 5/8-wave antennas, and they were supplied by members of the team who owned them. Mobile rigs ranged from Heathkit 2036s to Icom, Yaesu, KDK, and Tempo equipment. One Yaesu FT-207R also made the trip in the hands of KA2DBW, and in the police liaison position it performed flawlessly on 75% charge, 200 mW, 15% duty cycle for 8-10 hours.

The eleven caravan vehicles—and their corresponding communications

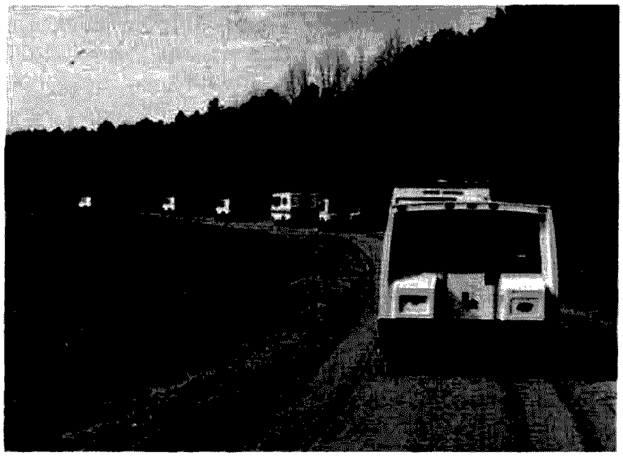

Photo D. *The arrangement of the caravan during a practice, showing the order of the vehicles, with the torchbearers visible in front of the second (Command) vehicle.*

Photo E. From left, WA2DHF and KB3HF after about 30 hours as net controls.

positions—all had specific duties to perform. They were organized into an internal and external group. In order of their travel, the police vehicle came first. (We called it "PD" on the air; although we identified every ten minutes, the circuit was so busy that we referred to vehicle designations rather than callsigns.) Usually PD was a state police car in which one of our team members was placed to provide liaison between the caravan and the state police and, through their communications system, usually with local jurisdictions, also. This vehicle changed periodically, of course, not only at state or barracks boundaries, but also as different patrolmen were relieved, since our hours far outlasted their shifts. This fact, and their prohibition against the installation of any electronic gear not under their control, required the use of an op with an HT. In some states, getting the state police to agree to our placement of an op in their vehicles was like pulling teeth. But for both the liaison function—indispensable in itself—and for safety reasons, it was a requirement of the Director of the Run and, ultimately, every jurisdiction agreed.

Usually, the vehicle behind PD was the Pace vehicle. Its personnel were responsible for keeping the pace for the very tight schedule under which we were operating and for navigating the course from a detailed computer printout. Although the runner set the pace, the personnel in this vehicle could suggest, through their PA system, that the runner pick up the pace or slow it down. They communicated the position by checkpoint number to the Director at every checkpoint and gave speed instructions to the other vehicles. They also were responsible for the calculations of ETAs at upcoming events. All of this, of course, made for a rather high volume of traffic on the circuit both to and from this vehicle.

The torchbearer with his/her accompanying entourage, often including local guest runners and, sometimes, flagbearers (and even the occasional ham!), followed the Pace vehicle. Here a very delicate compromise had to be struck. Barred from Interstates because of our 8-minute-mile pace, we were traveling on two-lane roads. Oncoming traffic, only a few feet to the runners' left, sometimes passed slowly, rubbernecking, but more often apparently was oblivious to our slow-moving caravan despite the rotating police beacons. We were moving closely together, and off as far to the right as the shoulder would allow, but a great deal of traffic was backed up behind us most of the time. We frequently were pulled off the road by the police (when there was room to accommodate the entire caravan) to allow this traffic to pass, but we had the frequent problem of the maverick crazy driver who decided his need to get around us was greater than his own life's value.

Usually, it seemed, these maniacs pulled out on curves. Soon discovering that our long, tight caravan and oncoming traffic prohibited their passing, they would abort the pass halfway into it and try to squeeze into our group. We could usually accommodate these turkeys with minimum angst; more dangerous were the times when the driver would use what to him appeared to be the only available clear spot in the caravan—which, of course, was occupied by our torchbearer.

For this reason, we kept the Pace and Command vehicles, with the runner(s) in between, as close as possible. This brought up another safety problem: If one of the runners stumbled, the Command vehicle could (and on at least one occasion almost did) run over the people involved. A delicate balance existed. Our best drivers followed the runner, and transmissions on the internal net were kept as short as possible to allow immediate notice of either unauthorized passings or of stumbling runners.

The Command vehicle served many functions. With a customized fiberglass Trans-Sport body on a Chevy van chassis, primarily it was transportation for the Technical Director of the Relay (or, on the Albany West route, the Assistant TD) for whom we provided eyes, ears, and mouthpiece. The two nets were controlled from this vehicle, which contained the two UV3s, cavities, filters, amplifiers (to 100 W for the external transceiver), and HF gear, on a table in the center of the rear

Photo F. The first torch hand-off with full ceremony in a hangar at Langley AFB.

area of the van. The NCS operators sat in what we called the "Hot Seat" for the obvious reason that this was the most demanding of positions. They coordinated the movement of all caravan vehicles, relaying pertinent information to and from the TD, exchanging information and providing relays between the internal and external nets, and frequently (but inadvertently) by necessity acting as the TD in his absence, making snap decisions.

They were assisted by a rather complex home-brewed audio setup through which either op could switch in either or both of the nets using stereo cans. They also used a magnetic chalkboard with "shrimpboats" to keep track of vehicle placement. The hot seat was claimed by five operators for the entire run, who rotated into and out of the different nets. They were WA2DHF, W1RM, K2AV, KB3HF, and WA2SPK. By necessity, they frequently had to stay glued to their positions for twelve to sixteen hours without a break—sometimes longer—and had to be dragged out in burlap sacks and resuscitated with smelling salts.

Big Macs, Whoppers, and other assorted junk foods also served as first aid on the relay. Hams are, for the most part, notorious for their eating habits, and many diehards on the team refused to partake of the available fare. This consisted of oh-so-healthy vegetables, fruits, soups, lots of prunes, and, above all, "fiber." All of this was, of course, concocted with the needs of the runners in mind and included nary a shred of red meat for days on end. The chant which most frequently broke down net discipline on our circuits was "Junk food! Junk food!", along with the sound of growling abdomens in the background. Luckily, the frequency of the internal simplex net was a closely guarded secret, ostensibly for reasons of avoiding QRM, and this was not heard by the general public. We hope!

Command was, to say the least, crowded. With all the equipment, wiring, papers, and human beings (up to seven at a time), it became the hell-on-wheels of the caravan. There were heater problems in the vehicle, to add salt to the wounds, and the net controllers and staff in the vehicle remained bundled up throughout their shifts. Upon entry to this vehicle, one was immediately reminded of an igloo, smell and all.

Two Pace Arrow RVs served as transportation for the 26 athletes running each day. Although their designations changed during the Relay, they were known basically as the on-duty "Runner" and off-duty "Walker." Each carried 13 runners and took four shifts of on-duty and off-duty time each day. Walker was for the resting runner crew and occasionally would travel in the caravan (behind Command), but usually would go ahead to a designated checkpoint and wait for the caravan to catch up, at which time its designation might change and its crew would go on duty. The communicator in this position had an easier time than most, and it was frequently used as a resting slot for the radio ops. He or she was responsible for the relay of the next team exchange checkpoint, among other minor duties.

Runner was kept busy exchanging running teams with Pace and jumping ahead several miles to the next exchange point. The op in Runner was kept rather busy coordinating personnel exchanges, getting a fresh team ready and out, taking head counts of those coming aboard, keeping the athletes informed about ceremonies and schedules, and communicating with Command during the leapfrogging, for safety coordination.

Walker usually was followed by a tail PD, sans operator, and was sometimes followed by components of the external vehicle contingent temporarily traveling as part of the internal caravan. If there were local hams traveling with the caravan to help provide local liaison and relay on HF, their vehicles would follow the last of the official vehicles and precede the tail PD escort. This happened frequently, and the help from local hams was invaluable to the effort.

In the external contingent, the Convoy vehicle, another Chevy Trans-Sport van, provided transportation for the Convoy Director and the Food and Accommodations Coordinator. They were responsible for the procurement and conveyance of our meals and the advance work concerned with our accommodations. We were fed well (the above comments notwithstanding) with four square meals or more each day—about one meal every three to four hours—and usually there were lots of leftovers. The fare was difficult for some of us—especially those from NYC used to munching on famous Nathan's hot dogs—but it was thoughtfully prepared and it even, ah, well, it was *good*! Liking carrots can be learned. And rosy cheeks are cheery. Many of us now have healthier eating habits (and a few of us have even taken up running seriously). Often, the food was prepared by generous residents of the towns through which we passed, organized by church groups, Rotary, Elks, or Lions clubs, or, on some occasions, the military. Sometimes it was purchased by the Convoy Director out of her budget; on only one or two occasions did we have to pay for it ourselves.

Most of the meals were arranged for weeks or months in advance of our arrival. Sometimes we were on such a tight schedule that the lunches were passed in through windows by volunteers running alongside the caravan. The Convoy vehicle became, after a few days, a sea of sloshing soup and vegetables on the inside. Smelly and fun, but it threatened to short out the ham gear in-

stalled there! Hip boots and rubber gloves were in order, especially during the first two days which were nonstop for over 40 hours with no opportunity to clean up until after more than a dozen different meals. The convoy crew, during that first leg from Yorktown VA to Baltimore, affectionately called themselves the "Go-Fer Squad" and almost seriously considered never eating again.

A large European-style touring bus transported half of the running team—the 26 not running on any particular day—to the next day's overnight stop, ahead usually by 85-100 miles. Although for the first day an operator was placed in this position as a communicator, it was found not to be necessary. This vehicle also was responsible for transporting some of the emissary runners to their speaking engagements or ceremonies further up the route of the Run.

The event engendered a great deal of interest by the media, and we anticipated a certain amount of need to accommodate its representatives. What we were unprepared for was the amount of coverage we were to receive. It seemed to be due to the connection the public felt with the symbol of the international Olympic flame and patriotic sentiment, even nationalistic fervor, generated by the USSR's invasion and occupation of Afghanistan and the holding of American hostages in Iran. The media, apparently as taken by surprise as we were, quickly realized the sensational side of this story and it became the content of—and set the tone for—most of the articles written and programs aired. Of course, this was commonplace during the Olympics themselves, especially where it concerned the incredible victory of our hockey team over the top-rated USSR team, but our passage marked the first expression of this popular ground swell of opinion.

We tried to prepare for this onslaught with another Pace Arrow set aside especially for the purpose of public relations. From this vehicle, which was usually ahead of the caravan by as much as three or four hours, press kits were dispensed, questions were answered, and interviews were arranged between the runners and the media representatives. The communicator here acted as a relay for specific questions directed back to the caravan and the TD on the external net and for relay of ETAs and names of the runners involved at any particular time from the TD to the PR staff. Because of demands from the press passed along to the operator, this position frequently became rather high-pressure and busy, especially in the larger metropolitan areas.

Although many attempts were made to include word of the involvement of amateurs and amateur radio in the event, the PR staff was not sympathetic to our requests for publicity regarding our support. This attitude did not reflect the general sentiment of the runners or the rest of the Relay staff, fortunately, but it did mean that many opportunities for positive PR regarding our role were lost to personalities. There was little notice of our effort by the national or local media. WA2DHF appeared on the front page of the *New York Times* on February 5, but neither the caption nor the story included his function, his role, or his name, or identified that hand-held, funny-looking box with the rubber gizmo. Our uniforms, however, did include the ARRL logo and a large patch produced for the event with "Olympic Torch Relay Run" on the top and "Amateur Radio" on the bottom in large block letters. All of the vehicles bore "Amateur Radio" placards in every possible window.

Photo G. KA2DBW on the job in her hometown, New York City, on February 4.

Many of the questions the media asked involved the technical aspect of the torch itself. It was a specially-designed instrument constructed specifically for relay runners by an American of Greek ancestry, Jim Kalamaridis. Some 132 of the devices were custom-manufactured for the event. Charged with propane, they had a life expectancy of about 40 minutes per charge, and, theoretically, could withstand a wind of 80 mph. In practice, however, we had frequent flameouts, and the original flame was maintained in a series of miner's lamps, some with a hole drilled in one of the glass panels to accommodate a sparkler to transfer this original flame from lamp to torch. Each lamp had a life of about four to six hours per propane charge, and Jim and an assistant were kept busy almost full-time simply charging and maintaining the torches we used. The flame we saw in Lake Placid, which was trotted up to the huge gas flame bowl at the ceremonial stadium by Chuck Kerr, one of the torchbearers, was the very same flame lit in Olympia weeks before and carried by our combined team up the coast of the US. If the flame went out, it was relit from one of the backup miner's lamps; we didn't just flick our Bics.

Wondering how to get an Olympic torch across the Atlantic? The Air Force lent one of the aircraft used for Air Force One—a KC-135 (military designation for a Boeing 707)—for use in conveying this most honored of guests to our nation. Inside the plane, sitting in Jim Kalamaridis' lap and on the floor around him, were the six miner's lamps, all burning with the flame lit at the temple of Hera. The plane landed at Langley AFB on the morning of January 31 and taxied to a full multi-service Honor Guard in a huge hangar, in the midst of a snowstorm.

The Torch Arming Vehicle (aka "Torch" on our circuits) was used to transport the torch technicians and their gear for the long and grueling trip. After dark, this vehicle could be recognized by the light of the frequent spontaneous propane flares issuing from the open doors of this Santana van—reminiscent of the aurora borealis. The commu-

Photo H. In gratitude, the amateurs were permitted to carry the torch on the frosty last day, a few hours outside of Lake Placid. Here KA2CNN is carrying the flame.

Photo I. WB2VUK with Brooke Newell, one of the ceremonial coordinators, at a ceremony site in upstate NY, using one of the Kenwood TR-2400s to mike her as she describes the layout of the ceremony to the TD in the caravan a few miles away. Note the collapsible whip antenna which was used instead of the rubber ducky for added range.

nicator in this vehicle, besides being preoccupied with seeking air free of the stench of propane, was responsible for notifying the torch technician in case of a flameout or torch failure.

It seemed as though every town, no matter how big or small, had some sort of welcoming ceremony prepared for us. This usually involved a high school band attempting to play the rather difficult Olympic anthem and always botching it. We heard that piece in every possible key, in every possible arrangement—even with a disco flourish. This was followed by speeches—sometimes interminable—from local dignitaries or politicians, and then words from our ceremonial coordinators describing the caravan, the function of each of the passing vehicles (especially helpful for the often-confusing passage of the advance vehicles), and an attempt to educate the crowd about our safety requirements, because the crowds were frequently large and under-controlled and we were coming in in large vehicles.

This usually was followed by a short speech from the incoming or outgoing runner, and then the torchbearer would arrive, make a handoff, the caravan would continue, and, perhaps, the incoming runner would stay to speak a little more as the caravan moved out to the next stop. We had been informed of, and could plan for, about half of these events. The rest had either been organized by groups or communities at the last minute or were spontaneous gatherings of people. Frequently involving many hundreds of people, they were completely without any authoritative control and overran the roadway. The caravan drivers, the TD, the staff, and most of all, the runners, needed to know what they were getting into on these occasions. Somehow, these unplanned crowds had to be quieted, informed, organized, moved back, and opened up for the arrival of our caravan.

The runners had a special need to know what they were getting into because of a phenomenon we did not anticipate. They suffered from a certain amount of "tunnel vision" due to the exertion, the weather, the excitement, and the adrenaline. They frequently needed to be led in by another runner at the ceremonial site, or they would trip on a curb or bump into a member of the public in the crowds. Their torch also was a fire hazard, and holding it up high gave a runner an effective height in excess of 9 feet. The job of the ceremonial coordinator was to pre-brief the caravan from an advanced position relative to obstacles, pathway, crowd quantity and mood, clearance, fire hazard, etc. This information was passed along to each driver in the caravan and also given to the runner by PA from the Pace vehicle. Because of the involvement of the ceremonial coordinators with the local groups sponsoring the ceremonies, the job of sizing up the ceremony situation frequently fell to the communicators themselves. The communicator also was responsible for the relay of ETAs to the local groups so they could plan the timing on their stages.

After the caravan and torchbearer had passed through the location of the ceremony, after it was all over, the ceremonial vehicle driver waited to collect all of the personnel. Then it was off down the road to catch up to the caravan, and—often with a very high-speed police escort—to leapfrog the caravan and make the way ready for it at the next ceremony site. On our busiest day, there were 21 such ceremonies to coordinate. Although not the most difficult position, it was a high-pressure communicating position and perhaps the most exciting, since the op was able to view the ceremonies themselves and some of them were quite well put together.

One problem the personnel in the ceremonial vehicle did not have was that of the visual and psychic effects of day after day of travel at 7 or 8 mph. We all functioned under conditions of great pressure and constant demands. Breaks were few and far between, and we were almost constantly in a state of swollen derrieres and bladders. Hallucinations were one result of the slow movement

of the passing panorama (which also made for prolonged nulls on VHF); some of us imagined having seen trees grow. Radio traffic was constant and exhausting, of a nature only contest operators may be familiar with, or those with military backgrounds. Calls for the particular vehicle for which one was communicating always seemed to come during that once-in-an-hour period of dropped guard. The circuits were so busy that even a few seconds of dead air were cherished as the most precious of gifts.

Because of the unplanned ceremonies, constant changes in plan, variations from the published Technical Manual (TM), and inaccuracies in the TM itself, on the first day out W1RM nicknamed the entire operation "Rollerball." Those who've seen the motion picture will know what we're talking about: It describes a game in which the rules change every quarter, getting tougher and more violent. The entire script of the operation literally was changed from minute to minute. So pervasive was the use of this nickname that WR3AFM, the home repeater of one of our NCSs, KB3HF, changed its ID for us. When we arrived in their area, its CW ID was spelling "Welcome Olympic Torch de WR3AFM." When we were awakened the next morning and tuned in the repeater again, it was signing "de WR3AFM Rollerball." The NCSs referred to themselves after that first 40-hour stretch from Yorktown to Baltimore as "Rollerball Control."

In the December practice, the HF setup received a limited workout with K2GDX, the coordinator for WØRAN, in the Lake Placid area, and it was thought that we would be using HF links directly from the Command vehicle to WØRAN in Lake Placid during the relay. As it turned out, this equipment was hardly ever used because of the huge volume of tactical and safety-related traffic in the Comm van, the long operating hours, because of Rollerball, and because of the relatively low priority of traffic for HF. Instead, operators from the local area traveling with the caravan or in contact with the caravan on the external VHF net served as VHF-to-HF relays. Dozens of highly competent ops were involved in this particular effort. Without them, the caravan would have been virtually cut off from the LPOOC except for the overworked and extraordinarily unreliable mobile telephones installed in the Command and PR vehicles.

Working the HF link with WØRAN required the patience of old Job. We were bothered constantly by all the many and varied incarnations of the persistent QRMer, from hams who offered to help and ended up hindering (some have to learn to listen more and transmit less unless they're certain they can help), to ops seeking commemorative contacts during traffic operations, to real "sickies" with swishing vfos and persistent strong carriers. The patience, persistence, and experience of HF ops involved did prevail, however, and the traffic was passed.

Warren Gibson WA4CCK provided just one example —perhaps the most dedicated example—of the dedication and sacrifice so many of the local hams offered. Experienced as a traffic handler on many nets, he joined us in Yorktown as the amateur coordinator for Virginia, driving a station wagon full of a rather extensive HF and VHF setup. He accompanied the main caravan for its most

Photo J. Two of the torchbearers on the road, somewhere in upstate NY.

trying days, the first ones, from Langley AFB to Baltimore, nonstop for over forty hours of driving and operating relay, and also the third day, from Baltimore into a grand ceremony on the steps of the Capitol. He left us in DC amid cheers of gratitude from all members of the traveling communications team, having served as an invaluable shoehorn on countless occasions.

We even got some "maritime mobile" operating into this thing. Steve WA2DHF is a radio operator for the Naval Reserve and was chosen to accompany the torchbearer on a seagoing journey aboard a Navy landing craft from Langley AFB to the Yorktown pier—about 2½ hours in the water—using a Tempo S-1 all the way. For the startup of the Relay overland, he joined Pete Chamalian W1RM in the Command vehicle. Also present for the startup were ourselves; Bob Fern K2AMU; Jeff Young KB3HF; Jim Arnold WB3EOU; our coordinator, Bobbie Chamalian WB1ADL; Steve Shearer WB3LGC; Guy Olinger K2AV; Paul Vydareny WB2VUK; Bob Josuweit WA3PZO; Bob Strickland WB3HWZ; and, previously mentioned, Warren Gibson WA4CCK, in his own vehicle.

Joining in Princeton was Gary Kantor WA2BAU. In Albany, the route was split: Communities to the west of the officially planned route had raised funds on their own sufficient to allow the personnel and vehicles to split after the Albany ceremony, permitting 26 runners to go northwest through the Adirondacks while the "Albany East" team took the other half of runners on the original route. A tremendous ceremony involving thousands

of spectators, with disabled veterans holding the torch with the torchbearer for the last couple of hundred feet, greeted us all in Albany. Governor Carey, following a moving speech of welcome, oversaw the lighting of two torches from the original incoming torch, and two runners left the plaza, one bound northeast, the other northwest, both destined to meet a few days later in Lake Placid.

In Albany, additional vehicles and staff personnel were added to take up the slack and to provide coverage for the scores of ceremonies awaiting us on both east and west routes. The closer the runners got to Lake Placid, the more identification local communities felt with the Olympics and the larger and more frequent the individual ceremonies became. Five traveling operators drawn from the Albany/Troy/Schenectady areas were added to the communications team: Joe Krone WA2SPL; Dennis Connors WB2SPK; Armand Canestraro WA2EQW; Dan Marcella KA2DVK; and Guy Kitchen WA2SPE. Stationary support and east-with-west relay was provided by Dick Frey WA2AAU.

On the last day, during our approach to Lake Placid and facing the prospect of breaking up the group which by this time had built up an incredible bond of solidarity, the amateurs and support staff were afforded a rare privilege: We all were given the opportunity to carry the torch for a few minutes. On a clear stretch of Route 32 south of Saranac Lake, we left our vehicles, one position at a time, and in moments none of us would ever forget, we bore the flame north to the Olympics. The feeling each of us had, holding this sacred flame and running it north, was indescribable. Wonderful. As we ran, the runners cheered us on and our fellow ops took pictures by the dozens.

On the night of Friday, February 9, after rollerballing for nine days and nearly a thousand miles, we reached our goal. The east and west route torches had to meet in downtown Lake Placid at exactly the same instant. Timing was crucial and the circuits began to fill with almost nonstop checkpoint and ETA advisories between the two caravans. One caravan with torchbearer could not be kept waiting at the end for the arrival of the other. The crowd was huge, and the media were out in full force as we played our last hot and heavy round of rollerball. This was the biggest and last task for the communications team, and we knew we had to get it right; this was the event the participants would remember more than any other; it was our crucial test.

We did it. The timing was flawless, and not a dry eye remained in the entire team, runner, ham, or staff member. We had reached our destination. Looking back, despite some mistakes, some personality conflicts, and numerous technical difficulties, we had performed our job through the most incredible experience of teamwork any of us had ever had. When the two torchbearers met in Lake Placid that night, the elation and feeling of accomplishment that swept through the team made the stress, deprivation, and hardship of nine days on the road well worth the effort. We're looking forward to working together again in 1984 in Los Angeles. Perhaps we'll see you there! ■

New Life for Old Klystrons

—tips for microwave experimenters

What? Use a vacuum tube in this modern era of solid-state electronics? Reading about Gunn diodes, Impatts, and other such exotic devices is fine, but with the exception of the Microwave Associates Gunnplexer, there are no complete solid-state oscillators available to the amateur.[1] This became very apparent while I was trying to put together a receiver for direct reception of television signals from geosynchronous satellites at 3.7 to 4.2 GHz.

A multi-stage oscillator-multiplier chain was ruled out because of insufficient time. If everything works, the final receiver might have a solid-state local oscillator, but then again, maybe not—why discard a working circuit? Reflex klystron oscillators of the 723 and 2K25 class (see Fig. 1) have been available on the surplus market for over thirty years. Output frequencies from below 3 GHz up through 9.6 GHz are currently available with output powers in the neighborhood of 10 to 150 milliwatts.[2] These klystrons have found applications in the past in polar-plexers and as pump oscillators for amateur and commercial parametric amplifiers.[3,4,5,6] The tubes listed in Table 1 are similar in construction and can be mounted in octal sockets that have had pin 4 removed and bored out with a number 24 drill. The output is via the small diameter, rigid coax line which terminates in a short probe. The probe was used to directly excite a waveguide or was capacitively coupled to a coax cable.

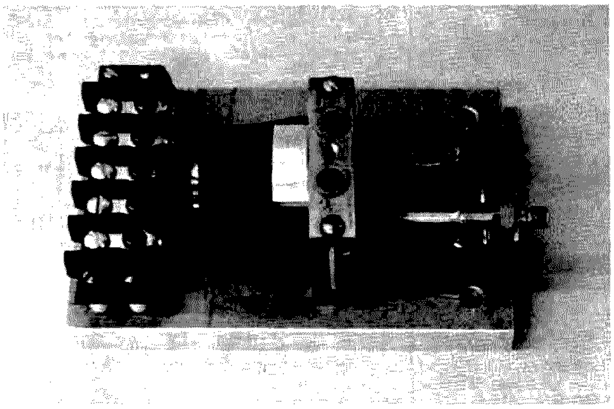

Photo A. 726A klystron with coax output and terminal strip.

Tube	Output frequency(GHz)	Output power(mW)
726C	2.7-2.96	100
726B	2.88-3.18	150

*Improved version of 723A/B, both of which can reach 10 GHz by stretching the cavity.[5]

Table 1. Reflex klystrons from 2.7 to 9.66 GHz.

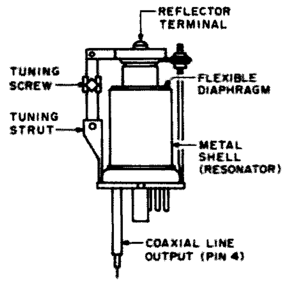

Fig. 1. 723-class reflex klystron.

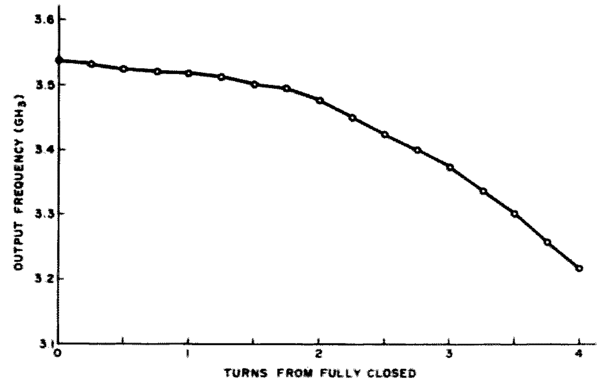

Fig. 2. Output frequency of 726A as a function of tuning-screw rotation.

In normal operation, the tube shell is operated at 250 to 300 volts above ground. This puts the output cable, which is connected directly to the shell, at a hazardous potential. However, by operating the cathode at a negative voltage, the shell and output cable can be maintained safely at ground potential.

The photograph shows a 726A klystron mounted on an aluminum plate for use as a local oscillator for the satellite receiver. The tube is clamped by a simple split block to allow conduction cooling and provide a mechanically stable support. This degree of mechanical rigidity is not required but was convenient in this case. Also, free-standing operation with convective cooling is alright. The oscillator covers a measured frequency range of from below 3.2 GHz to above 3.5 GHz.

The output frequency of this particular tube as a function of the rotation of the tuning screw is shown in Fig. 2. By changing the reflector voltage, the output frequency could be shifted electrically plus or minus fifteen megahertz from the mechanically set frequency. This FM characteristic can be used for fine tuning or for a form of afc with simple circuitry.[7]

The output probe is terminated with an SMA connector. A cross section of the connector assembly is shown in Fig. 3. A BNC connector could be used with equal success. The output probe center conductor is clipped close to the insulated sleeve, the ferrule is slid back onto the probe. Then the center conductor is soldered to the coax connector. Following this, the ferrule is slid forward, screwed to the connector with two 2-56 screws, and then sweat-soldered to the probe.

Power leads run from a barrier strip to the tube. Connections to the tube are made with a modified octal tube socket—see Fig. 4. While normal operation requires −300 to −700 volts at zero current for the reflector, operation at reduced potentials and output powers is not only possible but desirable in that power dissipation and heat are reduced substantially. This adds to the tube life-expectancy.

Operation has been at cathode voltages as low as −150 volts at 10 mA and reflector voltages of −150 to −300 volts. With a −300-volt cathode supply, output powers in excess of 60 milliwatts were readily obtained. With a −150-volt cathode supply, the output dropped to about 4 mW, which is still sufficient for use as a local oscillator. Even at the high powers with only free convection cooling, life expectancy is high. Tubes pulled out of service after hundreds of hours of service and stored thirty years or more are still operating.

A word of caution: The reflector must *never* become positive with respect to the cathode. If it does, it will draw current, heat up, and outgas, ruining the tube. To prevent this from occurring, merely connect a rectifier diode between the cathode and reflector as shown in Fig. 4.

The theory and operation of reflex klystrons is available elsewhere and therefore is not covered here.[8,9] What I hope I have accomplished here is to remind other amateurs of the availability of reflex klystrons as packaged sources of microwave power that are rugged, cover a wide spectrum, and are economical.■

Add RTTY to Your Repeater

—voice operation is preserved

The consensus was that we needed a RTTY repeater in Corpus Christi. It also was decided, on that Saturday morning, that I would build it. I had no vote and no objections were allowed. I would build it.

The first idea was to transmit AFSK tones through the local 147.06/.66 repeater. It used subaudible tone control, and few people used it. This method was tried, and it worked with some success, but different tone frequencies and levels caused problems in copying. What was needed were standard tones from the repeater.

Looking through the Flesher catalog, the answer stood out like a BY prefix on twenty. I could demodulate the incoming RTTY audio using the Flesher DM-170 and use the loop-keyer output transistor to key the FS-1 Audio Frequency Shift Keyer to feed audio to the mike input of the repeater transmitter. As an added bonus, I could use the autostart circuitry (on the DM-170) to operate the transmitter PTT control, clean and simple. Flesher even has a nice little power supply to operate both boards—Model TTP-12. All these goodies cost less than $100.00. The boards arrived in 4 days!

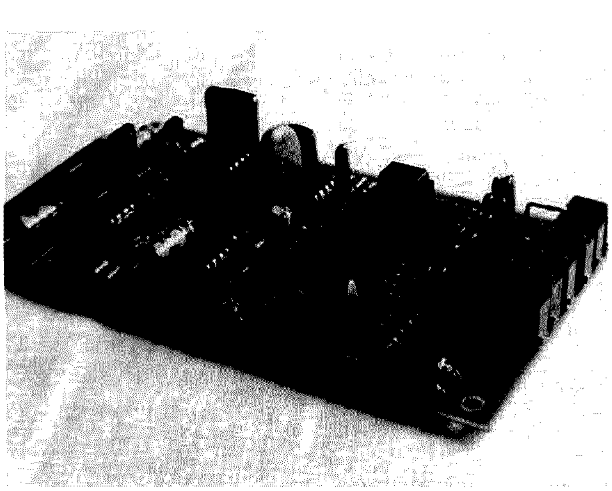

Photo A. Modified DM-170 showing use of 6 trimpots in place of 12 fixed resistors.

The FS-1 and power supply were constructed by K5OG, and I assembled the DM-170. Total construction time was about four hours and the boards worked the first time. The only problem was that hand-picking resistors to tune the DM-170 was slow and somewhat inaccurate. The DM-170 copied 20-meter RTTY perfectly, but I was bothered by the resistors. I assumed Flesher had used the resistors as a cost-cutting technique. However, my RTTY converter had to be perfect. I cut the 12 fixed resistors from the board (R14, 15, 18, 19, 22, 23, 26, 27, 30, 31, 34, 35) and superglued six Weston 850W 2k trimpots in place of them (see Photo A and Fig. 2).

Flesher's design used two resistors in parallel connected to the "−" terminals, pin 6 or 2 of the op amps serving as filters. The tune-up is similar to their method. When the pots are glued to the board, only one lead is connected to the ground for each pot and the wiper arm of the pot is soldered to the correct terminal as you tune that stage. (Read their instructions and use their method of tuning, and tuning the pots will be very straightforward.) I tuned the board with the pots in 15 minutes. It takes an hour with the hand-selected resistors.

I used an H-P audio oscillator driving a frequency counter as my frequency standard. It is important to keep the audio level to the DM-170 as low as possible to get accurate tuning. I faced the problem of having too much audio to the DM-170 when I had correct audio to the counter. I solved this by using a BNC T-connector on the oscillator, feeding directly to the counter and using a 10-to-1 scope probe as an attenuator to feed the DM-170. I now could lower the audio

oscillator to the correct level without losing the counter.

The DM-170 has an "improved mark hold" option which is the installation of an additional diode. I suggest this be installed to force the board to mark any time the audio is lost. This feature is very nice when the DM-170 is keying the FS-1. As soon as the repeater comes on the air, it transmits a steady mark. This mark is our local reference and is a convenient 2125 mark for tuning filters.

While building the board, install a wire from Q5 base to pin 2 of the edge connector to key RY1.

The Motorola repeater I was using has a 5-volt dc to ground to key the PTT. The autostart transistor (Q5) collector was used to take this voltage to ground. Without making any timing changes or adding the threshold control as suggested by Flesher, the repeater would key up after receiving six seconds of steady mark. The repeater would drop out 15 seconds after the input audio to the DM-170 was removed. These times proved popular with the local RTTY users so they were left unchanged. The threshold control was never added. The six-second delay prevents kerchunking the repeater, and the sharpness of the filter and time required prevents someone from whistling the machine up. The 15-second off delay gives a reasonable time to look at filter tuning or to zero your AFSK unit to the repeater mark. I found it possible to rough-tune a filter and AFSK unit enough to get on the air by zero beating the mark and space audio from another QSO.

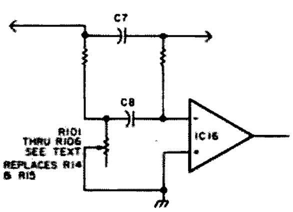

Fig. 2. Pot connection to DM-170.

The nice thing about using a demod and AFSK at the repeater is that everyone hears the same mark and space. Gone are the problems of who has the correct frequency. The only operating problem using this arrangement is the need to use a 170-cycle shift for the CW ID requirement. The mark/hold circuit will not repeat the narrower shifts used for some CW IDs. When the 170-Hz shift is used, the repeater will transmit the ID in CW as it is received. I don't consider the small bit of garbage from the CW on my screen a problem.

After operating the machine a few weeks, several operators wanted the audio for voice communication back on the machine so they could talk about RTTY problems without changing frequencies. A small 12-volt relay was installed to switch the input audio between the receiver audio and the FS-1 unit. A 2N2222 transistor controlled by the base voltage of Q5 through a 330-Ohm resistor was used to ground the coil of the relay. The relay closes in the RTTY mode.

When the repeater was in the standby mode, the subaudible tone would key it in the voice mode. Or, when 6 seconds of mark were received, the relay would close and the repeater would come up in the RTTY mode and transmit a steady mark until it received a RTTY signal, or it would stay up for 15 seconds and drop.

The repeater IDer is connected to ID when the transmitter is activated, regardless of mode. In the voice mode, operation is normal as required by FCC rules and can be heard in the background of voice communication. In the RTTY mode, the operation

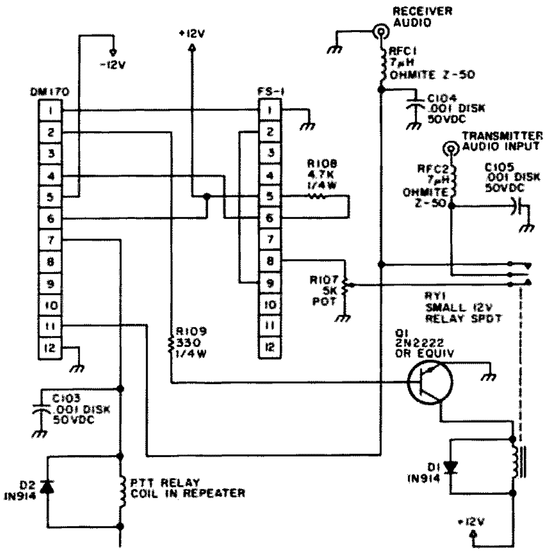

Fig. 1. Interface connections for RTTY repeater modifications.

of the IDer is the same as voice, except the RTTY filters at the receiving RTTY station do not acknowledge the 700-Hz repeater ID frequency. So far, no one has complained of garbled copy due to the repeater ID unit. The repeater can properly ID itself and it will repeat the CW FSK IDs from the user RTTY station. Using this relay arrangement gives RTTY priority over voice and keeps voice communication in the input frequency from garbling RTTY copy.

All three boards were mounted in a 3-inch chassis which was mounted inside the repeater cabinet. With a cover in place and proper line filtering and audio filtering, there were no rf problems. It is important to use proper filtering as rf will keep the autostart in the on mode and keep the transmitter up. Connection of the FS-1 board is straightforward. Connect the proper output to match your repeater input level, adjusting R107 as needed to match the level of the RTTY tones to the level of the receiver voice audio, using a deviation meter monitoring the transmitter output.

Using the direct keyboard connection drawing shown in the FS-1 instructions, connect the junction of pin 6 and the 4.7k resistor to the collector of Q6 on the DM-170 (pin 4, loop keyer). The FS-1 will now track the DM-170 mark for mark and space for space, including CW IDs.

The TTP-12 power supply provides ±12 volts at 0.2 Amps and maintains regulation through a wide range of input voltages. The specifications for the DM-170 call for ±15 volts, but the board will operate fine with the 12 volts supplied from the TTP-12—just use the supply when you tune the filters. Install a power switch in the ac line, because the DM-170 will key the transmitter for 15 seconds at power on. When you bring your repeater up from a cold start, wait the required warm-up time if you are using a tube final and then turn on the RTTY boards.

It's not bad for a hundred bucks and a few hours of work. ■

A Patch for the TS-120S

—add phone patch compatibility

When I bought a Kenwood TS-120S and sold my Drake TR-4C, it cost my station phone-patch capability. There's just no graceful way of mating the existing patch with the Kenwood's input and output accesses. That brought on the challenge of second-guessing the Japanese engineers. Sometimes that's easy; often it's not. There seems to be an unwritten law (or is it written?) that all equipment must be designed to make customer modifications difficult.

A bit of study of the schematic wiring diagram for the TS-120S revealed an unused terminal (#7) on the remote connector. More study revealed that audio signal and send-receive functions were available at the remote connector. Ah, now if one had microphone input also available... Could it be just a matter of piping a wee bit of audio to the mic input jack from that unused (#7) terminal? It looked feasible on paper, but it pays never to leap too precipitately to conclusions. So the next step involved a bit of exploration of the innards.

If you've never uncovered your TS-120S, a word or two of advice might be of worth. Take the top cover off first, taking care not to disturb the four screws that hold the internal speaker in place. It's not necessary to remove the top totally; just loosen it and slightly move it from place. Now you can flip the set over on its top side without endangering the three top controls and without having to worry about the lead to the speaker.

With the top loose, the bottom comes off readily. Once it's off, take a look at the back side of the mic connector. One of the four terminals has a single white wire going to it. That's the one you're interested in! And it's the one most easily reached! No doubt the Japanese engineer responsible for this grievous faux pas has been compelled to commit hara-kiri.

But how about the other end? Not to worry! There's a plate mounting a number of jacks, the remote connector among them. This plate comes out with the removal of five screws. Once out, terminal #7 is most easily reached. Ah, breathe a prayer for the soul of the poor engineer!

Now, all that remains is to find a single-wire shielded conductor small enough to snake along the edge of the chassis. There are holes through the compartment shielding to accommodate a small and flexible cable. I suggest you ground the shield of this wire only at one end (I used the terminal #7 end) to avoid ground loops.

The remote connector now provides the following services: ground and #1—audio output, 8 Ohms; ground and #3—send-receive control; ground and #7—audio input, high impedance.

You might take a hint from the wiring diagram and put a 100-Ohm resistor in series with that audio output. This will both reduce the signal level (most likely too high for phone lines) and also protect the output transistors from any non-kosher load a phone patch may offer.

The introduction of the capacitance of the short cable across the mic circuit has made no detectable difference in the quality of the voice signal from my TS-120S.■

Successful Ham Classes

—a guide for club organizers

In 3 years, I organized 11 ham code and theory classes, with the following results:

- 70 Novices
- 40 Generals
- 5 Advanced
- 2 Extras

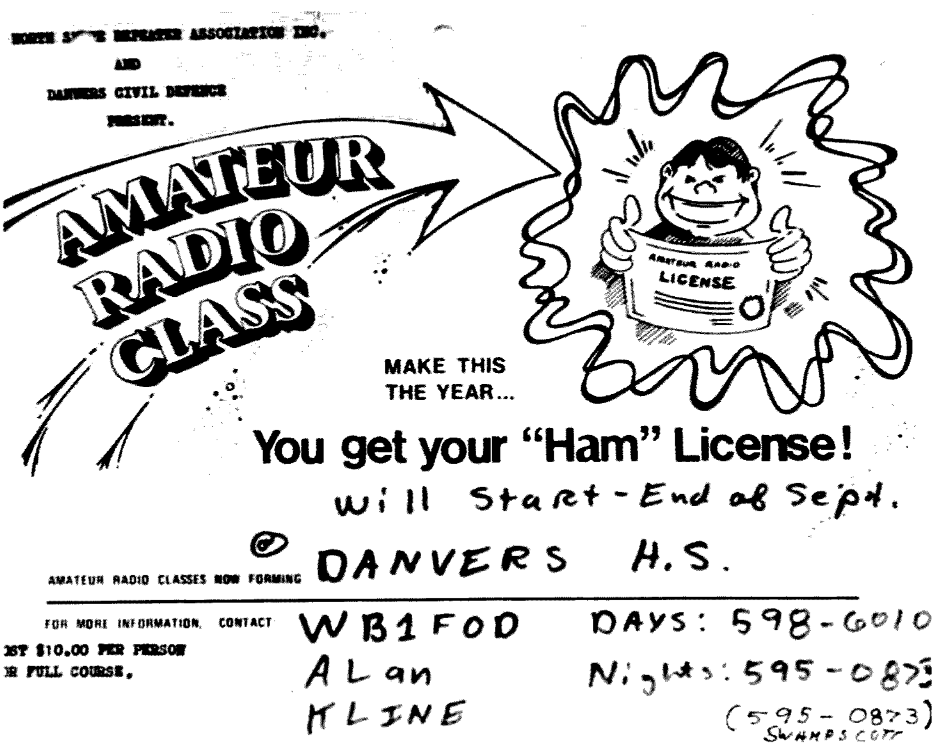
—with two more classes starting the first of the year in two different locations. If I can do it, so can you; here's how I did it, with help from my club members.

It all started when I joined the local repeater club and became friends with the club's secretary. Every morning for months we would meet at the local post office and he would fill me in on the club's history and current events. The ARRL had been pushing all clubs to sponsor classes to beef up the number of U.S. hams before the WARC conference. As the club had not fulfilled this request, he felt they should start some kind of educational program. I volunteered for the job.

Before I was going to organize *any* program, I had to know if there was a need. As there were classes in a town only 10 miles away, I wanted to be sure we would be successful in our attempts. It was discussed at length at my work QTH and decided that a marketing survey could be conducted to establish the community's ham radio educational needs. A test market of a 20-mile radius within our repeater's coverage would be a good parameter. I set out to do a direct-mail market survey.

As the survey needed to go to unlicensed but potential hams, I remembered having once been an associate member of the ARRL. Associate members are the unlicensed league members who get *QST* every month. For various reasons, this group joins the League, and the results from this mailing would show that this group had need for a class to help many of them get their tickets.

In requesting a list of the



This is the standard poster I use. It is from the League, but I like to add information to it.

League's associate members, the League told me any ARRL affiliated club could request a computer printout of the League's mailing list by zip code. The list is conveniently printed on pressure-sensitive labels.

Upon receiving the list, I immediately had it duplicated. Certain brands of commercial copying machines have this capability. I was glad I made three copies, because later I would find out that the League will only supply the list once a year. A quick scan of the labels produced the mailing list of associates I was to use. The rest of the list was used to solicit membership and to announce the General and Advanced classes.

Response

I printed an announcement of the possibility of having Novice and General classes and mailed one out to each of the fifty potential hams on the League's associate member list. There was instant response. All of the 25 calls I got were logged in a notebook with addresses and the callers' stories. By their stories, I mean that they all had various reasons for joining the League and for not being licensed.

The first caller claimed to be able to copy code at 20 wpm. He was in his early sixties and nearing retirement age, having learned his CW in the army in WWII, and he had never forgotten it. A Drake TR-4 was used to copy code for many years, but he never had the help he seemed to need to get a ticket. The second caller was a Vietnam veteran who also had learned the code in the service. Both of these calls were typical of the many I would receive.

Three of the responses came from adults with various handicaps. They had long-time interests in communications, but needed help to get on the air. To help them with their individual problems, I joined the Handi-Ham System at the Courage Center in Minnesota. Their program is a United Fund-sponsored agency that helps the handicapped not only get their tickets, but loans them equipment. Involvement in the Handi-Ham System has led me and my instructors into some very rewarding personal experiences.

A Committee Is Formed

Based on the calls I got, I knew there was need for a class of some kind. I announced that I was going to organize a class and asked the repeater club membership for help. We formed the club's first educational committee.

Those involved included a high-school guidance counselor with much teaching experience, a professional musician and teacher, a state safety inspector, and an electronics technician. (I am a ladder and scaffolding salesman.) After talking with them, I decided they all had the ability to explain ham radio and communications in layman's terms. In selecting teachers, you must let only the active hams do most of the teaching. It didn't take long to realize that my lack of CW experience and primary interest in VHF/UHF was of little help to aspiring Novices. I decided to stick to the organizational end of the program.

At this point, I contacted the Club and Training Department at the League and, for $1.50, they sent me their instructor's package. It included many items of interest. The first is a 10-12-week lesson plan for teaching a Novice class. It is written to go along with the ARRL's *Tune in the World* textbook and code tape. In later classes, we only used this as a guide for the teachers and let the students choose their own books.

Don Robson, 12 Boulder Way, Swampscott MA 09107. Don is blind and confined to a wheelchair. One of our first students, he worked hard for 18 months before getting his ticket. The repeater club gave him a standing ovation the night he came to announce his call.

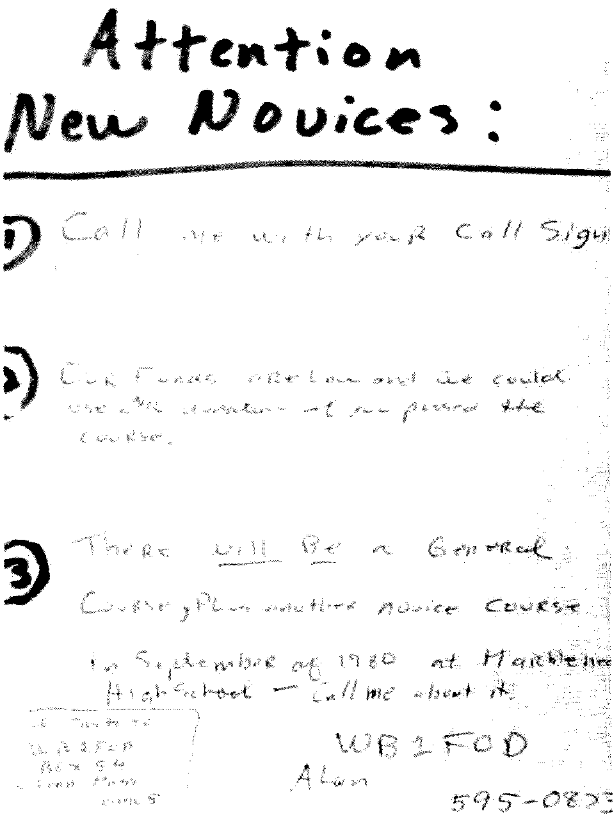
The second booklet was a workbook with problems and duplications of the League's 35mm Novice slide program. We invested in two sets of these slides so our instructors could reinforce hard-to-explain concepts. The third and most useful booklet is entitled *How to Start a Course in Amateur Radio*. After carefully reading all this material, I knew we were heading in the right direction.

For our first class, we decided to use the *Tune in the World* series plus the *73 Magazine* code tapes.

Rooms

In scouting out potential classroom sites, I had to remember the need for wheelchair access ramps. The room also would need to have a movie screen, blackboards, and ac outlets, and, most importantly, be in a good location for the students to drive to. In most communities there is usually a building that meets these requirements. Our first site was the local high school in my hometown. The school was open four nights a week for the town's adult education program and still had many large vacant rooms.

Since the students do not all pass the code at the same time, it is necessary to separate some students from the others. As the code exam is given, the students who pass it earlier than the rest will get their written exams back from Gettysburg before the slower students. If you have a second room, you can split the class into two groups each night. One group will



This is a follow-up mailer for a class we didn't have any money for. At least half the class responded by sending money.

always be in the second room taking one of the two exams. Because the FCC doesn't let instructors have bulk exams anymore, the Novice instructor is always burdened with the extra work of sending exams back to the FCC at staggered times.

I contacted the director of continuing education at the school I selected and arranged for three rooms. One was a large sewing room with big desks that served as Novice classroom number one. It was big enough to seat 25 students, three wheelchairs, and also large enough for our demonstrations. The second classroom was across the hall and was used as the extra exam room.

The third room was the high school's electronics lab. We chose to teach a small General class in there. Besides having VTVMs and scopes, there was a general coverage receiver. Lots of other electronic equipment there made it easier to teach prospective Generals. Most regional vocational technical high schools and junior colleges have similar labs and might be willing to let you use them.

Media	Calls	Percent of Total Calls
Newspaper ads	90	45
Heathkit posters	60	30
ARRL lists	20	10
Ham stores	20	10
Word of mouth	10	5
Totals	200	100

Table 1.

Taxpayers like to see and hear about the school being used as much as possible.

At this point, I made my first mistake: I offered to pay for the rooms. We had to charge $25 per student to cover our initial costs. For that, they received the *Tune in the World* package and a guarantee of a Novice license! When the time came to make the next year's arrangements for rooms, I had learned that most school departments are more than willing to let any civic group use their facilities.

For our second year's program, the town of Danvers, Massachusetts, civil defense radio unit was the repeater's cosponsor. The superintendent of schools and the school committee were glad to give us the needed four rooms at no charge. We met as part of the adult education program on Thursday nights. Both the school and the CD unit helped the club advertise the classes.

During the second half of the school year, we had planned only to teach the follow-up General class and a small Advanced class at the Danvers site. But there were so many calls for a Novice class, we quickly organized two new Novice classes in both Danvers and Swampscott.

Other Sites

Other room ideas I checked out and will probably use at later dates were the local hospital where our repeater is housed, the Boys Clubs and Girls Clubs, the Red Cross headquarters, a private nursing home, and both state colleges. Whereever you find a suitable room, try to contract for it for no fee. There will be plenty of ways to show the landlord your club's appreciation. Also, don't be surprised if the landlord, i.e., the school department, asks your club to sign a contract for the rooms. They must establish responsibility for not only the cleanup of the premises but also the liability in case of an accident.

Our current class is part of the very successful adult education program of the town of Marblehead, Massachusetts. It is a coordinated effort between the repeater club, the town, and the high school's industrial arts department. One class meets after school and the others on Thursday nights. Funds collected from the evening program will be used to donate station equipment to the school's new station.

Our other class is at the Lenox Hill Nursing Home in Lynn, Massachusetts. It is a private institution with many handicapped young people. The director was a radio operator during the Korean War who immediately saw the value of adding ham radio as a weekly activity. We will set up a station there (donated by Handi-Hams) and have a regular schedule of operators drop in during the week to use it. As interest in ham radio grows, we will show the recently produced Dave Bell film on ham radio to the patients. I'm sure we will have a small group of people interested enough to start teaching code and theory.

Our final teaching effort for this year will be a similar wintertime project at the Greater Lynn Boys Club. As an urban club, its membership swells in the winter months, and not all young people enjoy sports. These 5th, 6th, and 7th graders could turn out to be the future electronic technicians this country needs.

Finding Students

Armed with the results of the original test mailing, it was time to find more potential students. In advertising for our first class, an-

nouncements were sent out by mail to all the high schools, junior high schools, vocational schools, colleges, community centers, scout groups, and other ham clubs. A news release was also sent to all the newspapers, radio stations, and local magazines. And finally, posters were put up in the electronics stores, Heathkit® store, both ham stores, and local surplus emporiums. When having a class for the first time, you can never advertise too much. After logging the answers to the question of how the students heard about your class, you can decide which advertising media worked best.

Table 1 shows the results over a six-month period of sending out the announcements of the course and logging all the return calls. Using these statistics, much less advertising effort was required for our second and third classes. A small poster at the Heathkit store and Tufts Radio in Medford, Massachusetts, generated about 50% of the calls. The rest came from a small news item that reappeared weekly for four weeks in the local newspaper.

Careful selection of which newspaper to use was also a factor. In the towns we teach in, the residents all seem to read the smaller weekly papers that have a weekly events column. The one I chose was a weekly tabloid with more real estate ads and community news items than daily news.

Most students, when queried, said they saw or heard about the classes from more than one source. Many not only read about it in the newspapers, but heard about it from a repeater member or on the CB band. On a few occasions, I would answer questions about the class or ham radio in general on the CB band.

Once you've gone this far and generated all this interest, be prepared for the phone to start ringing. Find a retired or handicapped ham who is home a lot to take and log all the calls. He must be prepared to explain all facets of ham radio and mail out the ARRL's supplied material. Many people will call and not attend the next class, so it is important that they stay on your mailing list.

When writing announcements for the media, keep them as formal as possible. They should be typed on the club's letterheads and be neat. You want to convey that the organization running the classes is a professional one. When writing anything for the students, I wanted to project that ham radio is a relaxing, informal hobby. To help create this informal atmosphere, I always hand-wrote the announcements for the students. We always stress that anyone who puts in the effort and learns the required code will get the help they need to get their ticket—no matter how long it takes.

Many students who don't pass the course the first time will be hesitant to come again unless you have this relaxed atmosphere. Informality helps break down many barriers between the teachers and the students.

Teamwork

When it is possible, have three instructors for each Novice class. Two will alternate teaching the theory and the other will teach code and give exams. If any one of the three is absent, and that will happen, there will always be a back-up instructor who knows the students and the lesson plan. You can delegate one of them to handle all the paperwork. In our program, I do all the paperwork and advertising and leave the instructors to do what they do best.

This is a typical announcement that was mailed to potential students. It was changed to offer a Novice class on short notice.

General and Advanced classes only require one teacher who is an active ham. By active, I mean one who has worked all modes and all bands. It is less important that you have a backup instructor for these classes, as the General students can always sit in on the Novice classes. The unlicensed Novices will have fun that night because they can spend the night asking the Generals questions about the hobby.

If you have only one Novice instructor, keep the class size as small as possible. One teacher can only handle about ten struggling Novices. We had no intentions of offering a Novice class during one session, but when 22 students showed up, a volunteer was called on the repeater and he gave it a good try. His passing rate was much lower than our other classes.

Opening Night

The most important meeting is always the first. For the first course we ran, on the first night, the four instructors all talked about some aspect of ham radio that they were into, public service, DX, RTTY, ATV, and CW, but this didn't work. Murphy's Law of boasting took over and each ham tried to out-talk the other. Too much material was covered. We didn't remember that the students were there because they already knew something about ham radio.

The correct first-night procedure should be to show one of the League's films. They cover all aspects of the hobby in 30 to 45 minutes. After showing the film, you can go right into the first night's lesson.

One of the weekly handouts.

Other first-night chores include introducing the teachers and having all the students introduce themselves. It is also helpful to have them tell why they came to the class and explain their communications experience.

Keeping the Interest

In most classes, the dropout rate was as high as 50%, and they all dropped out within the first few weeks of code lessons. To keep student attention during this period, we tried to provide some sort of a handout at each class. They were either a small electronic part, catalog from an electronics company, or a printed sheet on antennas or circuits. We also brought in a different piece of ham gear each week to discuss. We were trying to string along the slow learners so they wouldn't get discouraged. Many of these methods worked.

Ham radio, like all hobbies, has its magazines, stores, and clubs. To help out aspiring Novices, each class has its own booklet. The booklet contains a short message from the sponsors, dates of meetings, teachers' names and calls, local repeaters to listen to on their scanners, W1AW code schedules, recommended magazines, parts stores, study guides, code tape sources, club meeting sites and times, and a ten-point check list on buying their first rig.

Since our repeater is located on the North Shore of Massachusetts, the booklet is entitled *An Introduction to Ham Radio on the North Shore*. With each new class, we add additional information we feel is needed, as most of us forget a lot of these facts ourselves. This booklet is also good as a ham radio public relations tool.

At each class after that you can pass out the other sheets and catalogs previously mentioned. Other good handouts we used were reprints of Novice articles, flea-market flyers, and old issues of ham radio magazines that came from the club members. The local Heathkit manager was not only a great help in supplying books, but also supplied catalogs, space for our posters, and a small kit for no charge. The printed circuit board, after having been assembled, was brought into a Heathkit store for checking. If it were properly built, it acted like an oscillator. It was a good gimmick for all involved.

Final Handout

The final handout should be an SASE or postcard for the students to mail back with their callsign. I usually put it this way: We need to know if our teaching efforts were successful—please let us know your callsign, and, if you didn't pass the exam, let us know if you want to try again. All students are so proud and so grateful for your help, that very few don't return the cards. Sometimes they are like QSL cards; a few will show up months later from other states because the students have moved.

Follow-Up

At this point, you might think that you've done your part. Not so! Most new hams will need some encouragement to get through that first CW contact. The club should start a slow-speed CW net that meets at least once a week. This is a good way to get other club members active in helping out the educational committee. Also, anyone who doesn't get a license should stay on your mailing list for future classes. We heard many personal reasons for dropping out of classes, but in a lot of cases they would sign up for another class at a more convenient time.

Registration Forms

In making up registration forms for both the repeater club and our classes, we ask for all the pertinent information such as name, nickname, address, town, summer address, zip codes, phone number, mailing address, if different, home and work phone numbers, bands active on, mobile or portable capabilities, and, finally, these important questions. First, how did you hear about the class? This will give you ideas on which advertising works best.

Second, what is your job or profession? This question is usually overlooked by clubs and here is why it's important. In the classroom, if the teacher knows everyone's backgound and jobs, he can draw on those talents in making analogies. This shows your interest in the students and if the club's board of directors has access to a list of what each member does for a living, they can draw from this group for meeting programs.

Clubs and classes are always in need of new speakers on both technical subjects and human interest stories. One good example of this was a husband who called to sign his wife up for a Novice class. In the conversation I found out that he was an Advanced class ham who was the new Belden cable salesman for the area. He was glad to talk to both the club and classes!

Deadlines

When printing up your class registration forms, always make the deadline for enrollment at least one week before your first night. This allows you to know exactly how much material you will need. It was a big surprise, at one first meeting, to have 20 more people show up for a Novice class than the 30 who had sent in checks. If you have a small class and decide to supply textbooks for them, it takes at least two weeks to procure them.

Our first attempt included the ARRL's *Tune in the World* which required careful guess work on the projected number of attendees. In later classes, we purchased ample supplies of the League's or Ameco's question-and-answer-style books.

Money

Having a total of 11 classes over three years with fees ranging to $25 per family member, we generated plenty of money to purchase all the supplies, code tapes, slide programs, books, and teachers' guides. Since I was the chairman of our educational committee, I usually decided what else the money was spent on.

As a club, we recently gave the town and high school libraries in three communities the ARRL's complete set of current publications. The League will sell any affiliated club this package for only $55. All six librarians were gracious enough to accept the donations at our annual meeting for the installation of new officers. A picture was taken and a small article appeared in the local paper about the books and our new officers. It was a good ham radio PR move.

Even if your club decides to underwrite the costs of the class, it's still important to charge for the class. I've argued this point many times over the air, but I am convinced the $10 or so you charge makes the student feel he has made a commitment. No student has ever questioned our fees, and many have made other donations. When asked what happened to the money, I always explained the Handi-Ham System, because all the extra funds were used to put the handicapped on the air.

Thank You

By donating books and new ham gear to the towns and school systems that provided rooms for our use, we had thanked them in our own way. In some other nearby communities, the ham radio instructors are paid as paid regular teachers in the evening school. None of my instructors gets any money out of our projects, but in my own way I showed them my appreciation.

After two years of teaching one night a week, my ten instructors had spent a lot of time teaching ham radio. I know that they would have been happy enough with the students' individual thank-yous, but that was not enough. My wife and I had the instructors over to our home, with their wives, for a dinner party. I wanted them and especially their wives to know how special this group was to me. I got a lot of thank-yous from the students and club members, but it was this group who actually got the teaching done.

After you organize your first class, no matter how large or small, and the first happy Novice calls up to say, "I just got my callsign—KA1FCC," you'll know why we don't want to stop organizing them. If you think there aren't any people interested in ham radio classes for you to teach, then start by generating interest. I don't know how many classes we will help run over the next few years, but with the help of my fellow club members, the Courage Center, an understanding boss, and especially my wife, I look forward to many more happy Novices and Generals calling up to say "thank you."■

How FCC Rules Are Made

—a labyrinthine tale

Carey P. Busbin WD4DAZ
541 Broadway
Birmingham AL 35209

I think it appropriate to begin this discussion with a brief history of radio transmission and subsequent regulation. Federal regulation of interstate electrical communication can be traced to the *Post Roads Act of 1866*, which authorized the Postmaster General to fix rates annually for government tele-

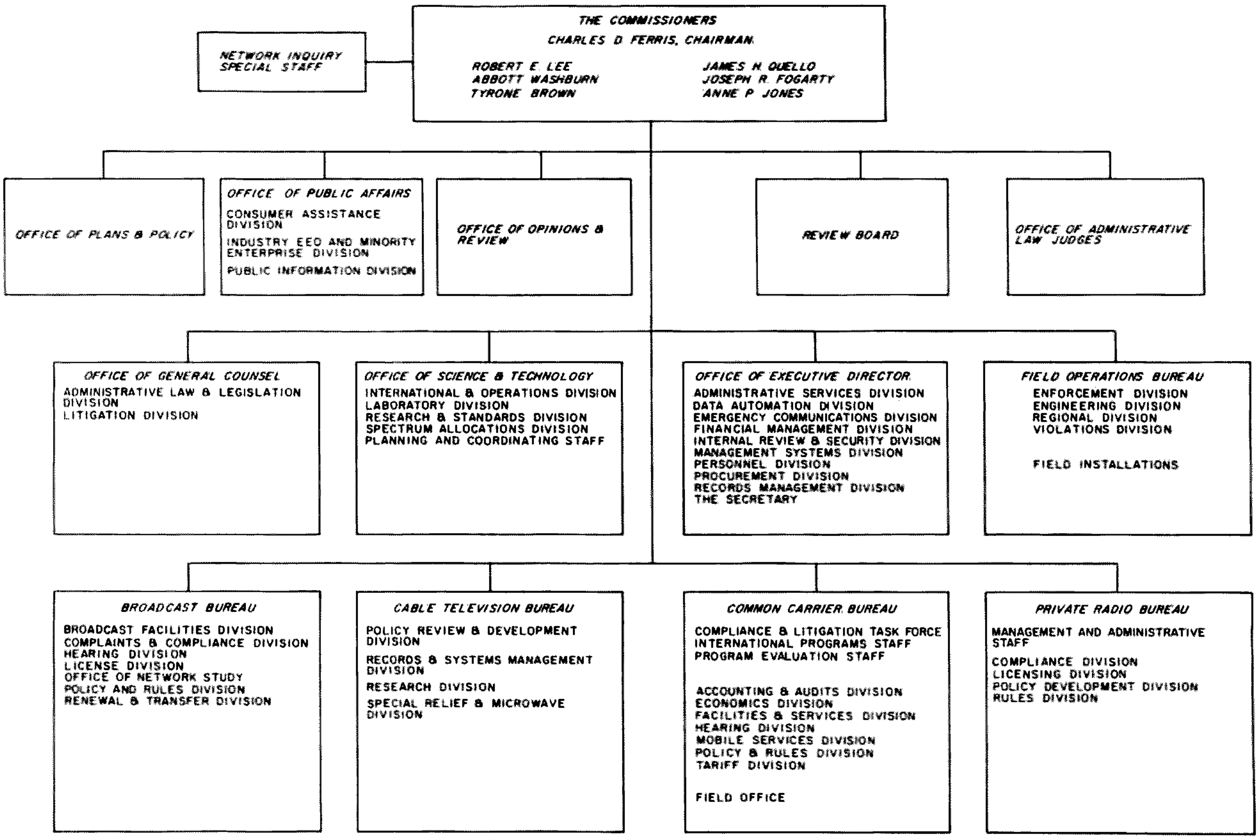

Fig. 1. FCC organization.

grams. This was followed by the *Interstate Commerce Act of 1887*, which granted the Interstate Commerce Commission (ICC) authority to require interconnection of telegraph systems to expand coverage across the country. Then, the *Vann-Elkins Act of 1910* directed the ICC to develop uniform accounting practices for these telegraph systems. This statute, in effect, extended provisions of existing law to cover certain wireless telegraphy. By 1910, wireless radio transmissions had proven worthwhile aboard ships, and the *Wireless Ship Act of 1910* required radio installation on large seagoing passenger vessels.

Two years later, the United States participated in the International Radio Telegraph Conference. Conference findings were the basis for the *Radio Act of 1912*. This Act regulated emissions, distress calls, set aside frequencies for government use, and mandated licensing. Licensing began later that year.

World War I ensued, and the Federal Government exercised control of radio, telephone, and telegraph as a precautionary measure. After the war, a tremendous growth in broadcast radio occurred. Broadcast radio had been unregulated by the legislation of 1912, which prompted President Coolidge to request of Congress the authority to control this growth. Congress responded with the *Dill-White Radio Act of 1927*. This Act established a five-member Federal Radio Commission under the Secretary of Commerce, with regulatory powers over radio.

Broadcast radio continued to prosper, and in 1934 Franklin D. Roosevelt asked Congress to approve the establishment of an independent commission to regulate radio transmissions. Congress responded by passing the *Communications Act of 1934*. This Act contained six major sections, or titles, and created the seven-member Federal Communications Commission (FCC) as we know it today.

There were extensive revisions to this Act, both in 1952 and during the period of 1960 to 1962. More recently, the *Communications Satellite Act of 1962* gave the FCC new responsibilities in the areas of space communications. Thus, over a period of time, Congress delegated authority to the FCC to govern radio; therefore, the Commission may develop regulations as they feel necessary to carry out these responsibilities.

Organization of the FCC

The seven commissioners are appointed for seven years by the President with the approval of the Senate. The Commission's chairman is selected by and serves at the pleasure of the President. The commissioners function as a unit, supervising all FCC activities. This is accomplished by delegating responsibilities to boards and staff units. Fig. 1 shows a current organizational chart for the FCC (amateur radio is within the Private Radio Bureau).

Rule Making

In order for the FCC to regulate radio transmissions as directed, the FCC must develop rules and regulations. Fig. 2 shows the pathway which a new Rule Making may follow. Using Fig. 2, let's begin at step 1 and follow a request for either a new rule or a rule change through the entire process.

Step 1. *Initiation of Action*. Any individual represented by one of the five groups may initiate a Rule Making.

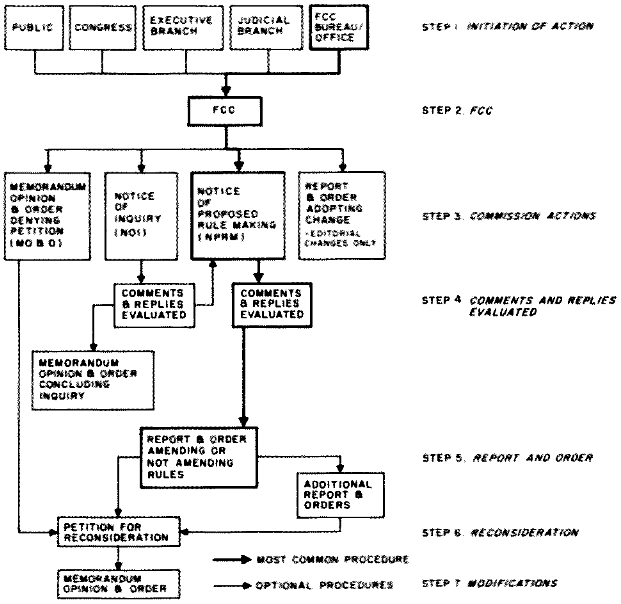

Fig. 2. FCC Rule Making diagram (from FCC Communicator, *September, 1975).*

Step 2. *FCC*. When a petition for Rule Making is received, it is sent to the appropriate Bureau for evaluation (the Private Radio Bureau for amateur regulations). If the Bureau decides a petition is meritorious, it will request that the Dockets Section assign a Rule Making (RM) number. The Bureau may then request one of four actions by the Commission as shown. A free weekly summary of Commission actions, *FCC Actions Alert*, is available from the FCC; the address for obtaining this publication will be found at the end of the "Publications" section.

Step 3. *Commission Actions*. If the Rule Making would require major changes in the rules, the Commission will issue either a Notice of Inquiry (NOI) or an Notice of Proposed Rule Making (NPRM). When either an NOI or an NPRM is requested, such a request will appear both in the *Federal Register* and the *FCC Actions Alert*. The NOI is basically to see if there is enough public interest to merit further consideration. The NPRM is an official announcement that a new rule is being considered. If the Commission feels that the proposal did not merit further consideration, they would issue a Memorandum Opinion and Order (MO), which would stop the action. The NOI usually leads to either an NPRM or an MO. An NPRM usually leads to a Report and Order (RO) or an MO. The RO either issues a new rule or amends and confirms an existing rule.

Step 4. *Comments and Replies Evaluated*. When an NOI or an NPRM is issued, the FCC solicits public comment. Replies to public comments are also solicited. Any comment or reply should reference the Docket Number.

Step 5. *Report and Order*. An RO is issued to institute a new rule, amend an existing rule, or confirm the current rule.

Step 6. *Reconsideration*. Petitions for reconsidera-

tion must be filed within 30 days.

Step 7. *Modifications*. A review of a petition for reconsideration may merit a change in the initial decision. The Commission may issue an MO to amend the initial decision.

Commenting

If you intend to file comments, the following subjects should be addressed. First, state your experience, expertise, and any insights which make your judgments accurate and worthwhile. Second, any facts, comments, or opinions should be clearly stated in easily understood fashion. Third, your comments should reach the Commission on or before the comment deadline. Moreover, if you intend to submit comments as a formal filing, you must submit an original and five copies. Comments should be submitted to: Secretary, Federal Communications Commission, 1919 M Street NW, Washington DC 20554. Be sure to note the Docket Number on the comments.

To help in filing comments, the next section will outline various materials available on the subject, and where they may be obtained. These publications will add clarity to FCC policies and procedures.

Publications

A) *Federal Register*, a daily publication from the U.S. Government which covers both proposed and official changes in regulations prepared by government agencies. The FCC is just one of hundreds of agencies and commissions which publish regulations in the *Federal Register*. A subscription may be obtained for $50 yearly from the Superintendent of Documents. The *Federal Register* is usually available at libraries in most areas.

B) *FCC Actions Alert*, a weekly bulletin published by the FCC containing Commission actions. The *FCC Actions Alert* is available without charge from the FCC.

C) *FCC Reports* contain complete texts of FCC reports and actions and is available for a fee from the Superintendent of Documents.

D) *FCC Rules and Regulations* is a looseleaf subscription service which continually updates the FCC regulations covered by that particular subscription. In order to cover all FCC Rules and Regulations, several separate subscriptions would be required. Information concerning which parts each subscription covers and how they may be ordered will be found in the U.S. Government Printing Office pamphlet *SB-281*, as described below.

E) *Federal Communications Commission Publication SB-281* is a subject bibliography available without charge from the Superintendent of Documents and lists all publications available from the U.S. Printing Office concerning the FCC.

F) *FCC Information Bulletins* are available without charge upon request from the FCC. Each bulletin covers a specific area of the FCC's responsibilities or a topic of interest to radio enthusiasts.

Federal Register, FCC Reports, FCC Rules and Regulations, and subject bibliography *SB-281* are available from: Superintendent of Documents, U.S. Government Printing Office, Washington DC 20402.

FCC Actions Alert and *FCC Information Bulletins* are available from: Federal Communications Commission, 1919 M Street NW, Washington DC 20554.

Summary

Amateur radio clubs should be apprised of proposed changes in FCC regulations which affect amateur radio. Too often over the last few years, we learned that we were the subject of substantial changes without sufficient prior notice. Because of printing and mailing lead times necessary with publishing magazines, it is very possible that the FCC comment period is long over by the time you receive the current issue containing the notice. This can be avoided by having the club or a responsible individual placed on the *FCC Actions Alert* mailing list (see "Publications"). If a Rule Making concerning amateur radio is received, then the membership can be notified. In addition, the FCC maintains two phone numbers, one for general information from the Public Information Officer, (202)-632-7260, and the second, a recorded message concerning weekly actions, at (202)-632-0002 (neither is toll-free).

As you know, the trend regarding frequencies has been "use them or lose them"; the same is true of Rule Makings. Failure by the FCC to receive a number of comments on proposals means to the regulator that there is little or no interest in the subject; therefore, they should proceed with their proposals. Many times this just isn't true. Therefore, I suggest that you as an individual or club member monitor FCC Rule Makings, perhaps even suggesting changes in amateur regulations which you feel merit consideration. Your very participation will help ensure the place of amateur radio in the future. ■

REVIEW

from page 32

the manual, "The quality of copy is directly proportional to the quality of the signal being received as well as the quality of the CW being received. If you are trying to copy a guy with a sloppy fist, then you'd better expect sloppy copy. If, on the other hand, the CW is being sent by a keyer or a keyboard, the copy will probably be perfect." Amen. If you intend to use the ROM-116 for serious CW reception, get a good CW filter and talk only to people who can send well! Whatever conclusions you draw about machine-read CW, the transmit portion of the ROM-116 is faultless. It is easy to use, sends perfectly, and even allows you to start typing a reply while receiving a message.

By necessity, this is only a brief overview of the capabilities of the ROM-116; it has many intriguing features that are not mentioned in this review. How did it perform in the real world? Superbly. It is at the top of its class. With equipment like this on the market, the old stalwarts are going to have to brace themselves for an influx of enthusiastic operators using computer-based RTTY gear. Few people who listen in on the RTTY segments of the band will be surprised if RTTY operation begins to spread out and take more spectrum. Things are already pretty crowded! A device like the ROM-116 will attract a lot of people to RTTY who would never have considered it before —people like me!

There is one big if that deserves mentioning. Microcomputers, to varying degrees, can emit a lot of hash into the rf spectrum. If your computer is unshielded (as is the TRS-80), you may or may not hear a great deal of noise in your receiver, all generated by the computer. In the *73* shack, using unshielded interconnecting cables and making absolutely no effort to reduce interference, the problem was there, but it wasn't severe. Weak signal work could suffer some interference, but the problem was not as bad as we expected. Best of all, the combined efforts of our Alpha 374 and Dentron MLA-2500 amplifiers did not cause any interference to the RTTY system, even while operating RTTY and SSB simultaneously.

This is the dilemma that hams face when they go shopping for a microcomputer-based RTTY system: Do they buy a completely RFI-proofed system that offers limited or non-existent use as a separate computer, or do they go for a microcomputer and interface system that can be extremely useful when the bands go dead, but may or may not need some work to clean up RFI? If getting dual usage out of your equipment appeals to you, the Crown Microproducts ROM-116 deserves your attention; it's a first class piece of gear that you'll never grow out of. For further information, contact *Crown Microproducts, PO Box 892, Marysville WA 98270.* Reader Service number 478.

REALISTIC PRO-2008

Radio Shack's latest introduction to the scanner market, the PRO-2008, provides the Public Service Band enthusiast with an interesting blend of traditional and unique features. The new, stay-at-home relative of the popular PRO-2001 is designed to be a lower-priced alternative for those whose listening needs require a smaller number of channels without a searching capability. The 2008 is a 1980 addition to the Realistic family of scanning monitors and is midway in price and performance between the most expensive crystal-controlled scanners and the more sophisticated synthesized models.

The 2008 is a programmable FM scanning receiver with direct keyboard entry system, capable of scanning any eight frequencies in the ranges 30-50, 144-174, and 410-512 MHz. The entire unit is controlled by an onboard microprocessor designed especially for use in this scanning monitor. The microprocessor is accessed via the 18-key

A $10 Phone Patch

—CQ Ma Bell

You don't *have* to spend $40 to $90 for a phone patch to match your new solid-state rig. This simple circuit will give perfectly adequate performance with parts purchased at your local Radio Shack. For a cost of under $10 and one evening's work, you can have a patch that will work with a new solid-state rig or an older tube-type transceiver. This circuit (or variations of it) has been in use by several hams in this area for a number of years (see Fig. 1). With the bypass capacitors shown, no effect from rf feedback has been experienced, even when used with a kilowatt.

S1 is a four-pole, two-position switch (Radio Shack 275-1384 or equivalent) used to switch the patch on and off. The fourth section of this switch (S1d) is used to switch the patch into the circuit in place of the usual station microphone. If your rig has a phone patch input, you can leave the mike connected to its usual jack and use the alternate connection shown by the dotted line.

S2 is a DPDT toggle or lever switch. It allows you to select XMIT (transmit) or RCV (receive) from the front panel of the patch, rather than fumbling with the microphone PTT switch, telephone handset, and receiver audio gain control all at once.

S2 is wired in such a way as to permit operation with many types of solid-state rigs. These rigs often have the novel little problem that the receiver audio is not cut completely off while in the transmit mode. During normal operation this is not a problem. However, with many of the usual phone patches, an audio oscillation will result, with the phone patch acting as the oscillator coupling element. Switch S2 disconnects the receiver audio from the patch when in the transmit mode, thus eliminating the problem.

The second section of this switch (S2b) grounds the PTT line when you wish to transmit. On a few of the new rigs, this line is called MOX rather than PTT. MOX stands for Manually Operated Xmit, similar to VOX for Voice Operated Xmit.

Impedance matching is provided by T1 and T2, which are identical 8-Ohm-to-1000-Ohm (center-tapped) audio transformers. Radio Shack lists this item as 275-1384. They are not critical, and any 8-Ohm-to-1000-Ohm or 8-Ohm-to-500-Ohm audio transformer will do. Good performance has been obtained even with a pair of 12-volt filament transformers. The 12-volt secondary is connected in place of the 8-Ohm winding and the 115-volt primary in

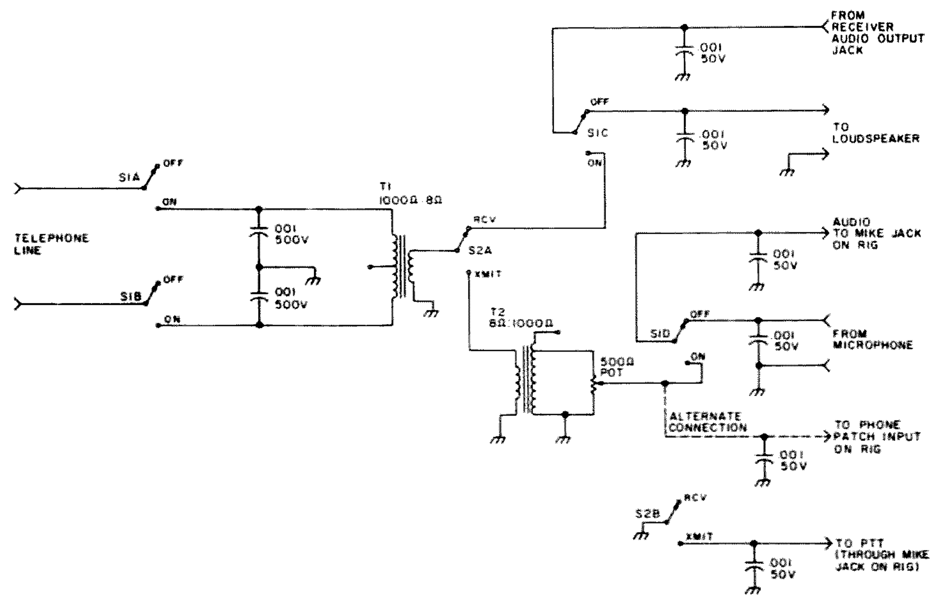

Fig. 1. Inexpensive phone patch uses readily available components.

place of the 500- or 1000-Ohm winding.

The transmit level is set by the 500-Ohm pot connected to T2. Bypass capacitors are shown on all input and output leads to prevent rf feedback. A metal enclosure for the patch is recommended.

To use the patch, set S1 to ON and S2 to RCV and listen on the telephone handset. You can get a clear line (no dial tone) by dialing the first digit of a local exchange. Tune in a station on your receiver and set the audio gain control on the receiver for a comfortable level in the telephone handset. Telephones are quite tolerant and level setting is not critical. If the audio sounds comfortable in your ear on receive while listening through the telephone handset, it probably is acceptable.

Next, put S2 in the XMIT position and talk normally into the telephone handset. Set the 500-Ohm pot so that the meter on the final in your rig swings into its normal area as though you were using the station microphone.

There is no provision for VOX operation. Most hams prefer manual RX/TX since it both prevents an operator's accidental sneeze or cough from turning on the transmitter and allows you to cut off the speaker if he or she attempts to say something inappropriate for transmission over your station.

One tip on phone patch use—for some reason, when you tell someone on the telephone to talk louder, they will do so for a few minutes and then lapse back to their orginal volume. However, if you turn the audio gain control down so that they hear the other station more softly, they will automatically speak up as though to compensate.■

Two Stations on One Antenna

—Impossible? Guess again!

Charles Trice WA4RRB
50 N.W. 189 Terrace
Miami FL 33169

Phillip Vitrano WB4INC
40 N.W. 189 Terrace
Miami FL 33169

Can two amateurs live next door to each other and operate in harmony with *one* antenna system for *two* shacks? Sure! Here's how we did it.

At the time I (Charlie WA4RRB) moved in next door to Phil WB4INC, we had a few things going for us: (1) We had been friends for many years. (2) Our shacks were to be very close. (3) We had a lot of parts in the junk box. (4) And, most importantly, we agreed that it would be ridiculous to have two complete antenna systems side-by-side. We couldn't both operate on the same band at the same time, anyway.

We ended up with a very versatile and simple switching system that features: (1)

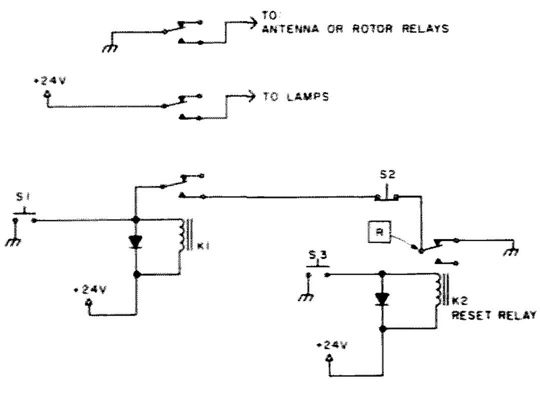

Fig. 1. Basic control relay hookup.

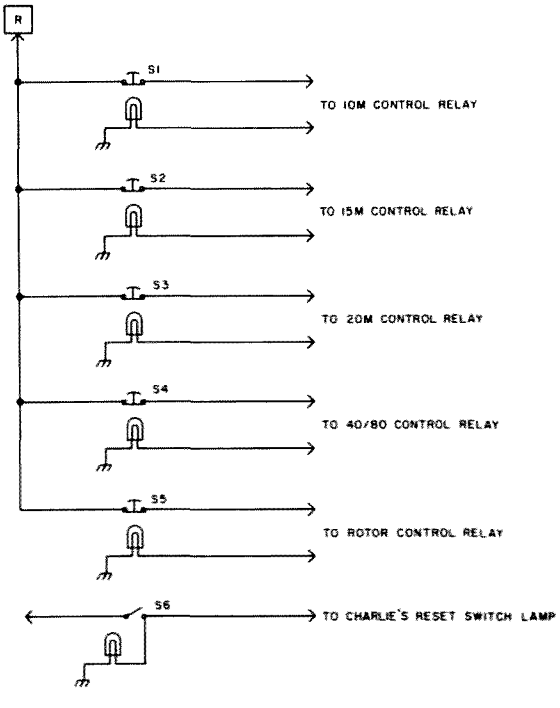

Fig. 2. Phil's control panel.

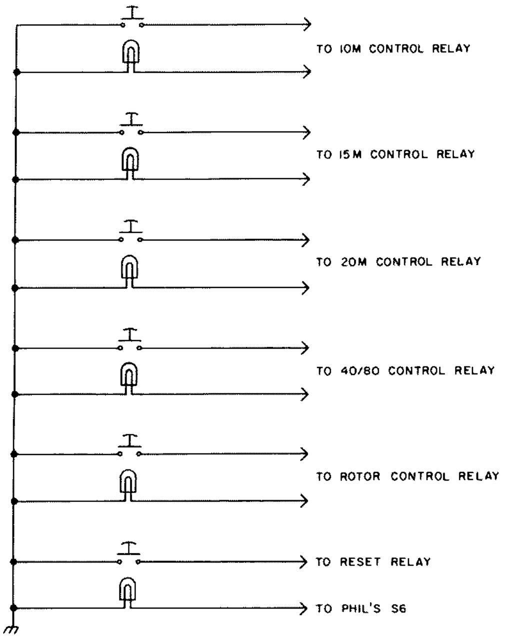

Fig. 3. My control panel.

two-way intercom between shacks; (2) remote control of all the separate feedlines for a three-band, two-element quad for 10, 15 and 20 meters; (3) remote control of a two-band trap dipole for 40 and 80 meters, and (5) lighted indicators.

Since all of the antennas already existed at Phil's, we left them there and I undertook the construction of the switching system. The design considerations were: (1) as little disruption to Phil's shack as possible; (2) a low control voltage between shacks; (3) fail-safe normals so that power supply failure would not inconvenience Phil (after all, I was saving lots of bucks by not having to buy and erect an antenna system); (4) a simple single-voltage power supply; (5) grounding of all antennas when not in use, and (6) ability to override the other shack—if one operator forgot to clear his control panel, the other still could gain access to any antenna.

There are four sections to the system: the control relays, Phil's control panel, my control panel, and the antenna relays. The basic control relay hookup is shown in Fig. 1.

If I press S1 (a momentary NO SPST push-button switch), K1 pulls in. The lower set of contacts applies a latching ground to the relay coil through two dependent normals: S2 (an NC momentary push-button switch) and an NC set of contacts on K2. S2 is on Phil's control panel and when it is pressed, it resets the condition that S1 set. K2 and S3 allow a momentary break in the ground used to latch K1. I use S3 to reset anything I've remoted. Phil uses S2 to reset the relay if I walk off and leave something remoted.

Point R is connected to all of Phil's switches, allowing reset of any remote condition to my shack.

S1 and S2 have internal lamps that are lighted when K1 pulls in. The lights indicate a remote condition. All bulbs are 28 V dc running on 24 V dc to lengthen life. All control relays are 4PDT 24 V dc.

This circuit is duplicated five times: four for the antenna relay control and the other for rotor control.

S6 is a push-on, push-off SPST switch with an internal lamp. Phil presses S6 when at the rig, illuminating my reset switch lamp (in S3) and warning me of Phil's operation. I check with Phil over the intercom to see what antennas are available.

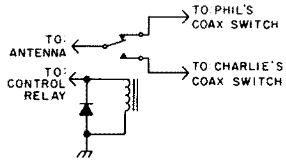

Fig. 4. Antenna relays.

All control switches are momentary SPST push-buttons with internal lamps.

We home-brewed the antenna relays, not only because of the availability of parts in the junk box, but also because of the cost of commercial units. The relays were enclosed in small aluminum miniboxes, with all coax connections made through SO-239s. We feared an impedance lump, but were pleased to find no change in the operation of any of the antennas. The relays used were 24 V dc with large contacts, capable of handling a kilowatt. We also were pleased that no rf got back into the power supply.

The outputs of the antenna relays feed ground-shorting rotary coax switches in both shacks.

All interconnecting cables run between the two shacks through four-inch PVC pipe that is buried about six inches down. The elbow connections into the shacks are hidden from the street with bushes and ferns.

We are able to operate simultaneously, even when both stations are using the quad. The only conflict that arises is in the direction the quad is pointed. Remember—we're friends. . .

The system has been in continuous operation for over two years, with not one failure. ■

Build a 60-Hz Frequency Monitor

—keep the power company on its toes

How many times have you needed a simple, cheap, 60-Hz frequency indicator? Sure, a commercial reed-type meter is nice, but it never seems to be available when you need it. The other alternative, the station frequency counter, is bulky and expensive.

Here is another device—a circuit—which can resolve cycles per minute and costs only a few dollars to build. The circuit is basically a frequency comparator, and the idea can be extended to almost any frequency you wish.* Fig. 1 shows the schematic. The reference frequency (60 Hz) is derived by using a color-TV crystal and an MM5369 programmed divider (integrated circuit). Both crystal and IC are very reasonably priced and useful for many digital clock/timer projects as well. The input frequency is taken from the low-voltage secondary of the power transformer. The power supply is straightforward, using a bridge rectifier and a 5-volt IC regulator, U6.

*"Circuits²," *73 Magazine*, July, 1977, p. 35.

The reference and the input frequencies are processed by the Schmitt trigger, U2, and fed to the comparator circuit, U3, U4, and U5. U3 provides identical pulse shapes to U4. U4 is a 4-bit counter which counts up with one input and down with the other. The counter contents are decoded by U5 and used to light D5 to D8, in sequence. The direction of the sequence will indicate whether the input frequency is fast or slow. For the display, I used a 7-segment readout with a defective segment, but four standard LEDs work as well.

The PC artwork I used is shown in Fig. 2, and parts placement in Fig. 3. Any method of construction you find convenient to use with ICs is okay. Nothing is particularly critical, but you may need 0.01-uF bypass capacitors for the 7400-series ICs. U6 should have a small heat sink.

It's simple to use. Plug it in and watch the rotation of the LEDs. For the most part, the oscillator trimmer doesn't really have to be adjustable. If you're a purist, the oscillator can be set to 3.579545 MHz with a frequency counter on U1 pin 7, a buffered output.

Plug it into your local power company, and you will see a very slow rotation, once every five minutes or so, corresponding to a frequency difference of perhaps four cycles in five minutes. Most power companies rarely hit 60 Hz on a

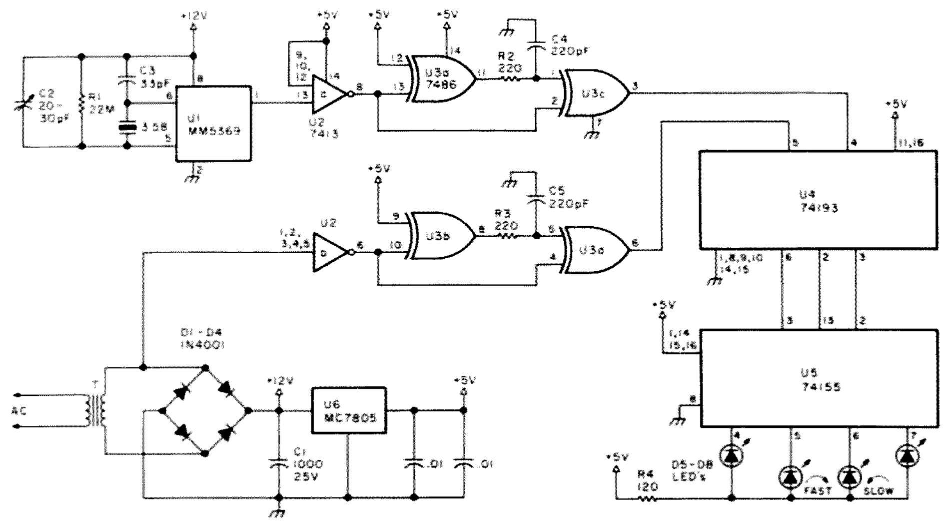

Fig. 1. 60-Hz comparator schematic.

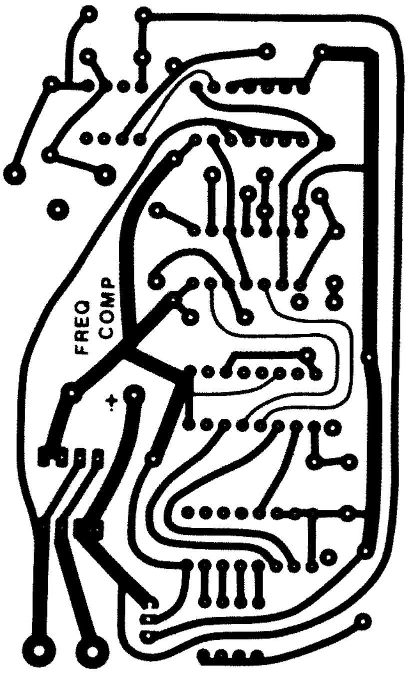

Fig. 2. PC board layout.

short-term basis because of adjustments needed for demand, etc., but over the long term, all the clocks stay on time. This is why the rotation will be fast (clockwise) at some times while slow (counterclockwise) at others. On an emergency or standby power system, you will see quite wide changes of frequency with load variations.

That's all there is to it. One of these devices is in use at a local radio station. (Opening the throttle on a 30-kW diesel generator until the fluorescent lights fire is not the best way to set engine speed!) Try one for Field Day.

I want to thank Carol Stoops and Keith Anderson for the photography, and Lindsay Mickler for her assistance in preparing this manuscript. ■

Feelin' No Pain

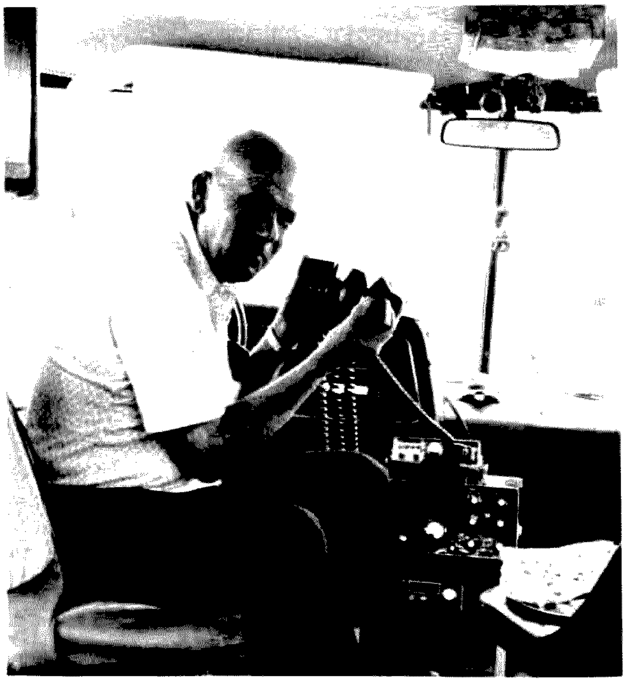
—expedition to Luckenbach

Permanent residents of Luckenbach, Texas, whose numbers fluctuate between three and five depending on the time of year and which way the wind is blowing, took the whole thing in stride on that May weekend.

And why not?

On previous weekends, for instance, thousands of country-and-western-music fans had jammed the tiny Texas hill country community to listen to their heroes, Willie Nelson and Waylon Jennings, sing the praises of Luckenbach ("where ain't nobody feelin' no pain") and drink beer.

Other weekends brought numbers of Bandidos (the Texas answer to California's Hell's Angels) roaring down Luckenbach's main street on their motorcycles for days of dancing and drinking beer.



"Tex" N5TX offers a handful of mikes from inside his mobile home's main operating and driving location. The vehicle served as one of the many operating points during the weekend.

And, on weekends between, there is a constant stream of curious tourists, carrying cans of beer and admiring such well-known landmarks as the town's lone parking meter, the recently installed pay telephone (the only one in town), or the bust of the late Hondo Crouch, who helped rescue Luckenbach from becoming a ghost town by buying it—lock, stock, barrel, and egg-delivery route.

What was so special about the arrival on the weekend of May 12-13, 1979, of several dozen radio amateurs (with their elaborate equipment and antennas) for the first DXpedition to Luckenbach? For the locals, not much—except for another increase in beer sales. Few passersby noticed the sounds of CW signals drifting over the row of faded green outhouses across from the combination general store and bar.

But if the regulars were being blasé about the DXpedition, amateurs around the world were not. They were lined up, waiting their turn for a contact with W5TEX, the Voice of Luckenbach, for the weekend. When the pileups cleared at noon Sunday, after twenty-eight hours of operation, some 2,200 amateurs had qualifed for special certificates issued for the occasion. And some of those pileups were so massive, operators and loggers occasionally had to summon help.

One of those waiting to land W5TEX was UA9DO in Moscow, who read about the DXpedition in a US ham radio magazine. That particular QSO was the longest distance worked during the weekend. (One Texas ham wondered why the Russian apparently was getting better and speedier delivery of the magazine than were the locals.)

Other DX logged included WA4JHS/MM1 in the Mediterranean, SV0AH in Greece, YU2RAW in Yugoslavia, and EA9FE in Africa, all on 10 meters.

And there was the bewildered WB2RLK/VE1 in Nova Scotia, who could not immediately grasp the details of his QSO with Luck-

Larry N5LL handles the 10-meter and 6-meter FM positions from a relaxed perch just aft of the tailgate of a vehicle.

"Cherokee" WD5JKW at the key on 15-meter CW, one of the most active operating positions in Luckenbach.

enbach. Dee WB5VWX and Floyd WB5PFR found an old set of bedsprings, took it outside, propped it up, loaded a Ten-Tec Argonaut into it through a tuner, and worked him on 10 meters, getting a respectable 5-by-5 report in return. They said later that they had to twice explain where they were and what was happening with their antenna; they quoted him as saying that "since he was working a station in Luckenbach, he could believe almost anything." That QSO netted him the only bedspring endorsement to be awarded on a certificate. The antenna was dismantled immediately afterward.

The whole event, staged by the Bexar County Repeater Organization in San Antonio, was timed to coincide with the annual return of the mud daubers—an occasion rivaled only by the return of the swallows to Capistrano or the return of the turkey vultures to Hinckley, Ohio. And the mud daubers (pronounced "muddobbers" locally) winged in promptly at noon on Saturday to be greeted with cheers (and another round of Lone Star beer) from the crowd that had gathered to mark the event.

Operations were set up in a former cow pasture, adjacent to the main street, vehicles were deployed around the area, and the place soon took on the air of Field Day. Stations were set up in mobile homes, travel-trailers, on the tailgates of pickup trucks, and in a nearby building.

Beams (lent by Wilson Electronics Corp.) and longwires were everywhere. In many instances, the beams were cranked by hand.

Using regular power sources instead of emergency generators, the operators jumped to their tasks just after breakfast on Saturday. Sixty-one operators and loggers manned the various points, with stations on all the high-frequency bands and on 6 and 2 meters in the VHF spectrum. Phyllis Dyer WB5ZFA put all the other operators to shame by handling 291 out of 582 contacts on 20-meter phone during the weekend. And there were 524 contacts on 40 phone, 498 on 15 phone, and 205 on 15 CW.

The idea for the outing came (as a joke) from a repeater organization member to Bob Schneider AI5Q, who was the net control station one night.

"Clem WB5VDL said he was turning the net back over to AI5Q, who was organizing a DXpedition to Luckenbach," Schneider recalled later. "Everyone heard it, and the next thing I knew, we were getting calls from as far away as Corpus Christi wanting to know about it."

From there the idea caught on and spread. The repeater group raised about $1,200 through a raffle to finance the costs.

Tentative plans call for the San Antonio group to mount its next DXpedition from deep in the heart of Texas—literally. The next outing has been scheduled for mid-1981 from a cavern below the surface of the earth—a cool spot on hot days.

Other sites being eyed are Terlinqua, Texas, near Big Bend National Park in far west Texas and the site of an annual chili-cooking competition, and Lost Pines, near Bryan, Texas. Legend has it that Lost Pines, located in an area of the state otherwise devoid of pine trees, came from seeds planted by the famous Johnny Pineseed, a descendant of Johnny Appleseed, who wandered that section of east Texas in the last century and whose exploits are expected to be the center of attention any day now, according to Schneider.

Any chance of a return trip to Luckenbach?

"That's possible, too," Schneider said. "They were glad to have us and happy about the publicity. We were so tame compared with the normal Luckenbach groups that we almost weren't noticed. We probably were the first group in three or four years that didn't have hair down to our shoulders."■

Operating Overseas
—licensing facts for traveling hams

Early in 1977, after having passed the radio amateur examination in South Africa, I had to travel for my company to the German Federal Republic. In South Africa, I could find no information readily available on how to obtain permission to operate in other countries. A phone call to the DARC (the Deutscher Amateur Radio Club) amateur radio center, the Amateurfunk-Zentrum (AFZ) in Baunatal, West Germany, brought me all information on how to get a guest license.

After returning to South Africa, I discussed my experience with other hams. It became clear to me how many of us travel but leave our rigs behind and do not apply for permission to operate in the countries visited because there is just no one who knows who to contact for such permission. Subsequently, I wrote to the DARC and got photostats of all the guest license information available at that time (early 1978). The information supplied by the DARC is, of course, intended for German radio amateurs and is based mainly on arrangements the German Ministry of Posts has made with other foreign telecommunication authorities.

This was used as a basis for finding out the conditions under which foreign telecommunication authorities issue licenses to visitors. When I visited the UK and West Germany early last year, I was lucky to meet the General Manager of the Radio Society of Great Britain (RSGB), OM Dave Evans, in London, as well as the General Manager of the DARC in Baunatal. We discussed problems that visiting hams encounter, and I was now able to help the DARC update its guest license file with information from South Africa and elsewhere.

The information contained in this article has been gathered from various trips that other hams and I have made. Guest licensing is in a stage of rapid advancement as more hams travel and licensing authorities realize the needs and benefits—especially in developing countries.

Let's take now a look at how various countries grant licenses to visitors.

Reciprocal Agreement

Countries which base licensing for visitors strictly on reciprocal agreements only are, for example, Austria, Denmark, Great Britain, Switzerland, and the United States.

● *The United States:* Licensing for visitors is based on reciprocal agreements between two licensing authorities, in which both parties to the agreement state which license classes are equivalent and are recognized by each other.

● *Great Britain:* The Home Office in London is the British licensing authority dealing with application from visitors. Between the UK and South Africa, a reciprocal agreement has already existed for quite some time. However, a large number of radio hams traveling from South Africa to the UK were not born in South Africa. There are, for example, British passport holders who participated in the classes of the Johannesburg branch of the South African Radio League, as well as other non-S.A. nationals who passed the amateur radio operators examination in South Africa.

The agreement states that each license authority will recognize each other's exam certificate provided

the applicant is a national of the country where he passed the exam. I pointed out that this would exclude the non-S.A. citizens who are permanent residents in South Africa. The Home Office spokesman indicated that new consideration would be given to this matter. Nobody had realized that this wording could be discriminating.

Guest Licensing

The Ministry of Posts in the German Federal Republic, along with other European countries, started in the sixties to conclude agreements with other countries to cater to traveling German hams and for the visitors. The general liberalization in Germany and other countries led to a new type of permission to be introduced. The guest license (also called short-term permit in some countries) is not based on a bilateral agreement anymore but on the merits of the individual applicant. This eliminates a lot of paperwork and politics for the administrations.

Any radio ham holding a valid amateur license in his/her home country can apply for such a guest license. A basic requirement is that the examination passed in the home country be equal to or of a higher level than the class applied for in the country to be visited. For example, in the US the Technician class license is similar to the class "A" in the German Federal Republic, but the Novice license is not equivalent to the German class "C" because of differences of depth in the theory and the absence of a CW test in the "C" license.

Belgium, France, West Germany, and Israel are countries which issue guest licenses without a reciprocal agreement in force.

● *Australia:* A visitor permit is issued on application for a period of up to 12 months for a fee of $A12, provided the visitor is a bona fide tourist and does not intend to enter the country to take up employment. Radio hams arriving from countries where a reciprocal agreement exists with Australia will be given an Australian license even if they take up employment. Arrivals from non-agreement countries wishing to take up employment have to sit for the exam.

● *Swaziland:* A visitor permit is issued on application to hams originating from ITU-member countries for a period of up to 30 days free of charge (include an IRC for airmail reply). Applications for permanent callsigns from hams arriving to take up employment will be considered (through a security check) once they are resident.

Swaziland, a beautiful mountain kingdom with a wealth of tourist trade mainly from South Africa, is not super-rare DX, but there are many hams who do not have a QSL card.

The Swazi Telecommunications Department has been acquainted with amateur radio since its start and visitors have always been allowed to operate. Applicants, however, sometimes did not have an answer after waiting for six months and more. When in Mbabane, the capital, I went to see Mr. B. Manana, the man in charge, who explained the problem to me.

There was no application form available, and hams simply wrote letters indicating the period they wanted to operate and enclosed photostats of their current license. If all required information was provided, a permit was granted. Where the application was incomplete, it was filed. The basic problem was that applicants did not know what they were supposed to do.

I developed an application form which covered all questions to the satisfaction of the administration, and to my knowledge no completed application has since been unsuccessful.

● *Zimbabwe Rhodesia:* Short-term permits are issued free of charge on application from visiting hams originating in countries where no reciprocal agreement exists, provided the application is received at least six weeks before arrival in the country.

● *South Africa:* The South African Telecommunications Department bases its licensing decisions for visitors on reciprocal agreements only. At the AGM of the South African Radio League in Durban in 1979, a motion was passed unanimously to appoint a committee to investigate guest licensing for visitors to South Africa.

Reciprocal Licensing vs. Guest Licensing

Reciprocal Licensing. This has the advantage that US hams are granted the same privileges as visitors to the US. This is the same, of course, in all other countries which license strictly on a reciprocal system. Reciprocal agreements place a great administrative burden on the licensing authorities concerned, sometimes for the benefit of only a very small number of hams. The US is a world leader in reciprocal agreements, followed by Great Britain. This effort is very commendable, but not all administrations are prepared to conclude agreements with large numbers of other countries.

Guest Licensing and Short-term Permits. This takes a lot of the work load off the administration, and visitors from rare DX countries can be considered, which is, of course, a lot of fun for the hams in the country being visited. It gives the visitor a better opportunity to meet the locals and make friends. It also is exciting to hear an A2C station mobile in 3D6, a ZS6 call portable ZE, or (when I was in Germany) an A2CPS/DL/mobile on the air. Political differences between countries are not obstacles anymore, and applicants whom an administration might find undesirable can be rejected without any embarrassment.

Where Does the Information Come From?

In my travels, I make a point of visiting the license authorities to obtain application forms, discuss the various aspects of guest licensing, and to maintain a personal contact. You could do the same.

To provide up-to-date information for radio hams, each amateur society should have a current file based on travels by members. Awareness can be created by the editor of the national amateur magazine. In the South African *Radio ZS Magazine*, I have had various articles published which have helped hams to obtain reciprocal as well as guest licenses.

The *cq-DL* also has frequent reports of traveling hams who have visited rare countries, describing their experiences.

It is not in my scope to answer all queries of all US hams traveling the world. However, hams traveling in Southern Africa, including Botswana, Rhodesia, Bophuthatswana and Transkei can contact me for application forms and an information sheet. Please include $1(US) for postage and photostat expenses per country. (Any queries without 3 IRCs for return air postage cannot be considered.) A *must:* Include callsign, license class, proposed date of arrival, and period of intended stay. Please type, or use neat handwriting, and allow at least 60 days. ■

Stalking the Elusive Ground Fault

—a real-life adventure

A. R. Taylor W5OS
Rte. 4, Box 76
Gravette AR 72736

Midnight, and after four hours, I had finally found the semicolon some nearsighted copyreader had overlooked in my BASIC manual. I pulled the plugs and put my toys away.

Early in the evening, there had been flashes of lightning in the area, and the general forecast was for possible thunder-showers. In this part of the Ozarks, that can be bad news, so I made the rounds. First, the garage, where my country-type water system was installed—check water pressure and then disconnect the pump; throw the master switch. Then to the radio shack—all gear disconnected from the power line, antennas properly grounded, everything there OK. Back in the house—two-meter gear disconnected, organ plug pulled, TV antennas and line plug out, hi-fi system disconnected—nothing running there but the electric clock built into the wall. Refrigerator and deep-freeze still connected; pull them only when lightning is making the dog howl. Nothing connected in my bedroom but a cheap radio and a fluorescent lamp; in my wife's room, I knew there was another fluorescent lamp and a clock-radio; they should all be OK. About twelve-thirty now, and it had been a long day. Even the dog was asleep.

Two-thirty. *"Bob, I need your help!"*

I reckon she did—house full of stinking electric-type smoke. Wife's fluorescent lamp in flames; electric clock dead. Bulb in the ceiling with a dull glow. Pulled beds and dressers around to get at various outlet boxes; nothing wrong. (Still not awake.) Out in the kitchen, refrigerator not running—oh, boy! Those things cost money! Utility room, deep-freeze not running; they're expensive, too. Pulled refrigerator plug. Pulled deep-freeze plug—hey! Lights came on bright.

So, problem solved. Pretty good for me. Back in the days when the Kaiser was invading Belgium and Rickenbacker was learning to fly, I used to be able to solve little problems like this, and I still could, by golly! So—must be the deep-freeze. Plugged the refrigerator back in; lights went out. Good grief, refrigerator *and* deep-freeze; half a year's social security!

Plugged in the coffee pot; the lights went out. Make coffee on the gas. Plugged in the toaster; the lights went out. The Kaiser was getting near Paris by this time, and it dawned on me that I still had a problem. (Rickenbacker was looking for the Red Baron.)

Out to the shack for a voltmeter. (Hey! It's cold out here for a guy my age running around in pajamas.) Then to the utility box to check circuits. No definite conclusion. Let's start at the beginning, the power pole out in the yard, where I had a master circuit breaker.

It's dark; screwdriver to get into box; careful, you drop that damned screw, you'll never find it in the grass. Box open, screw in bathrobe pocket, voltmeter in one hand, probes hunting screws on 220-volt line, flashlight on probes, need light on voltmeter, need two more hands; it's dark. Got reading—110 on one side, 125 on other side of line. So what does that tell me that I hadn't already guessed? Try to shake 75 years out of my mind—doesn't shake.

Replaced cover on circuit-breaker box. Returned to house to drink coffee my wife thoughtfully brewed on gas range. Stopped shivering after a while. Let's analyze this thing. Garage and water system completely disconnected—couldn't be anything wrong there. In the shack, maybe? Told wife to go back to bed. Pulled master circuit-breaker in house and went out to shack with toaster in hand. Plugged in toaster, lights got a little brighter; plugged toaster in on the other line, lights went out. Ah ha! Trouble in

the shack. I knew early in the game that it was a ground-fault problem I was looking for, but how to find it in my pajamas at four o'clock on a cold morning? Better call the power company, if our rural phone is working. First, though, let's be sure.

Pulled the master switch in the shack, went back in house, threw that breaker back on, and plugged in the toaster. The lights went out. So it isn't the shack, it isn't the house, it can't be the garage; what the heck was that power company number?

Electric company office fifty miles away, but it's an "800" number. Found it; telephone is working. Ringing. Ringing. Ringing. Very sleepy voice answering. I tell him I have a problem. He asks what's wrong. I tell him. He says I have a problem.

After a while he wakes up, too, finds out where I live, and says he will send a crew. The last time the power company "sent a crew," it turned out to be a couple of smart young linemen who wanted to teach "grandpa" how to suck eggs, but maybe they've got more than one crew. Time passed. I got dressed. Warmer now; stopped shivering.

Lights coming down the gravel road. Stopped at my driveway. Glory-be, help has arrived. This is a different crew: Didn't believe in arguments at five o'clock in the morning, agreed I had a ground-fault problem, noted the ladder against the house and commented that I had already checked that connector. Told them that I had, but suggested they check it anyway. Said they would, but would "check our stuff first." Restarted their truck motor and fired up a pretty good searchlight, put on spurs, and climbed the utility pole. Wiggled the connector on our incoming ground line and the lights in the house flickered! Tightened connector and told me to try my toaster. Tried toaster; it heated and lights stayed on. Plugged in the refrigerator and the angels were singing and so was the frig. Tried deep-freeze; wife's face fell—no new deep-freeze.

Line crew replaced connector, also another like it on the transformer pole a few yards away (sort of sleep insurance).

Greeted the sun with coffee all around. Line crew told me that they had just got into bed after an emergency in a town across the county when they got the call sending them to me. Figured now it was too late to go home and to bed; might as well get ready and go to work.

Wife gets ready and leaves for work. I don't work (so she tells me). Dig into clock radio. Transformer shot. Got one, little bit too big, but it will do until I get a proper replacement. Installed transformer and clock back in business. Hooked it up in bedroom, shut off radio, wouldn't shut off! Now what? Disconnected clock, remembered gremlins, reconnected clock, switch now works.

Dig into fluorescent light. Loading coil a bundle of tar with two leads sticking out. Checked with a voltmeter and had continuity. Whadayaknow; just melted the leads and the tar and made a stink. Cleaned tar, soldered new leads, potted coil in epoxy, replaced bulb, light works. Still stinks.

Wife says I'm a genius. Don't tell her that I'm not smart, just cheap! ■

Wells Chapin W8GI

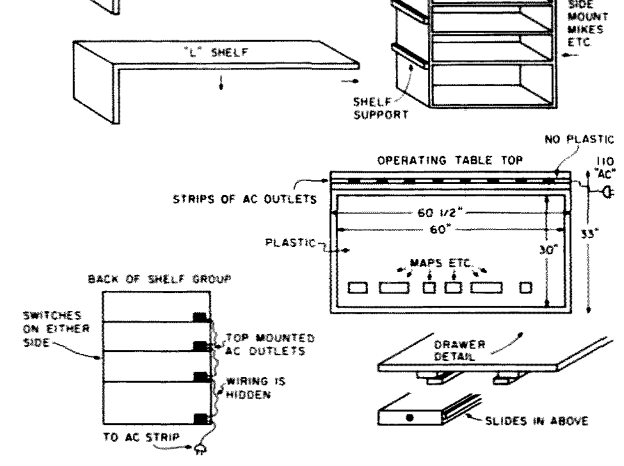
Kingsley MI 49649

An Operating Console with Class

—customize to your heart's desire

Take a look at the W8GI operating console in Photo A. Total cost of this console arrangement was $85. It is easy to build, and it makes moving of the equipment and console to other places simple, as the whole arrangement breaks down into lightweight pieces. You don't have to heave around a heavy desk, you can customize it to your purposes, it is expandable, and you can remove any unit without changing a panel or removing screws. It takes out all the haywire in the shack, puts all your operating aids such as maps in clear view at all times, keeps your *Callbooks*, pencils, etc., handy, makes operating a pleasure, gives your equipment a professional look, and last but certainly not the least, it will keep the wife happy.

This article is not intended to be a detailed construction article. It is only an idea article with enough details to enable you to customize your own installation. Nearly everyone can use a few of the ideas to expand a present operating setup. The shelf-group idea can be applied to any desk—*et voilà*—you have a



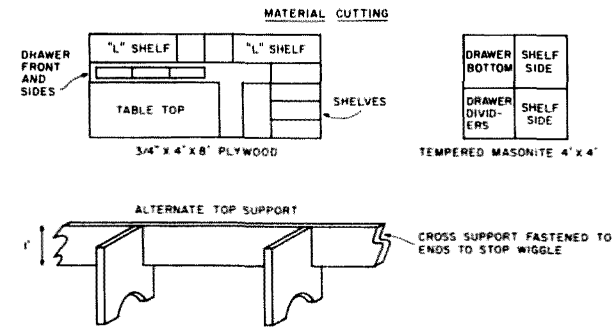


Fig. 1. Suggested layouts and construction details.

custom setup with a minimum of work and cost.

The only tools you need are an electric hand saw, plane, file, hammer, nails, small screws, stain, and sandpaper. Material required is a 3/4″ × 4′ × 8′ piece of plywood, a 4′ × 4′ piece of tempered Masonite™, a piece of storm-door plastic to fit the top of your console, two three-drawer unfinished cabinets, 18 feet of 1/4″ × 1″ stripping or screen molding, and a strip of 110 V ac plugs. All the material was purchased at our local K-Mart store. You can eliminate the three-drawer cabinets by buying a 4′ × 4′ piece of plywood and making your own ends.

The first step is to decide how large you want your operating table. I chose 33″ × 60″ because it is wide enough and long enough, and just fits a standard 30″ × 60″ storm-door plastic panel. This makes it cheaper, and you do not have to cut the plastic. You should decide what shelf-group you want, and design it with the number of shelves you want—with the depth, width, and height you desire. Be sure to consider possible later expansion.

The old Crosley Model 52 and other units are on an L shelf that simply sits on a support on the side of the shelf-group, and the L portion rests on the operating table. You can add as many of these L shelves as you want by installing another small support on the side of the shelf-group and adding another L shelf that sits on top of the first. Details of this arrangement are shown in Fig. 1. Be sure to leave room at the top of the operating units for free air circulation. Notice the shelf-group on the right that is within easy arm's reach. The L shelves are supported on one end by a 1-inch square × 10-inch support glued or bolted onto the side of the shelves.

Masonite is used for the sides of the shelf-group because it is only 1/8-inch thick, and thus you can mount short-sleeved switches without any trouble. The microphones are mounted on one side of the shelf. Top-mounted ac outlets are positioned on the rear of each shelf and are wired together, starting at the top and ending at the bottom with a pigtail plug lead that goes to the ac strip on the rear of the table. The wiring is concealed on the inside back of the cabinet. Glue a piece of felt on the bottom of the shelves, as this will stop scratching of the plastic top and keep it from sliding.

Fig. 1 shows suggested layouts and some construction details. Also shown is a layout that will enable you to get all the pieces out of a single sheet of plywood and one piece of tempered Masonite.

The following are helpful hints that resulted from my experiences when building the console. You can use 1/4″ × 1″ stripping or screen window trim to put a finish on the edge of the plywood. One side of the plywood is fine-finished, and all it needs is fine sanding and a light coat of stain. Drill the holes in the plastic top along the edges before you put it on top of the operating table, as when the drill goes through, you have small chips that are unsightly and raise the plastic.

Place your operating aids, maps, DX prefixes, charts, etc., on the table and arrange to suit. Be sure they are back far enough from the edge of the plastic top. When you get the final arrangement, take small pieces of tape and hold them in place, because if you don't, when the plastic top is dropped down the air

Photo A. The W8GI operating console.

will rush out and disturb everything. Mount the ac plug strip across the back of the table and right up against the plastic top, so that there is no hole to collect dirt. Don't forget to put an extension long enough to reach your 110 V ac line before you snap the strip plugs closed. You will have an inch or so of table showing, but this is unseen.

Happy console-building. It's easy—it's fun—it's rewarding. ■

Add-On Capacitance Meter

—works with your counter

Joe Westenhaver W4FEC
155 Woodfield Drive
Auburn Al 36830

This seven-digit capacitance meter will allow you to accurately check the capacitance of almost any capacitor quicker than you can read the printed value. It also shows leaky capacitors and the polarity of polarized capacitors. It covers 2 pF to 999 uF in only two ranges and consumes almost no power. All this for only $1.28 (2ICs—46¢, 1 diode—16¢, 5 resistors—25¢, 1 DPST switch—39¢).

There must be some catch—of course, there is. You must already own a digital frequency counter. My tester was built to be used in conjunction with a homemade seven-digit counter using an ICM 7207/7208 counter chip salvaged from a Conar model 202 frequency counter, but it should work equally well with other counters.

Theory

Ok, let's see how it works. When a discharged capacitor has a fixed voltage applied through a fixed series resistance, it will charge at a rate directly proportional to its capacitance value. What we will measure is the time it takes to charge our unknown capacitor to some predetermined value.

That's where the frequency counter comes in. We use a flip-flop to obtain a pulse whose width is a function of the charging time and then the counter to count how many clock pulses can pass during the time interval of that flip-flop pulse. A combination of clock frequency, charging voltage, series resistance, and trigger point is chosen so that one clock pulse passes for each 1 pF in the low range, or one clock pulse for each 1000 pF in the high range. With this arrangement, our counter gives a direct capacitance readout.

The capacitance measurement must be synchronized with the count interval of the frequency counter. See Fig. 1. Counting is enabled when pin 13 of the ICM 7208 is brought low (logic 0). Intersil calls this the inhibit input pin. This function is frequently called the gate, and on some counters may be a logic 1 signal. If your counter uses a logic 1 gate, then the optional IC1a gate connection in Fig. 1 can be used to invert the gating signal. Commonly used gate times are 0.1 second and 1 second. The gate time interval does not affect the capacitance measurement except to limit the maximum value of capacitance which can be measured.

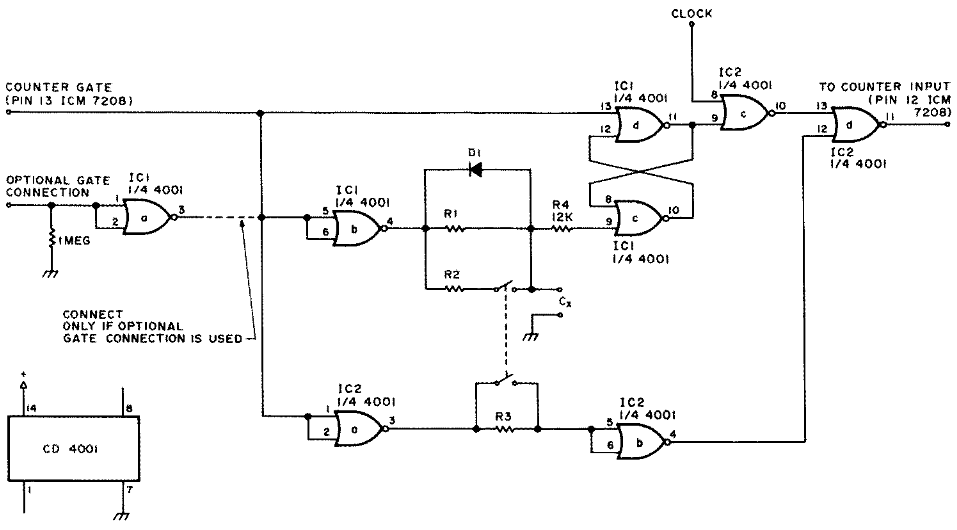

Fig. 1. Capacitance checker schematic.

When the gate signal

goes low, the counter is ready to count pulses. IC1b goes high and starts charging the unknown capacitor through R1 or R2. The flip-flop formed by IC1c and IC1d was reset to a low output when the gate was high. Now its output changes to high after the time delay of charging the capacitor up to the flip-flop changeover point. This time delay is directly proportional to the capacitance value and is the basis of our measurement.

IC2c is initially on while the flip-flop output is low and will allow clock pulses to pass until the Cx time delay expires and the flip-flop goes high. However, IC2d blocks the clock pulses from the counter until the gate goes low and a slight time delay imposed by IC2a, R3, and IC2b expires. This time delay compensates for the input capacitance of IC1c (about 5 pF) and circuit stray capacitances. This allows us to measure accurately right down to 2 pF. R3 is determined experimentally and is about the same as R1. If errors below 100 pF are of no concern, IC2a, IC2b, and R3 can be eliminated. D1 allows a quick discharge of Cx and can be any small switching diode.

Now, about the clock. (Ah, another catch not included in the $1.28!) It must be a stable source of pulses compatible with CMOS logic. The frequency doesn't matter much, but if it is much above 5 MHz, the CMOS chips have trouble. If it is too low in frequency, the ability to measure small capacitors become jeopardized. About 1 MHz seems ideal. Stability should be at least 1%, so a crystal source is best.

Your counter already has a crystal oscillator in it which can probably be used. If it is in the 5-6-MHz range, then a divide-by-5 (½ 74C90) will do the job. I happened to have a crystal marked 1001 kHz and used that in a separate oscillator (½ 4001). Almost any crystal in the 2-10-MHz range could be used with an undertone oscillator.[1] So, I'll leave the source of the clock pulses up to you.

Calibration

Now for calibration. This instrument has two ranges. The low range displays pF and the high range pF × 1000. On the low range, the idea is to have one clock pulse for each pF. Therefore, the time delay for R1 and Cx needs to be the time of one cycle of the clock for each pF. On the high range, the time delay for R2 and Cx needs to be one thousandth of the time for one cycle of the clock for each pF.

For example, with a 1-MHz clock the cycle time is 1 us. Therefore, the time delay for the low range for a 1-pF Cx should be adjusted with R1 to be 1 us. The time delay for the high range for a 1000-pF Cx should also be adjusted with R2 to be 1 us. Thus, with a 1-MHz clock, the maximum value that can be measured with a 0.1-second gate is 99,999 pF or about 0.1 uF. With a 1-second gate, we can go to 999,999 pF or 1 uF. On the high range, we can go to 99 uF with a 0.1-second gate and 999 uF with a 1-second gate. On the high range, the error caused by the input capacitance of IC1c is negligible and R3 is switched out! The values of R1 and R2 depend on the clock frequency and also the characteristics of the particular 4001 chip. The chip characteristics will vary quite a bit from one to another but are stable and predictable in each chip.

Calibration obviously requires some sort of standard. I have found capacitors marked ±10% to be far off the printed value.

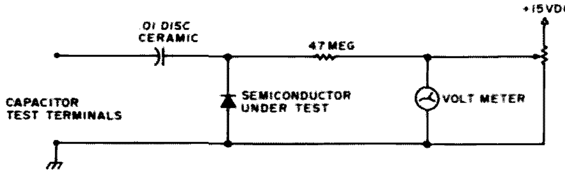

Fig. 2. Semiconductor junction voltage-variable capacitance characteristics test setup.

Also, ±5% capacitors vary considerably. The values marked on most electrolytics are only approximations. I have found silver mica and disc ceramic capacitors which are marked ±2% to be very close, so I use these for calibration.

With 1000 pF ±2% at Cx, I adjust R1 for a counter display of 1000. Then I crosscheck with a 27-pF ±2% silver mica and bingo—27! Once calibrated on the low range with these capacitors, I measure a 0.22-uF molded capacitor (.218752) and select the high range and adjust R2 for a readout of 219.

Obviously, the accuracy is limited in this calibration scheme to the tolerance of the best capacitors you can find. I think, however, that you will find the tester very useful and accurate enough for anything but laboratory work if calibrated to within 2%. With the particular 4001 I have in service and the 1.001-MHz clock, R1 is about 1.04 megohms and R2 is about 800 Ohms. Both R1 and R2 are fixed, with small potentiometers (not included in the $1.28!) in series for fine adjustment. R3 is fixed at 1 megohm.

When connected to a counter, with no capacitor under test, this tester will always indicate a 1 on the last digit. R3 is selected so that a very small capacitor (such as 5 pF) reads correctly. A 1 pF or less then indicates 1 and anything larger will indicate correctly.

With large capacitors there will be a large number of digits displayed. You should ignore all except the first three significant digits. The rest will change after each sampling period, but they have no meaning since you only calibrated the instrument to 1 or 2%. I have never found the reading to fluctuate as much as 1%, and frequently it fluctuates less than .01%.

Operation

The power source for your tester should be stable and can be drawn from your counter if it is between 3 and 15 volts dc. Current drain is negligible.

Now that it is all built and calibrated, let's look at some operating considerations. Leads from IC1c to the test jack should be short to prevent hum pickup. Also, you should keep external leads to the capacitor very short and keep hands off during sampling to keep hum out. Furthermore, you should mount IC1 in a socket to make it easier to replace after you ruin it by not observing a few simple precautions.

Note that the test point connects to an input gate of the CMOS chip. R4 should provide input gate protection up to about 120 volts. Testing a capacitor in a hot circuit can zap the 4001; placing a charged capacitor to the terminals can zap it, too. Large static discharges will also spell the end of the 4001 and you'll be out 23¢ or so. While these precautions seem worth mentioning, in over a year of frequent use I have never harmed the 4001.

If your counter has a 0.1-second gate, you will want to use it most of the time. This means the longest you will have to wait for

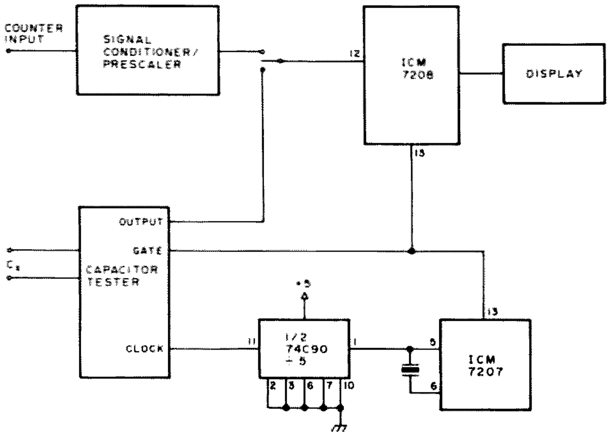

Fig. 3. Suggested interconnections for capacitance checker, counter, and timebase.

your reading is 1/5 of a second. With a 1-second gate, it might take 2 seconds. A leaky capacitor will indicate much too high of a value. Just a small amount of leakage will cause a little disc ceramic to read out 999 uF. You will not see this often, but when you do, throw that one away.

Polarized electrolytic capacitors usually have leakage when the correct polarity is not observed. If you test one by connecting it to the test terminals in both directions and get the same reading each time, it is probably non-polarized. If you get considerably different readings, the smaller reading is correct and indicates the correct polarity. Of course, the correct way to connect electrolytics is the − (minus) to ground and the + (plus) to the test point.

Lots of fun can be had testing trimmer capacitors, crystal holder capacitances, transistor input/output capacitances, twisted wires, coax, etc. All can be easily measured. The voltage-variable capacitance characteristics of semiconductor junctions can be easily observed by using the hookup shown in Fig. 3. Keep all leads as short as possible to prevent hum pickup.

I have found that selected zener diodes exhibit very nice large capacitance varactor characteristics up to their zener voltage. Selected silicon transistors with their base/collector junction reverse biased make nice, small-capacitance varactors. And, of course, you can test a standard varactor to see if it covers the desired tuning range for a voltage tuning application. The best application of all is to turn that junk box full of poorly marked capacitors into a supply of useful components of known values.

You don't have a frequency counter? Shame! Run right out and buy one, or better yet, build one such as the $50 Mini-Counter[2] and incorporate this tester inside. For $1.28 (or so) you can't afford not to! A suggested interconnect block diagram with the ICM 7207/7208 pair is shown in Fig. 3.■

Better Pilot Lights

—LEDs are the "in" thing

After having a vfo pilot lamp burn out prematurely in my T-599D, I decided to replace the lamp and red lens with an LED. Referring to Fig. 1(a), the red lens is held in place with a small amount of cement, and is illuminated by a lamp positioned close to it.

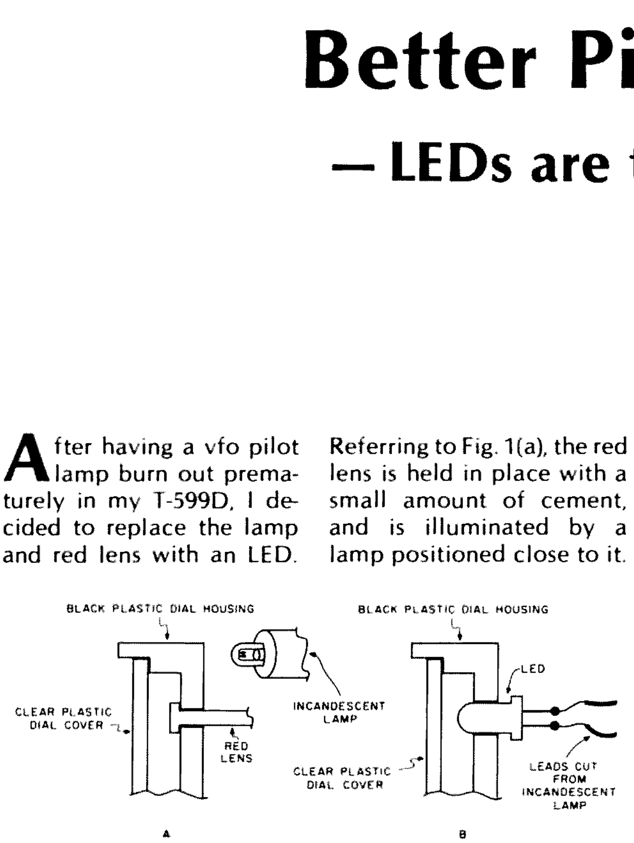

Fig. 1. (a) Cross-sectional view of Kenwood's vfo pilot light system. (b) Cross-sectional view of LED vfo pilot light system.

The red lens may be removed easily after cutting away the cement. After removal of the red lens, the hole is slowly enlarged with a reamer to the point where the LED fits snugly in the hole (caution should be exercised, as the plastic plate is very soft and one easily can exceed the desired hole diameter).

Referring to Fig. 1(b), with the LED in place, the clear plastic dial cover should fit properly in the black plastic housing. Next, apply some cement to the rear of the LED and housing to hold the LED in place.

The leads cut from the lamp are soldered to the LED. It is necessary to insert a 1200-Ohm, ½-Watt resistor in series with one of the leads to the LED. It is convenient to place the resistor on the solder terminal that the lamp leads are attached to, and in series with either lead.

I found this modification to be an improvement, as the LEDs are brighter and should last much longer. ■

Caution: Solid-State Finals

—learning to live with no-tune radios

Here you are—your brand new Mark XVIII Loudenputer unpacked, connected to the power supply, and your old tri-band beam plugged in. Key down; measure the power output—only 15 Watts instead of the rated 100 Watts. Check the instruction manual and notice that the power rating holds for a 50-Ohm load. You have been using the beam for five years with your old Heath or Swan without a matchbox so you know the antenna is OK. Guess you will have to send the new rig back for repair.

Before you go running down to the post office or UPS, perhaps you ought to take a second look. Your new rig has solid-state finals, and your old rig a pair of 6146s. There is a considerable difference.

Design Differences

A typical tube final is shown in Fig. 1(a). The tubes, which are the source of rf power, feed an adjustable network which matches the tube output impedance to the load. This load is not a 50-Ohm dummy load but a real-life antenna whose impedance may vary drastically with the operating frequency and with weather conditions such as wind and temperature.

The solid-state rig is shown in Fig. 1(b). A set of transistors feeds a fixed bandpass filter. This filter changes only as you switch bands. The key difference (and advertised advantage) is that no tuning is required. Just change bands, dial up the operating frequency, perhaps peak a preselector, and transmit. In fact, except for a desire to see what is going on, there is no apparent need for a collector current meter since there is no dipping or peaking required.

This basic design difference leads to what has been called the "A-OK into dummy load" syndrome. In the example given above, the rig probably puts out the full rated power when connected into a dummy load. With a practical antenna, however, low power, tripping breakers, or even self-destruction of the finals may result. More insidious is the potential for the generation of spurious signals due to antenna mismatch, even though the rig is perfectly clean (and has been type-accepted) when connected to a dummy load.

Why Does It Happen?

Solid-state amplifiers are designed as broadband amplifiers followed by a bandpass filter under the assumption that a purely resistive 50-Ohm load is connected to the output. If the amplifier is not connected to an ideal load, i.e., the load is not 50 Ohms resistive or contains reactive components, the bandpass filter is no longer terminated in its design conditions, and it may no longer act as the needed filter. In addition, the filter also is designed to be driven by a fixed source (the transistors), and if the transistors are operating at a higher or lower power level (Fig. 2), the filter is again not operating under its de-

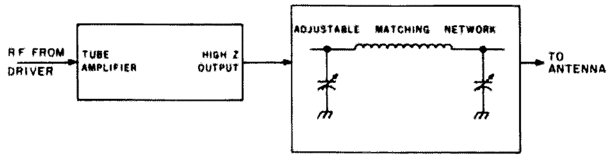

Fig. 1(a). A typical tube final.

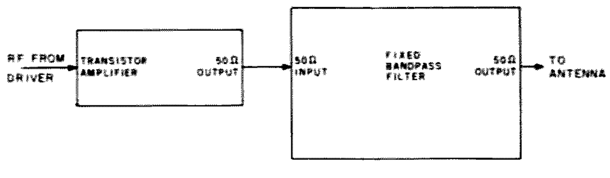

Fig. 1(b). A solid-state rig.

signed conditions. This leads to the remarkable situation in which some rigs may operate perfectly well when tuned up at full power but put out spurs if you try to operate at low power.

A number of rigs which have power-foldback protection suffer doubly from this effect. When connected to a moderate swr load (say, 3:1 or higher), the swr is sensed, and in order to protect the finals, the drive to the finals is now decreased. This means that the bandpass filter is no longer fed by transistors operating with the design output impedance and, in addition, the filter is connected to a load far different from the 50-Ohm design load.

What Choice Do You Have?

Since most if not all of the new rigs have solid-state finals, we have to live with the problem. There are, however, a number of things you can do to put out full power, protect your finals, and prevent spurs from occurring.

1) You probably will have to use an antenna tuner or matchbox. The disadvantage of having more knobs to turn is not that serious, since you no longer have to dip and peak your final. Caution: Tuning for minimum swr or maximum power output may not be enough. You may have to build or buy a noise bridge and preset the tuner on your favorite operating frequencies.

2) You may have to operate the rig near full power all the time. Run a test. If your swr varies drastically as you reduce the drive to your rig, you may be putting out spurs at the lower power levels. Similarly, don't overdrive it. The couple of extra Watts you get beyond the manufacturer's ratings may all be out of the band.

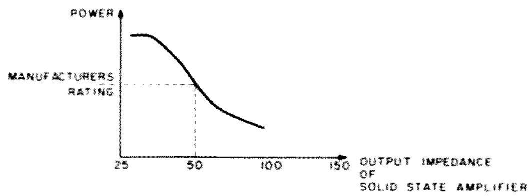

Fig. 2. Impedance change vs. power level.

3) Be careful in selecting a linear amplifier. Untuned inputs on grounded-grid linears may have been perfectly acceptable with vacuum-tube exciters. However, if your solid-state rig has power-foldback or some other protection and the linear does not have a 50-Ohm input impedance, you either might not be able to drive the linear to full power or you might have to use a matchbox between the rig and the linear.

4) Be careful (especially on VHF) of mating a rig to an amplifier. Tube equipment was tolerant. Transistors are not. If your new little handie-talkie does not have sufficient protection, the finals may vaporize in the time it takes the relay in the amplifier to switch. Be cautious and talk to someone who has seen this combination working before.

5) Read and reread the instruction manual. If you don't understand, or if information is not included, call the distributor or manufacturer. Users groups can be very helpful. There is no reason for you to guess how to use it when there are five thousand identical rigs being used. ■

Under Software Control

—a repeater control system with minimal hardware

This computer program, which runs on a MOS Technology KIM-1 microcomputer, will replace all the control circuitry normally required for a small repeater system. This system features a smart CW ID, a courtesy beep, remote control, time-out timer, and an ID interval timer, all implemented without any external hardware.

The KIM-1 microcomputer is an ideal system for this type of application, with its built-in I/O ports and interval timers; all the necessary hardware for undertaking this project is provided as an assembled and tested unit.

When it was decided to undertake this project, the highest priority was given to implementation with a

Location	Function
002D	Length of kerchunk delay
004F	Setting of time-out timer in minutes
00B0	Setting of ID interval in minutes
0283	CW speed
0284	CW tone
02C1	Space for breakers
02C6	Length of courtesy beep
02D3	Length of transmitter tail

Note: Changing the CW speed will affect all timing parameters, except the two clocks, in the same manner as the speed is changed.

Table 1. Program timing variables.

Ltr	Code	Ltr	Code	Ltr	Code

4	0C	5	04	6	84
7	C4	8	E4	9	F4
/	94				
Space	00				FF

End of Message

To program your repeater call, look up each letter of call in table above and put code into KIM starting at 0068; for a space between words, put a 00. Remember, at the end of the message, to put an FF in memory.

Table 2. ID code table.

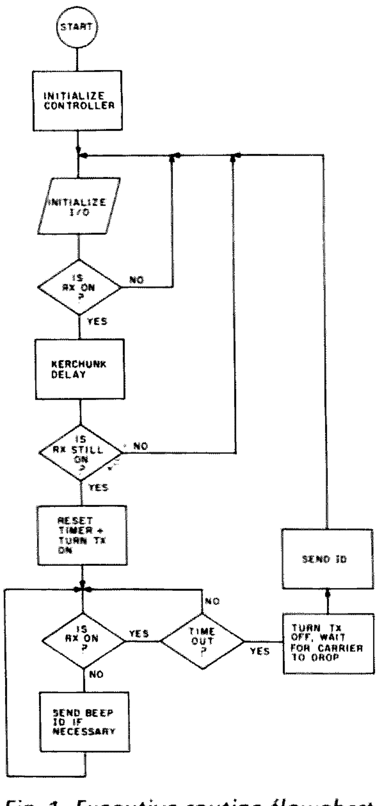

Fig. 1. Executive routine flowchart.

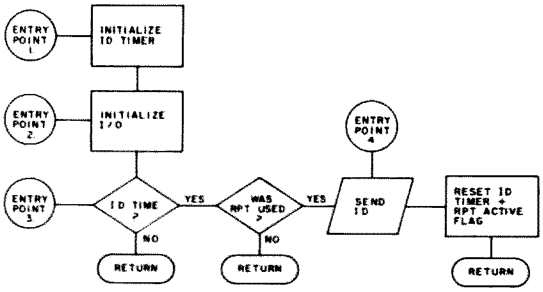

Fig. 2. Initialization routine flowchart.

minimum amount of support hardware and a maximum amount of work being done by the software. That goal has been successfully reached here without any compromises in the performance of this repeater control system.

The control system will send the required repeater ID in CW. The audio tone required is generated internally by the microprocessor. The repeater system, when not active, will ID only if the system has been keyed within the current ID interval; otherwise it will ID after the next keying. When the repeater is being used, it will ID only after the courtesy beep has been sent, minimizing the chance of the IDer's audio covering a user's transmission through the repeater. The ID interval is currently set at 7 minutes, but the control system can be set at from 1 to 60 minutes in one-minute intervals.

If the repeater is timed out by a signal staying on too long on the input frequency, when the signal is removed, the system will immediately ID, informing the user that he timed the repeater out. The time-out interval is currently set at 3 minutes; this can be set at rom 1 to 60 minutes in one-minute intervals.

Two interrupt-driven real-time clocks have been implemented in software using one of the KIM-1's rogrammable interval imers. The other programmable interval timer is used to generate the required audio tones.

A kerchunk filter has also been added which prevents the repeater from being keyed by a signal on the input frequency of the repeater for less than one second in duration. This kerchunk filter does not affect the operation of the repeater once it has been activated.

A remote-control feature has also been provided for in this control system to turn the repeater on and off when this is necessary.

The program provided here has all of the timing parameters set for a very pleasing sound on the air. Almost every timing parameter in the controller program can be changed very easily, however, should you desire to change it. Table 1 shows all of the important locations that can be changed and what effect they will have on system operation.

Figs. 1 through 6 are the flowcharts for the program modules which comprise this system. These flowcharts, combined with the freely-commented program listing, should make the understanding and modification of this control system relatively easy.

The flowchart for the executive routine is shown in Fig. 1. The starting location for this routine is at 0000, and this also is the entry point for activating the control system. The executive routine is where this system spends most of its time. It is this routine which provides the logic for how the repeater will respond to an incoming signal. Any lines of the program that need to be used frequently have been coded as subroutines. The time-out routine is located in the executive routine, as is the kerchunk filter. The executive routine and the courtesy-tone routine together determine when to ID.

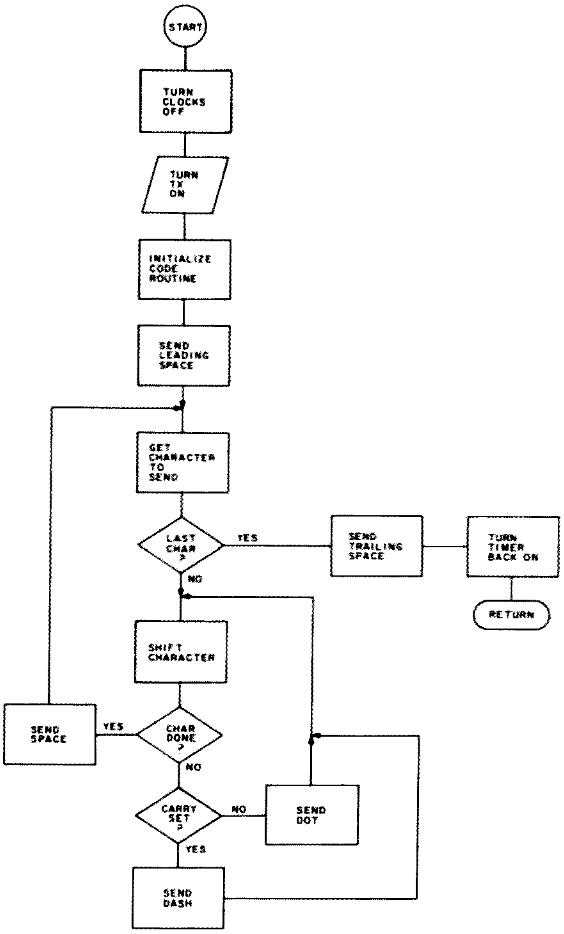

Fig. 3. CW ID routine flowchart.

After the executive routine, next in memory is the code for the CW ID. The ID must start at location 0068 and must not exceed location 007F. Table 2 gives all the information needed to program your own callsign into the system.

The next subroutine we come upon is the receiver mask routine. No flowchart is provided because of its small size and simple coding. This is where the system determines if the repeater's receiver is being activated.

The initialization routine, a flowchart of which is shown in Fig. 2, starts at location 009A. This routine handles all of the input and output port initialization and control of the CW IDer. There actually are four entry points to this subroutine; they all are labeled in the program listing along with their use.

The subroutine for sending the CW ID is located starting at 0200. The flowchart for this routine is shown in Fig. 3. This routine is a much-modified version of a program published in

Program listing.

the *First Book of KIM*.* This program now has the ability to take strings of code directly from memory and send them out as CW and the ability to insert spaces between words and indicate the end of the message. In addition, the portions of this module which actually generate the audio tones have been changed to use the programmable interval timer normally used by the KIM-1's cassette I/O routine. This change freed up the other interval timer which can be used to interrupt-drive another program. This timer is then used in the real-time clock subroutine. Subroutine calls are made frequently to routines in this module to handle various timing delays and to generate the courtesy beep.

The courtesy-tone routine which starts at location 02C0 is shown in the flowchart in Fig. 4. The length of the time allotted for breakers before the courtesy beep, the duration of the courtesy beep, and the length of the repeater's transmitter tail are all controlled in this routine. All the timing for these functions can be changed in this routine, if desired. When the repeater system is in use, this subroutine calls the CW ID module.

The flowchart for the real-time clock routine is shown in Fig. 5. This routine is a continually-running interrupt-driven clock, driven by the NMI interrupt vector. This routine is a much-modified version of another program which appeared in the *First Book of KIM*. This real-time clock routine con-

tains two independently running real-time clocks, each of which is capable of keeping time from 0 seconds to 1 hour and then resetting. These two timers comprise the ID interval timer and the time-out timer.

Immediately following the real-time clock routine is the remote-control routine. The flowchart for this routine is shown in Fig. 6. This routine is entered after the computer receives a request for an interrupt from the IRQ interrupt line on the KIM-1. To take the repeater off the air, all you need to do is to have your remote control circuitry give a logic 0 pulse to the IRQ line. The remote-control routine will then put the program in a tight loop, not allowing the repeater to be activated. To turn the repeater back on, your control circuitry must apply a logic 0 to PB0 of the KIM and a logic 0 pulse to the IRQ interrupt line. The control system will then exit the tight loop and restart the control program. The repeater will immediately come on the air with the CW ID. This routine might seem overly simple to some, but it gets the job done quite nicely.

The last subroutine is the three-minute time-reset routine. This routine has not been flowcharted because of its simplicity. The only function of this routine is to reset the three-minute timer upon initial repeater key-up and after the courtesy beep.

If you look at the program listing, you will notice that all of page 1 in the KIM-1 memory is empty. At present, this area is available entirely to the stack. All of this space is not needed for the stack, and the

lower portion of page 1 is available for future expansion.

In order to use this control system in your repeater, a word is in order about connecting to the KIM-1 and interfacing into the receiver and transmitter. First, the NMI interrupt line (pin 6, KIM-1 expansion connector) should be connected to PB7 (pin 15, KIM-1 application connector). This will allow the real-time clocks to function.

Next, PA0 (pin 14, KIM-1 application connector) should be connected to the repeater's transmit audio, as this line will have the CW tones on it. The next line that you need to hook up is the transmitter keying line. This line is PA2 (pin 3, KIM-1 application connector). This line provides a logic 1 when the transmitter is supposed to be on. You will have to interface this to turn your transmitter on.

This connection cannot be a direct one as a KIM-1 I/O pin will sink only about 1 mA of current. In the repeater I used to develop this controller, my transmitter was solid state and drew 15 mA to ground to key the transmitter. A buffer IC was connected to PA2 and this was sufficient to sink the 15 mA directly. Depending on the type of transmitter you are using, you may need to have a buffer IC drive a transistor or even a buffer IC to drive a transistor and have the transistor drive a relay to operate your transmitter.

Next, you need to connect a COR output from your repeater's receiver to PB5 (pin 16, KIM-1 application connector). Your COR output must be a logic 0 when receiving a signal. When the receiver is squelched, the voltage on the COR output line going to the computer should be less than 5.5 V to prevent possible damage to the computer. In my system, using a transistorized receiver, I hooked up a COS (carrier-operated switch) to the receiver and connected that transistor directly to PB5. In order for this system to work, the grounds of this controller, any interface circuitry, the receiver, and the transmitter should be connected together—no floating grounds are allowed. Also, the power line to the computer should be as well filtered as possible.

If you are using the remote-control portion of this control system, then you also must connect PB0 (pin 9, KIM-1 application connector) and IRQ (pin 4, KIM-1 expansion connector) to the appropriate points of your control circuitry. The last thing you need to do before putting this system on the air is to put a CW ID into the controller. This is explained in Table 2 and you can use the example in the program listing for DE WD8CHH/RPT CLE as further help.

This control system has been exhaustively tested and all of the bugs should be out by now. However, if you have a problem, contact me and I will provide whatever assistance I can. ■

The Fun-Mitter— A Goof-Proof Rf Project

—fail-safe QRP rig uses Radio Shack parts

The purpose of this project was to build a simple transmitter that could be duplicated easily by any amateur.

My main interest as an amateur lies in designing and building my own equipment. During numerous on-the-air conversations, I discovered that home-brewing is not a forgotten art and that many hams are still interested in building at least some piece of equipment for use in the shack. However, it seems that a good portion of newcomers (and not-so-newcomers) are frustrated when trying to find a project that is simple enough to understand, is cheap, and will produce a useful item which is not time-consuming to build, debug, and get operational.

This 5-Watt, 80/40-meter, CW transmitter is all of this and more. All of the parts can be purchased at your local Radio Shack, assembly time is less than an hour, and tune-up time is zero. Using a PC board practically guarantees that the transmitter will work the first time the key is closed. These features should make this a project that both the Novice and old-timer can enjoy.

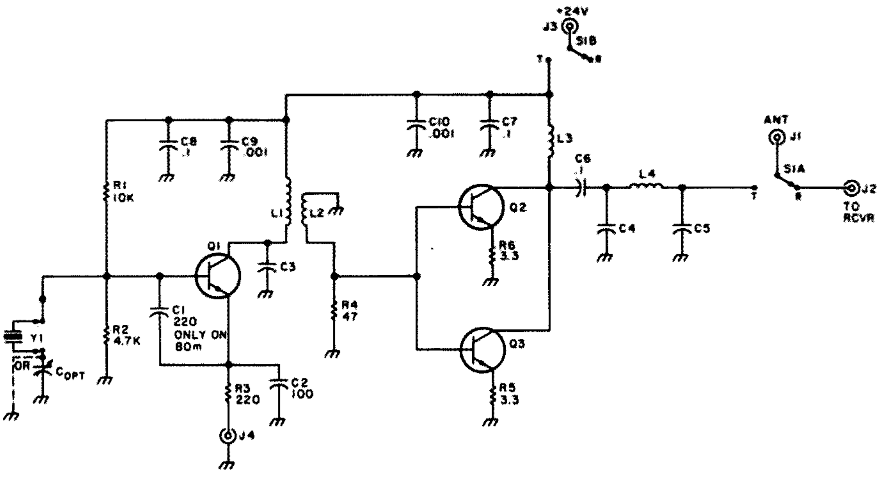

Fig. 1. Transmitter schematic.

My original design called for vfo control of the transmitter, but that required five rather than three transistors. Additionally and more importantly, the components needed to construct a stable vfo cannot be purchased at most Radio Shack outlets. To overcome these problems, crystal control was decided upon. At first thought, crystals conjure up an image of hours of operating without a contact as you wait for someone to happen upon your frequency. That simply isn't the case, as will be shown later. Also, since Novices now can use vfos, there are many crystals lying around in ham shacks everywhere.

The transmitter can be built as a basic unit or with

several options, as shown. The basic unit consists of the loaded PC board soldered to an antenna connector and power source. If the transmitter is to be used for serious operation—which it definitely is capable of—then the options, which require only a little more time and money, should be added. Options will allow T-R switching, some frequency variation, two bands in one box, and a package that is more pleasant to look at and show off.

Photo A. Completed transmitter.

The Circuit

As can be seen from Fig. 1, the transmitter meets the design goal of being simple. Only three transistors are used to generate the 5 Watts of output power. Resonant circuit inductors are formed using iron-core rf chokes. Common-value ceramic capacitors are used either singly or in parallel to obtain the needed capacitance.

Q1 operates as a Pierce oscillator at the crystal frequency. FT-243 crystals, which are inexpensive and plentiful, can be used. Output is taken from Q1 by a five-turn link over L1. Q2 and Q3 comprise the class C final amplifier and are operated in parallel. Parallel operation provides an easy method of obtaining the desired 5-Watt output.

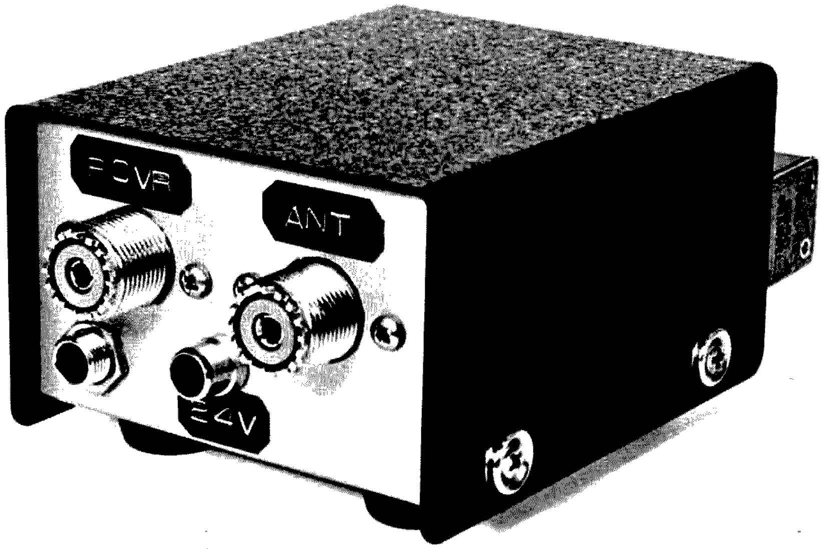

Photo B. Back view.

The parallel combination of Q2 and Q3 presents about a 60-Ohm load to be matched to the 50-Ohm antenna load. This collector impedance is determined from the formula $RL = Vcc^2/2po$, where $Vcc = 24$ V and $po = 5$ Watts.

The impedance transformation is accomplished with a pi-network composed of L4, C4, and C5. This network also offers harmonic attenuation to the signal. The transmitter, as designed, easily meets the FCC regulations for harmonic radiation.

R5 and R6 are used to equalize current flow in the two transistors. In all of the units built thus far, I have detected no "hogging" of current by either transistor. Nothing special has been done in selecting matched transistors. If they run equally hot, they are matched well enough! Heat sinks are needed on both transistors to dissipate the heat generated. Since the type of heat sink needed is not available at Radio

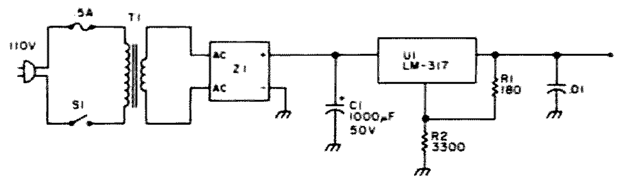

Fig. 2. Power supply schematic.

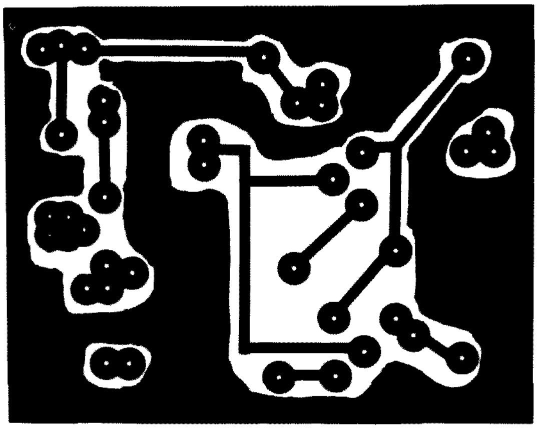

Fig. 3. PC board layout, foil side. (Single-sided, fiberglass, copper-clad board.)

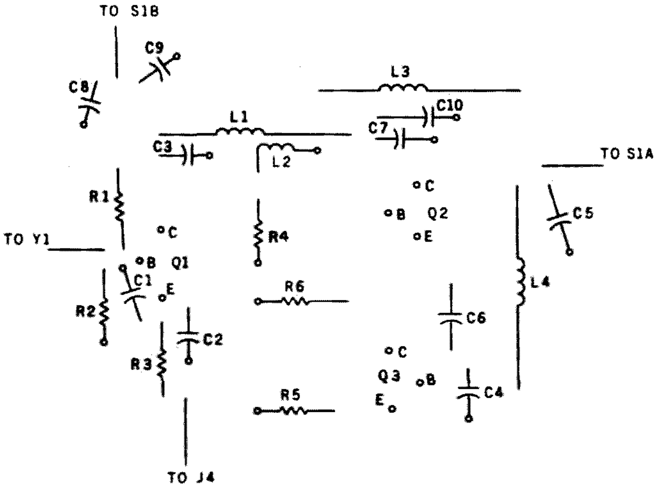

Fig. 4. Component locations.

Shack, they must be constructed by hand. Light gauge aluminum can be used by forming a tightly fitting cap over the transistor.

The design goal of using readily-available parts was realized throughout the rig. Radio Shack disc ceramic capacitors are used and have performed well. Unfortunately, there is a limited variety of these parts. To obtain the desired capacitance, the capacitors, where necessary, are soldered in parallel. This allows for the elimination of variable capacitors to tweak the tuned circuits to resonance. In all units assembled, the resonant circuits and matching networks have worked fine with no tweaking necessary.

To construct L1, remove the required number of turns from the Radio Shack

choke. Use this removed wire to form the link winding, L2. Wind L2 over the Q1 side of L1. L3 should be made similarly except that no link is needed. The chokes work surprisingly well as resonant circuit inductors at 3.5 and 7 MHz.

One departure from the norm in this project was the use of +24 V for supply voltage rather than the more common 12 volts. This was done for several reasons. It is much easier to build and get operational a 24-volt supply than it is the additional stages required to realize 5-Watts output using a 12-V supply. This also makes the transmitter simpler and cheaper (other design goals).

A schematic for a very simple 24-V supply is shown in Fig. 2. This supply can be made variable or fixed. It has performed flawlessly at currents up to 1.5 Amps. The regulator contains internal short-circuit protection and is self-contained.

If an ac-operated supply is not desired, four 6-V lantern batteries can be operated in series to provide the needed 24 volts. Many hours of transmitter operation can be achieved from such batteries. Alternatively, and probably cheaper, sixteen D-cells can be soldered in series for the supply voltage. Obviously, the 24-volt supply should not be a deterrent to building the transmitter. It can be used for later projects as well!

Construction

The transmitter is built on a 2¼" by 3" PC board. Assembly time is less than one hour due to the small number of parts used. A number of transmitter boards have been constructed and each one has worked fine when power was applied.

For best operating comfort, the transmitter PC board should be mounted in an enclosure—as mentioned earlier. Any size or type of enclosure will work fine. I used a Radio Shack type, which makes for a nice-looking and compact transmitter.

A crystal socket should be mounted on the front panel to allow for a change of frequency when desired. A variable capacitor can be mounted near the socket to allow for a small amount of frequency excursion from the crystal frequency. On 80 meters, about 1.5 kHz of change has been possible. On 40 meters, this increases

to about 3-5 kHz. The amount of frequency excursion will vary, depending mostly upon the crystal used.

Switch S1, a miniature DPDT toggle type, is used to switch the antenna between receive and transmit. All connections between S1, the PC board, and the SO-239 antenna connectors should be made with coax. RG-174 is preferred, but if it is not available, RG-58 will work fine. The only other additions necessary are a phono connector for voltage and a key jack.

If desired, the 40-meter PC board can be mounted in the same box as the 80-meter board to make a two-band transmitter. Another toggle switch will be needed to switch the two boards to the appropriate circuit points.

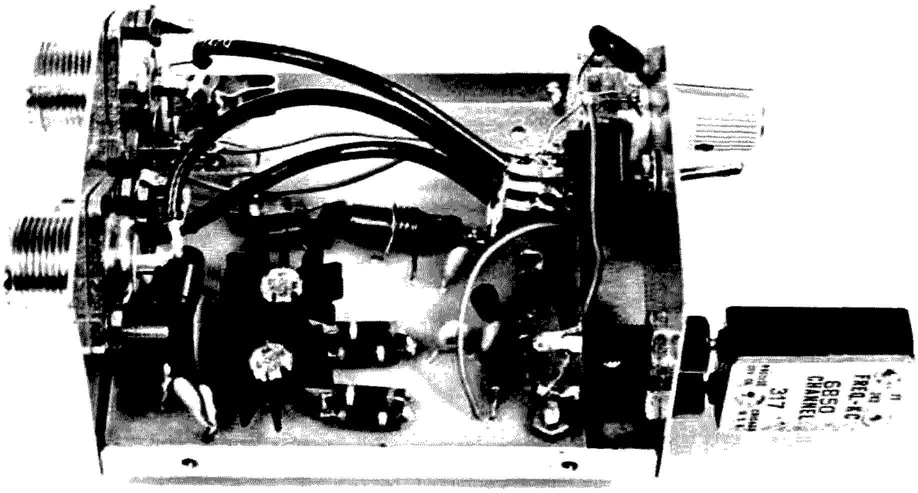

Photo C. Inside view.

Operation

After assembling the PC board and the supporting parts into a cabinet, the transmitter is ready for use. Initially, a dummy load should be connected to the antenna connector. This allows for testing without generating QRM on the air. The dummy load can consist of two 100-Ohm, 2-Watt resistors in parallel. If a VOM (ammeter) is available, it might prove advantageous to hook it in series with the plus side of the 24-V supply. Input power can then be calculated.

After the key is plugged in, the supply turned on, and the crystal installed, switch S1 to transmit and close the key. The VOM should read about 350 mA of current. This indicates an input power of approximately 8.5 Watts (Pi = E × I = 24 × .35). All of the transmitters I have built have had a minimum efficiency (Po/Pi) of around 60 %. This indicates an output power of around 5 Watts. The input (and output) power of your transmitter might vary depending upon the gain of the transistors used.

An antenna now can be hooked to the SO-239 antenna connector. At the same time, a short cable should be run between the receiver-out connector and your receiver.

You are ready now for on-the-air contacts. You probably will be as surprised as I was when you first use your new little powerhouse. Surprisingly, my best success has been in calling CQ. The response ratio has been close to 50%. Using one crystal on 80 meters has resulted in numerous contacts up to 1500 miles away with excellent reports in both strength and quality. The antenna used in conjunction with the transmitter has been a dipole at 20 feet.

Conclusion

The transmitter has met the objectives I set out to achieve. It has been fun to design, build, and to use. Hopefully, this article will encourage you to try to build some type of homebrew gear. A simple receiver board can be constructed easily and in-cluded with the transmitter. Such a receiver is currently being designed. Good luck in home-brewing! ■

LOOKING WEST

from page 14

great deal of time experimenting with antenna systems for VHF and HF. Bob designed and built one of the nation's most exotic repeater systems: WD9GOE, located in his hometown of Marissa, Illinois, some 70 miles outside St. Louis. He also spearheaded the now-annual ARCH Convention in St. Louis and has accomplished so much in his life that it could fill many volumes.

Bob's book is covered in the Review section of this issue of *73 Magazine*.

THE VOCOM ANTENNA DEPT.

Elsewhere in Illinois there exists a company that calls itself VoCom, and they have a rather interesting product. It's a 5/8-wave gain antenna that collapses to 8" and is designed to be used directly on a hand-held fitted with a BNC-type connector. I became interested in this product after moving to our new home. (One thing to mention on my new home: While set in a beautiful canyon, I actually purchased a $70,000 "dead spot" that came complete with "CC & Rs" which prohibit any outside antenna structure. Not that the latter would be of any distinct advantage over what I have in the attic, unless I erected a tower some 650 feet high. I knew what I was getting into when I bought the place and do not regret the move. I bank heavily on a remote-base system atop a nearby peak to keep in touch with the outside world.)

But now and again it's nice just to chew the fat simplex (direct), and my Wilson Mark II is just the ticket at those times. With the supplied rubber ducky, I found my simplex range to be under a mile. I tried a ¼-wave whip and got another mile out of that. In fact, with the ¼-wave, I could be heard through the nearby WR6AHM Magic Mountain repeater. Barely, I grant you, but readable. The Icom 22 and attic-mounted, 4-element beam put me in solidly, but are not convenient when one wants to lie in bed for a chat.

Anyhow, through a friend I heard about the VoCom antenna and procured one. I was very skeptical when it arrived. Taking it out of its shipping container, I found what appeared to be a TV rabbit ear antenna rod designed for an early model Sony TV, mated through a covered coil to a BNC plug. I was not all that impressed.

"Oh, well. What the heck. Let's give it a try," I said to myself. I tried keying up Magic with the ducky so that I would have a basis for comparison. As usual, there was no way to key up Magic with the ducky. Then I substituted the VoCom, extended it out to its full 47 inches and tried again. "You're full quieting, Bill. You using the beam?" was the first report. I was astounded. No way, I thought. I had the station stand by and tried the ducky. No luck. Back on the VoCom I was DFQ. "The bloomin' thing works!" I thought to myself.

Subsequent QSOs on 146.52 have proven to me that the manufacturer's performance claims are in the ballpark (which is something else rare in this age of hype and jive). Last night, under normal conditions, I completed a QSO with a station in the Simi Valley some 45 miles away. Signals were fair both ways. One of these days I'll publish a photo of these surroundings to show the terrain I am up against. If this antenna will work here, I think I can safely say that it will work anywhere. The VoCom HT Gain Antenna is available for $24.95 from VoCom, 65 E. Prospect, Suite 111, Prospect Heights IL 60070. In my opinion, it's worth the asking price and then some.

VOYAGER AND ATV DEPARTMENT

One of the most fascinating places in Southern California is the Jet Propulsion Laboratory in Pasadena. For well over a decade, JPL has been the scene of some of the greatest breakthroughs in the history of man's conquest of the "final frontier." Many of us grew up watching the epic of American space exploration unfold through the eyes of news correspondents and scientists in press conferences.

Saturn and its satellites Tethys (outer left), Enceladus (inner left), and Mimas (right of rings) are seen in this mosaic of images taken by NASA's Voyager 1 on October 30, 1980, from a distance of 18 million kilometers (11 million miles). The soft, velvety appearance of the low-contrast banded structure and increased reflection of blue light near the perimeter of the Saturn disk are due to scattering by a haze layer above the planet's cloud deck. Features larger than 350 kilometers (220 miles) are visible. The projected width of the rings at the center of the disk is 10,000 kilometers (6,000 miles), which provides a scale for estimating feature sizes on the image. Photo courtesy of NASA.

In November of 1980, we witnessed another chapter in this ongoing story as *Voyager 1* had a "Close Encounter of a Special Kind" with the planet Saturn. We saw the close-up photos of Saturn, its rings and its moons, in a manner never seen before. For all the questions answered by the *Voyager 1* flyby, new ones arose. We watched as *Voyager*, a billion miles off in endless space, performed its appointed task flawlessly, sending back television photos of the ringed world. From the comfort of our own homes, we watched as people such as NBC's Roy Neal brought these pictures to us via our own TV set. Together we lived through another great moment in man's conquest of the unknown.

Among the first to see some of these epic photos were those of us who are amateur radio operators. This because there exists at JPL one of the nation's most active amateur radio clubs, an organization well known for doing its part to help commemorate events such as this. In the past, whenever a close encounter such as this took place, the JPL Amateur Radio Club went on the air sending slow-scan photos and offering commemorative QSL cards which have become collectors' items. The *Voyager 1* Saturn flyby was no exception, as those of you who QSOed W6VIO (*Voyager* in Outerspace) during this time period are well aware. For the better part of November, W6VIO was operational on a daily basis. Hot from the JPL imaging department, photos were aired on various amateur bands worldwide, using slow-scan television techniques. But that was not all. For the *Voyager 1*

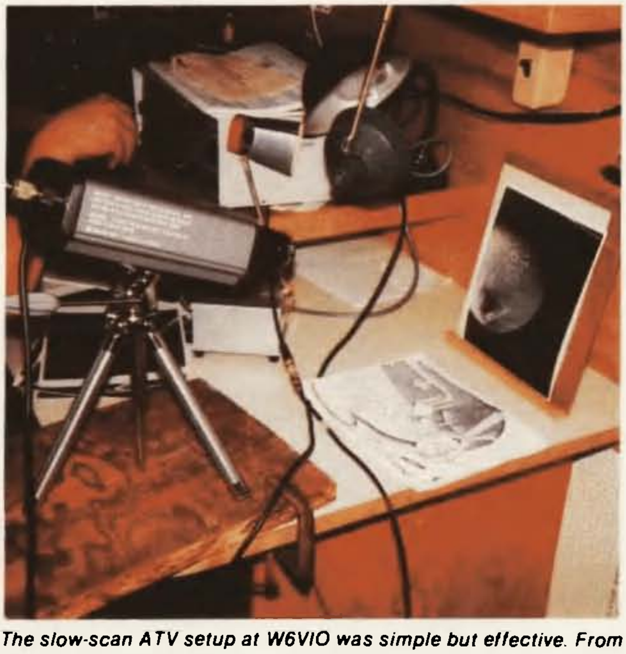
One of the visitors to W6VIO during the Saturn encounter was Mike Davis WD6FFV. Many of you will remember Mike. Two years ago, at age 13, he coordinated the rescue of three people aboard a sinking boat in the Caribbean.

Those JPL employees operating at W6VIO did so on their own time. These two manned the 220-FM position and ate lunch at the same time. Talk about dedication!

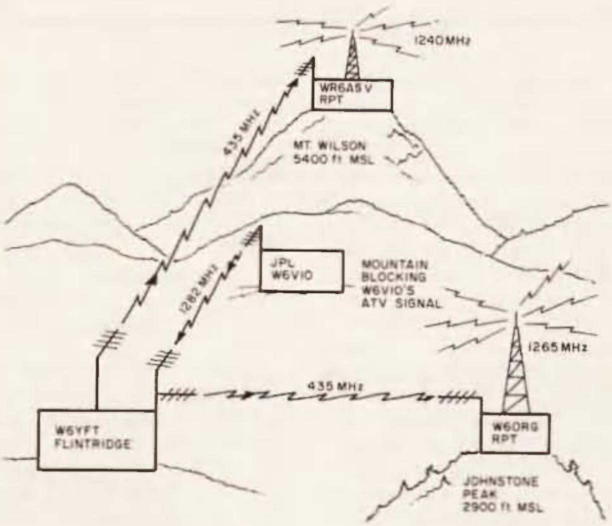
Saturn encounter another dimension was added: regional fast-scan television using facilities provided by Tom O'Hara W6ORG of P.C. Electronics and the Southern California ATV Club.

The fast-scan installation was rather unique. The idea was to get the video signals from W6VIO into two area ATV repeaters, one located on Johnstone Peak near Pomona, California, and the other on Mt. Wilson. As you can see from the accompanying pictorial, while JPL may lie in the shadow of Mt. Wilson, it is not line-of-sight to it. JPL also is effectively blocked from Johnstone Peak by other hills. One of the places it could see easily, however, was the Flintridge area, so a decision was made to install an intermediary link at the home of Dr. Dale Hauck W6YFT. Television was then generated at W6VIO, relayed to W6YFT and into the two crossband ATV repeaters, affording the ever-growing ATV community out here a chance to see things first hand.

The fast-scan operation was every bit as successful as was the slow-scan. There were reports of reception as far away as Riverside and San Diego, and it was of good quality color photos many times accompanied by descriptive audio of what was being seen. The fast-scan was so well received that plans already are being made to repeat the setup next summer when *Voyager 2* encounters the ringed planet and scientists again try to unravel some of the mysteries of space. In the meantime, if you were among those fortunate enough to QSO W6VIO, I urge you to send for one of their QSL cards. Be sure you are a "logged contact," and send your own QSL confirming the contact along with a #10 self-addressed, stamped envelope to W6VIO at their *Callbook* address. When you receive yours, you might want to frame it. Not only to protect it, but so that it will stand out among the rest as a symbol of your personal participation in a rather monumental achievement of mankind.



The slow-scan ATV setup at W6VIO was simple but effective. From this position, pictures were seen worldwide.



CONTESTS

from page 19

Work as many QCWA members as possible and apply for the several Special QCWA Certificates which you have qualified for in the QCWA Parties: Worked 50 States, Worked 60 Chapters, Worked 100 Members, and Worked 500 Members.

ARRL INTERNATIONAL DX CONTEST—CW

0000 GMT February 21
2400 GMT February 22

The ARRL-sponsored contest is open to all amateurs worldwide. Note that the basic contest format has been returned to that of 1979, with W/VE stations working the world and everybody else working W/VE stations only. The changes to single-band categories and the expanded awards program proved very popular and remain unchanged. Use all bands, 1.8 to 30 MHz.

Operating categories include: single operator allband and single-band, multi-operator single transmitter or multi-transmitter, QRP single transmitter only with 10 Watts input or less (5 Watts output or less).

Your callsign *must* indicate your DXCC country (KL7XYZ/2 in NJ, FG0AAA/FS on St. Martin, etc.). One operator may not use more than one callsign from any given location during the contest period. The same station may be worked only once per band. No crossmode, crossband, or repeater contacts. Aeronautical and maritime mobile stations outside the USA and Canada may be worked for QSO credit only by W/VE stations. All transmitters and receivers must be located within a 500-meter diameter circle, excluding directly-connected antennas. This prohibits the use of remote receiving installations. However, multi-operator stations may use spotting nets for multiplier hunting only.

EXCHANGE:

W/VE stations (includes 48 contiguous United States and does *not* include Canadian islands of St. Paul and Sable) send RST and state/province. DX stations send RST and transmitting power as a 3-digit number.

SCORING:

W/VE stations count 3 points per DX QSO. The multiplier is the sum of DXCC countries (except US and Canada) worked per band. DX stations score 3 points per W/VE QSO. The multiplier is the US states (except KL7 and KH6), VE1-7, VO, and VE8/VY1 worked per band. Maximum of 57 per band. Final score is total QSO points times the total multiplier.

AWARDS:

Various plaques and certificates to top scorers. Certificates to each DX entrant making more than 500 QSOs. ARRL affiliated clubs compete for gavels on three levels: unlimited, medium, and local clubs. Details should have appeared in the January, 1981, *QST*.

ENTRIES:

All entrants are encouraged to use forms available from ARRL (include an SASE or one IRC). Logs should indicate times in GMT, bands, calls, and exchanges. Multipliers should be clearly marked in the log the first time worked. Entries with more than 500 QSOs must include cross-check sheets. All operators of multi-operator stations must be listed. Entries must be postmarked by April 7, 1981, and addressed to: ARRL, 225 Main Street, Newington CT 06111. Any entries received after mid-July may not make *QST* listings. Usual entry conditions and disqualification criteria.

G-QRP-CLUB
CW ACTIVITY WEEKENDS

0900 GMT February 28
2300 GMT March 1
0900 GMT September 12
2300 GMT September 13

All amateur radio amateurs interested in QRP are invited to take part in the club's activity weekends. No special exchange information was mentioned in the information provided by the club. The operating schedule for the two weekends is as follows:

3560 kHz = 0900-1000, 1700-1800, and 2200-2300 GMT
7030 kHz = 1200-1300, 1500-1600, and 1900-2000 GMT
14060 kHz = 1000-1100, 1400-1500, and 2100-2200 GMT
21060/28060 = 1100-1200, 1600-1700, and 2000-2100 GMT

Reports on the Activity Weekends are welcomed by Christopher J. Page G4BUE.

In addition to the above, members of the G-QRP-Club have a weekly Activity Period on Sundays from 1100-1230 and from 1400-1530 GMT on the International QRP frequencies (3560, 7030, 14060, 21060, and 28060). All radio amateurs interested in QRP are invited to join in.

For information regarding membership in the G-QRP-Club, write: George Dobbs G3RJV, 17 Aspen Drive, Chelmsley Wood, Birmingham, England B37 7QX. The club publishes a quarterly magazine called *SPRAT* and promotes an extensive awards program for QRP achievements.

HAM HELP

We are happy to provide Ham Help listings free, on a space-available basis. We are not happy when we have to take time away from other duties to decipher cryptic notes scrawled illegibly on dog-eared post cards and odd-sized scraps of paper. Please type or print (neatly!), double spaced, your request on an 8½" × 11" sheet of paper and use upper- and lowercase letters where appropriate. Also, please make a "1" look like a "1," not an "l," which could be an "el" or an "eye," and so on. Hard as it may be to believe, we are not familiar with every piece of equipment manufactured on Earth for the last 50 years! Thanks for your cooperation.

I need information on using a solid-state oscillator in HBR receivers by Ted Crosby. I will answer and send postage. Thanks.

Owen Laughlin KA8CXK
719 Hemphill
Ypsilanti MI 48197

I need a working charger for the Motorola HT-220 transceiver. I am a senior citizen ham, so I need a low price, please.

Bob Clark W5BTZ
8260 Wateka Road
Richardson TX 75080

I need a copy of the manual for the Gonset GSB-201—an original or photocopy would be OK. I'll be happy to pay for all costs.

Steven Bein K6MBP
3044 Danalda Dr.
Los Angeles CA 90064

I have a Hammarlund Super Pro receiver, military no. BC-779-B. It does not cover 10 or 15 meters, which I would like to have. It has one band marked 100-200 KC and the other, 200-400 KC. There was a conversion kit but the company no longer has them.

If anyone has a conversion kit for this receiver or a BC-794-B or BC-1004 C, even though it doesn't work, and if the price is right, I would like to get it.

Donald B. Watkins
428 Oak St.
Warren AR 71671

I need a schematic and/or manual for a keyboard having the following markings: #2815051-01A. Unit has 91 keys and PC board has LICON 80-55157CS1-1 on it. It may have been used in a UNIVAC system. I will reimburse copying cost, will copy and return promptly, or purchase manual.

John Zowtiak N7BFX
750 Little Matterhorn Dr.
Salt Lake City UT 84107

Where can I get a replacement cabinet back for my Hallicrafters Model S38-B shortwave receiver? Mine was damaged and I've been unable to get a replacement from Hallicrafters. There must be distributors somewhere that have some of these and would be glad to sell them.

Duerson Prewitt K4ZCD
129 N. Maysville St.
Mt. Sterling KY 40353

W2NSD/1
NEVER SAY DIE
editorial by Wayne Green

from page 11

The crowding of Tokyo has forced much of the growth to go underground. This is a small part of the four-floor shopping complex which is involved with the Sunshine Prince hotel, where we stayed. There are two McDonalds restaurants in this one complex! There is also an almost infinite number of other restaurants, running from snack bars to very posh eateries. Multilayered underground shopping malls are growing rapidly in Tokyo.

Hmmm, octopus chips! Well, much better than cow chips, anyway . . . and free!

This is one of the Golden Arches attached to the hotel. It was a handy place to get milk. Not being a big Coke fan, I didn't pursue the nickel Coke offer. I did invest in their egg McMuffin for breakfast now and then.

Obviously, eating is an all-consuming interest for me. Here's a typical department store basement with its hundreds of food concessions. The happy innocents running these booths put out free samples to attract business. They also attract frugal Yankees, who are able to make a whole meal out of the samples.

Here's one of the food displays. The tempura jumbo shrimp are $7.50.

The subway system is easy to use, though it takes guts to try it the first time. You get the hang of it quickly. It's clean, fast, and well marked.

Each station is marked in both Japanese and English, with the stations at the ends of the line indicated so you know which train to take.

Yep, ice cream, too. The sundae prices are a bit high, but not out of line with the New York prices at $3 for the big banana split. Soft ice cream cones are usually around 75¢ and are sold all over the place.

You like grapes? Here are boxes of grapes... absolutely delicious grapes. The green ones are $20 a box and the smaller box of purple grapes is only $12.50.

To help dispel the idea that eating in Japan is expensive, here is a picture of a musk melon. This is a typical fruit product that I saw in dozens of fruit stores and fruit counters in department stores. To translate the Yen into dollars divide by 200. Thus, this melon is a mere $50 in American money.

In the Akihabara (radio row) section of Tokyo, there are hundreds of shops selling radios, parts, hi-fi, computers... everything in consumer electronics. With a bit of shopping, you can knock around 35% or so off the US prices, so I loaded up with new gadgets from Casio and Sharp. That's Sherry looking over the cassette bargains.

SOCIAL EVENTS

Listings in this column are provided free of charge on a space-available basis. The following information should be included in every announcement: sponsor, event, date, time, place, city, state, admission charge (if any), features, talk-in frequencies, and the name of whom to contact for further information. Announcements must be received two months prior to the month in which the event takes place. They should be sent directly to Editorial Offices, 73 Magazine, Pine Street, Peterborough NH 03458, Attn: Social Events.

MIAMI FL
FEB 7-8

The 21st annual Tropical Hamboree and 1981 ARRL Florida State Convention will be held on February 7-8, 1981, at the Flagler Dog Track, Miami FL. Registration is $3.00 in advance and $4.00 at the door. Swap tables are an additional $12.00 for both days, $7.00 for Saturday only, and $6.00 for Sunday only. Events will include tech talks and forums, over 100 exhibit booths, 400 swap tables, ladies' programs, group meetings, and many awards. There will be free overnight RV parking for self-contained units at the site (advance registration is recommended). Special gatherings are planned for QCWA/OOTC/SOWP and DXers. For further information and special hotel rates, write Dade Radio Club, PO Box 350045 Riverside Station, Miami FL 33135.

MANSFIELD OH
FEB 15

The Mansfield midwinter hamfest auction will be held on February 15, 1981, at the Richland County Fairgrounds, Mansfield OH. Doors will open to the public at 8:00 am. Tickets are $1.50 in advance and $2.00 at the door. Features will include prizes, an auction, and a flea market, all in a large heated building. Talk-in on 146.34/.94. For additional information, advance tickets, and/or tables, send an SASE to Harry Frietchen K8HF, 120 Homewood Road, Mansfield OH 44906, or phone (419)-529-2801.

FAYETTEVILLE WV
FEB 15

The Plateau Amateur Radio Association will hold Its 3rd annual hamfest on Sunday, February 15, 1981, at the Memorial Building, Fayetteville WV. The doors will open at 9:00 am and admission is $2.50, with children admitted free. Flea market tables are $2.00. Activities (all indoors) will include ARRL displays, forums, exhibits, door prizes, and XYL programs. Hot food, refreshments, and free parking will be available. Talk-in on 146.52 and 146.19/.79. For more Information, contact Bill Wilson WA8YTM, 302 Central Avenue, Apartment #2, Oak Hill WV 25901, or phone (304)-469-9910 or (304)-574-1176.

VERO BEACH FL
FEB 21-22

The Treasure Coast Hamfest will be held on February 21-22, 1981, at the Vero Beach Community Center. Admission is $3.00 per family, in advance, and $4.00 at the door. Features will include prizes, drawings, and a QCWA luncheon. Talk-in on 146.13/.73, 146.52/.52, 146.04/.64, and 222.34/223.94. For information, write PO Box 3088, Beach Station, Vero Beach FL 32960.

LIVONIA MI
FEB 22

The Livonia Amateur Radio Club will hold its 11th annual LARC Swap 'n Shop on Sunday, February 22, 1981, from 8:00 am to 4:00 pm, at Churchill High School, Livonia MI. There will be plenty of tables available. Other features include door prizes, refreshments, and free parking. Talk-in on 146.52. For further information, send an SASBE (4" × 9") to Neil Coffin WA8GWL, c/o Livonia Amateur Radio Club, PO Box 2111, Livonia MI 48150.

AKRON OH
FEB 22

The Cuyahoga Falls Amateur Radio Club will hold its 27th annual electronics equipment auction and flea market on Sunday, February 22, 1981, at North High School, Akron OH, from 8:30 am to 4:00 pm. Tickets are $2.50 at the door and $2.00 In advance. Even though It is suggested that you bring your own tables, some will be available for $2.00 each. Featured will be refreshments and prizes, including a first prize of a Kenwood TS-130S and two more prizes of Icom IC-2ATs. There will be plenty of room for buyers and sellers, including free parking. Talk-in on 146.04/.64. For more details, write CFARC, PO Box 6, Cuyahoga Falls OH 44222, or phone K8JSL at (216)-923-3830.

LANCASTER PA
FEB 22

The Lancaster Hamfest will be held on February 22, 1981, at the Guernsey Pavilion, located at the intersection of Rtes. 30 and 896, east of Lancaster PA. General admission is $3.00, except children and XYLs. Doors will open at 8:00 am. All inside spaces are available by advance registration only and are $4.00 each for an 8-foot space, which includes a table. There is a limit of 2 non-commercial or 6 commercial tables; the registration deadline is February 13, 1981. All vendors must set up between 6:00 am and 8:00 am on Sunday; reservations will not be held past 9:00 am without prior arrangement. Free tailgating will be available in a specified area outside if weather permits. Food will be served at the hamfest. Also, there are excellent restaurants and accommodations In the area. Call (717)-768-8271 for motel reservations under Sercom. Talk-In on 146.01/.61. For more information, write Sercom, Inc., PO Box 6082, Rohrerstown PA 17603.

VIENNA VA
FEB 22

The Vienna Wireless Society will hold its annual WINTERFEST™ on February 22, 1981, at the Vienna Community Center, Park Street, Vienna VA. The event will begin at 8:00 am.

MARLBORO MA
FEB 22

The Algonquin Amateur Radio Club will hold its annual indoor ham radio flea market on Sunday, February 22, 1981, at the Marlboro Jr. High School, off Rte. 85 on Thresher Avenue, Marlboro MA. Doors will be open from 10:00 am to 2:00 pm and sellers will be admitted starting at 9:00 am. Admission is 50¢. Tables reserved by February 15, 1981, are $5.00; after that date, they are $7.50. Talk-in on .52. For more information or reservations, contact Charles McCarthy W1BK, 128 Forest Avenue, Hudson MA 01749.

MINONG WI
FEB 22

The Wild Rivers Amateur Radio Club will hold a mid-winter swapfest on Sunday, February 22, 1981, from 10:00 am to 3:00 pm at the Minong Village Hall, Minong WI, 45 miles south of Duluth-Superior, 90 miles north of Eau Claire on Highway 53, and 135 miles from Minneapolis-St. Paul. Admission is $1.00 and tables are free. There will be a raffle drawing for a scanner. Talk-in on .28/.88 and .52. For information, contact Roger Doehr W9DLY, Route 5, Box 452, Hayward WI 54843.

LAPORTE IN
FEB 22

The LaPorte Winter Hamfest will be held on February 22, 1981, at the LaPorte Civic Auditorium (main floor), LaPorte IN, 50 miles southeast of Chicago.

Donations are $2.00 in advance or $2.50 at the gate. There will be plenty of room, good food, and tables which are $1.00 each. Talk-in on .01/.61 and .52. For more information, write LPARC, PO Box 30, LaPorte IN 46350.

GLASGOW KY
FEB 28

The Mammoth Cave Amateur Radio Club will hold its annual Glasgow swapfest on Saturday, February 28, 1981, from 8:00 am to 5:00 pm CST at the Glasgow Flea Market Building, 2 miles south of Glasgow on Highway 31E. There will be a large heated building with plenty of free parking. Each exhibitor will be provided one free space with table and chair. Additional spaces are available for $3.00 each. The building will be open for exhibitors at 7:00 am CST. There will be no forums or meetings—just door prizes, free coffee, and a large flea market. Admission is $2.00. Talk-in on .34/.94. For additional information, contact WA4JZO, 121 Adairland Ct., Glasgow KY 42141.

DAVENPORT IA
MAR 1

The Davenport Radio Amateur Club will hold its tenth annual hamfest on March 1, 1981, from 8:00 am to 4:00 pm at the Davenport Masonic Temple, Highway 61 (Brady Street) and 7th Street, Davenport IA. Tickets are $2.00 in advance, $3.00 at the door. Tables are $4.00 each with a $2.00 additional charge for an electrical hookup (limited number). Features will include over $2,000 worth of major prizes. Hotel discounts and refreshments will be available. There will be a pre-hamfest Saturday night banquet with Paul Graver, midwest ARRL SCM, as guest speaker. Banquet tickets are $8.00 and reservations must be paid by February 18, 1981. Talk-in on 146.28/.88, W0BXR. For advance tickets, dinner, and table reservations, write Dave Johannsen WB0FBP, 2131 Myrtle, Davenport IA 52804.

GRAND JUNCTION CO
MAR 7

The Grand Mesa Repeater Society will hold the second annual indoor Western Slope Swapfest on March 7, 1981, at the Lincoln Park Barn, 12th and Gunnison, Grand Junction CO. Doors will be open from 10:00 am through 4:00 pm and admission is free. Swapfest tables are $4.00 in advance. Attractions will include commercial exhibitors, a flea market, an auction, and prizes. Raffle tickets for the grand prize of a Tempo S-1 are $2.00 each. Talk-in on 146.22/.82. For further information, send an SASE to Larry Brooks WB0ECV, 3185 Bunting Avenue, Grand Junction CO 81501, or call (303)-434-5603.

MAUMEE OH
MAR 22

The Toledo Mobile Radio Association, Inc., will hold its 26th annual auction and hamfest on Sunday, March 22, 1981, at the Lucas County Recreation Center, Key Street, Maumee OH. Hours are from 8:00 am to 5:00 pm. The free auction starts at 10:00 am. There will be ample free parking all day and overnight. Tickets are $2.00 in advance and $3.00 at the door. Flea market tables are available; displays are limited to electronics and ham gear. There will be commercial exhibits, refreshments, door prizes, and a big raffle—all inside. Prizes include a Kenwood TS-130 with power supply, two Icom IC-2AT HTs, a Bird Wattmeter, and many more. There will be an additional ladies' program. Bring your YL, XYL, or OM and make a day of it. Talk-in on 146.52/.52. Area repeaters are 146.01/.61, 146.19/.79, 146.34/.94, 147.87/.27, and 147.975/.375. For additional information, write J. Honisko N8BGH, 1733 Parkway Drive N., Maumee OH 43537.

AWARDS

from page 23

enclose only three (3) IRCs with your application.

Joe Onizuka JE1WIH mailed me information about the NKDXC Award. Unless you work a lot of Japanese stations, the requirements are not as easy as it seems.

NKDXC AWARD OF JAPAN

The Northern Kyushu DX Club, Inc., issues the NKDXC Award to any licensed amateur or SWL station in the world.

Applicants must submit proof of confirmation of QSO with at least 20 different stations which enable you to spell "NORTHERN KYUSHU DX CLUB" using the last letter of each callsign. A station may be used only once in your spelling effort.

There are no band or mode restrictions, but special endorsements will be rendered for single mode or band achievements.

Do not forward QSLs. GCR apply. Forward your verified list with five (5) IRCs to: NKDXC Award Manager, PO Box 11, Yawata, Kita, Kyushu, Japan 805.

50-MHZ DX AWARD OF JAPAN

The award is issued in four levels of difficulty: Class EX—applicant must make 20 DX country contacts; Class A—applicant must make 10 DX country contacts; Class B—5 DX countries must be worked; and Class C—only 2 DX country contacts need be made.

While applicants are not required to submit QSL cards, they must have them on hand and verified by at least two amateurs or a local radio club secretary. Keep in mind, however, that all contacts must be made on six (6) meters, 50 MHz, utilizing any mode authorized.

Forward your claim and award fee of 8 IRCs or $3.00 to: Eiichi Konno JA7GZA, Awards Manager, 8-3 Tenjinmae, Henaizumi-town, Nishiiwai-gun, Iwate 029-31, Japan.

TEXAS INDEPENDENCE DAY

Brenham Amateur Radio Club will be operating its second annual special event QSL station to commemorate Texas Independence Day and its observance at the site where independence was declared from Mexico on March 2, 1836, Washington on the Brazos, Texas.

We plan to operate from 1600 UTC, Saturday, February 28, until 2300 UTC, Sunday, March 1, during times when the bands are open (no nets are scheduled) on the following frequencies plus or minus QRM: 3944, 7244, 14,344, 21,144, 21,444, and 28,544 kHz.

For an historic QSL card and information brochures, amateurs are asked to please QSL with an SASE (4¼" × 9" or larger) to BARC, WB5STR/5, PO Box 44, Brenham TX 77833.

Amateurs who worked WB5STR/5 last year should so indicate on their QSL and will be recognized this year.

We are grateful to Robert Fitzwilliam of Kay, Texas, for the use of his call which will be used with the phonetics, Washington on the Brazos, 5, Star of the Texas Republic.

LOVE OUR LIBRARY

The Lawrence County Amateur Radio Association is sponsoring a Valentine's Day theme special event from downtown New Castle, Pennsylvania, at our new public library on February 13-14, 1981.

We will be operating from the new library and the theme will be "I love my new library." The call in use will be KA3X, and the operating frequencies are: 147.795/.195 (our local repeater), 29.000, 21.400, 14.300, 7.250 and (CW) 7.125 MHz.

All frequencies plus or minus QRM (except 2 meters). Operating times are 1400-2200 GMT. Your QSL and $1.00 will bring a certificate.

For further information, contact John Hudak KA3X, 422 Galbreth Avenue or Zach Allerton KB3MC, 124 Richelieu Ave., New Castle PA 16101.

HAM HELP

I am in need of a schematic for a Micro-Z FM36 frequency counter with prescaler. I will be glad to pay copying costs and postage.

Dennis L. Cornell WD4HRO
7835 Captain St.
Millington TN 38053

Simon Langton Grammar Schools in Canterbury, England, are celebrating the centenary of the founding of the school in 1881. To this end, we shall be operating a special events station, active on all HF bands under the call GB4SLS, on February 22-28, 1981. During this time, we are anxious to contact as many past pupils of the school as possible, especially those who are licensed amateurs and residing in the United States.

Anyone interested in making a sked with us should contact either me or G3LCK, c/o G3OSL, Simon Langton Grammar School for Boys, Nackington Road, Canterbury, Kent, England.

Andrew P. Smith G4BBW
40 Virginia Road
Tankerton, Whitstable
Kent, England

I've had a bundle of letters and calls from readers requesting a source for the positive resist that I used in my article on easy PC artwork (*73*, June, 1980).

Yesterday, I found a source that you may want to know of since I am buying a private-label brand locally. The national brand is by GC Electronics, Rockford, Illinois. The catalog number is 22-233.

Route Electronics, Rt. 22, Springfield NJ, sells it for $13.60 for a large aerosol can. They do not mail order.

Ed Eggert W3HIK
2220 Marietta Ave.
Lancaster PA 17603

I need a copy of a complete schematic diagram or a manual for a Hallicrafters SX-100 receiver. I would prefer to copy at my end, but would pay for other costs.

K. Gilhuly KA8EWH
650 Ann Street
Harbor Springs MI 49740

I have a Regency HR-2A 2-meter transceiver that is sick. Anyone who can provide a circuit and servicing information would greatly assist me. I will pay for all expenses to copy them.

Harvey Horn WB2NMN
21 Skylark Lane
Stony Brook NY 11790

Searching for pre-32S-1 Collins transmitter in any condition to put on RTTY. If you have an old Collins AM/CW transmitter gathering dust and would part with it reasonably cheap, please send specifications, condition, and price. XYL is contemplating murder if I spend much money. I also need a CV-89 RTTY TU. Thanks.

Roger L. Arnold N5CAO
214 Hill Lane
Red Oak TX 75154

I need a schematic for a Kuhn model 357C VHF receiver and would like to copy and return a service manual for IC-21/DV-21 2m VHF gear.

Jung Y. Lem KB6BO
5222 Coringa Dr.
Los Angeles CA 90042

Does anyone have schematics for a Utica 650A 6m transceiver and a Gonset Super Six converter? Expenses will be reimbursed.

Howard Robb AF0W
340 So. 5th
Bird Island MN 55310

I would like to get in touch with someone who has completed the 220 transverter by Frank Kalmus WA7SPR in the October, 1979, issue of *73*.

Paul Ashmore WA9HEP
833 S. Chestnut
Litchfield IL 62056

Does anyone have any info on a lower sideband addition for a MULTI-2000? Also, who is handling the MULTI-2000 now? Any help would be appreciated.

Lloyd W. Locke K1COS

Reading MA 01867

FUN!

from page 26

9) A4XAA is:

1) The call used during a world-famous 1956 DXpedition
2) The Sultan of Oman
3) A four-land call that will eventually be assigned by the FCC.
4) A made-up callsign

10) Which of the following is a former reciprocal callsign held by Jordan's King Hussein, JY1?

1) EP1JY
2) 4Z4KH
3) RG8U
4) 7X2HM

ELEMENT 3—TRUE-FALSE

		True	False
1)	The newly self-proclaimed "Shah of Iran," son of the late Shah, is a ham.	_____	_____
2)	Until his recent automobile "accident," YN1AS was former Nicaraguan dictator Anastaslo Somoza.	_____	_____
3)	The DX Country Club Award is sponsored by *73 Magazine*.	_____	_____
4)	KA2BQ is a DX callsign; KA2BQV is not.	_____	_____
5)	To officially qualify as DX, a signal must travel more than 150 miles, no matter the mode or frequency.	_____	_____
6)	WWV, JJY, LOL, MGM, BOT, and RID are all standard time and frequency stations.	_____	_____
7)	The DX Operating Code says you should always call a DX station *exactly* on his frequency.	_____	_____
8)	KP2 is the new prefix for KV4.	_____	_____
9)	BV2A and BV2B are the only licensed ham stations in the Republic of China. Both stations are operated by the same person.	_____	_____
10)	"QDX?" is a Q signal meaning, "Is there any DX on frequency?"	_____	_____

ELEMENT 4—HAM ACROSTIC

Guess the words defined and write them over the numbered dashes. Next, place each letter in the correct square in the puzzle. The black squares show word endings. The completed puzzle will form a statement relating to amateur radio. (Illustration 2)

A) Five hundred miles is DX in this region 6 45 20
B) Popular DX mode 28 29 21 64 32
C) Twenty meters, for instance 42 60 74 76
D) "Shared" band 41 26 4 66 50
E) DXer's "shoes" 59 9 35 19 77 7
F) FCC authorization 49 73 51 5 40 23
G) Semi-automatic key 39 58 10
H) Conversation 12 33 43
I) Scarce DX 37 56 2 75
J) Distress Signal 71 22 13
K) Splatter 3 55 27
L) DE 72 1 52 44
M) Lots of DX in a row 8 61 25 62 53 36
N) When to work DX 34 24 57 46 31
O) Lids 54 63 17 18 11
P) Venezuelan prefix 78 15
Q) Temerarious DXer 48 47 65 67
R) To tell a DXer something 69 14 16
S) Computerized DX 70 30
T) Irish prefix 38 68

THE ANSWERS

Element 1:
See illustration 1A.

Element 2:
1—3. More than one budding DXer has made his first African contact through this fine service. Net time is 1800 UTC, daily.
2—3. A DXer's best friend.
3—1. Obviously not the 21st cycle in the history of the Earth, but only since man started counting—around 1750.
4—2. You may need a "long radio antenna" for this band, but that has nothing to do with LORAN.
5—4. If you chose "Cuba," I'll bet you didn't get your General ticket while the FCC was using its circa 1968 tests. A question similar to this one went a long way to giving the FCC its reputation for using tricky testing techniques.
6—4. Since six is allocated to broadcasting and other services throughout the most of the world, there aren't even 100 6-meter countries on the air.
7—1. When DXing on 80, it pays to know the allocations.

W	O	R	K	I	N	G	S	P	L	I	T

Illustration 1A.

8—3. But avid DXers also have many other picturesque terms for list-takers.
9—2. Ever get the feeling there's enough royalty in ham radio to form a club?
10—1. More royalty! King Hussein held this Iranian call before Khomeini. Ayatollah you so.

Element 3:
1) True—His call was EP1MP. Guess he's EP1MP/SU now.
2) True—And he was listed in *QST* as a Silent Key.
3) True—The more realistic DXCC.
4) True—KA2BQ would be one of the "U.S. Personnel in Japan." KA2BQV would be an amateur in New York or New Jersey.
5) False—If you ran ½ milliwatt at 300 GHz, twenty feet would be DX!
6) False—"BOT" and "MGM" are not stations.
7) False—Not really. The DX station's frequency should be left clear so everyone can hear him. In reality, this never happens.
8) True—Why? Only the FCC knows for sure.
9) True—Tim Chen, operator of both stations, uses BV2A on CW and BV2B on phone.
10) False—And "QRX?" means, "Are there any receivers on frequency?"

Element 4:
A—UHF, B—PHONE, C—BAND, D—FORTY, E—LINEAR, F—TICKET, G—BUG, H—QSO, I—RARE, J—SOS, K—QRM, L—FROM, M—STRING, N—OFTEN, O—GOONS, P—YV, Q—RASH, R—SAY, S—IO, T—EI. The completed message reads: R R QRK UR SIGS QSA VY ONE FOOT FROM PHONES ON GREBE FB OM HEARTY CONGRATULATIONS THIS IS FINE DAY. So began the first amateur European-American QSO on November 27, 1923, an exchange between French station 8AB and U.S. 1MO that opened the age of ham DX.

SCORING

Element 1:
Twenty points for the completed puzzle, or ½ point for each question correctly answered.
Element 2:
Two points for each correct answer.
Element 3:
Two points for each correct answer.
Element 4:
Two points for each correct definition. Give yourself 10 extra points if you unscrambled the message.

Okay, DXers, let's see how you *really* measure up. Remember, big guys, your 100-foot towers won't help you here!

1-20 points—Once heard a DL on 20
21-40 points—80 countries worked, 25 confirmed
41-60 points—DXCC material
61-80 points—250 + countries confirmed
81-100 + points—Honor Roll candidate

HAM HELP

I have some two-meter crystals that I would like to sell or trade. Frequencies available are: T 146.880, TR 146.250/.850, TR 147.840/.240, R 147.330, R 146.060, T 146.460, R 147.060, T 146.040, and T 147.930.

All above fit in HC-25/U holders. Specs are transmit fundamental mode and parallel resonant with 30-pF load. Divide transmit frequency by 12 to obtain crystal frequency. Receive specs are overtone mode, series resonant. Subtract 10.694 MHz and divide by 3 to obtain crystal frequency.

Crystals I need are 146.01/.61, 146/.47, 146.22/146.88, 146.28 transmit, and 146.46 receive.

If anyone will trade or tell me the going price of used good crystals or knows who can tell me, it will be greatly appreciated.

Kevin Neal

from page 65

front-panel keyboard which selects all of the radio's functions. All memory data and command instructions are permanently programmed into the memory unit which is an integral part of the microprocessor IC. As such, the 2008 cannot be altered to receive or scan frequencies other than those in its regular VHF/UHF bands.

The rig is unique in the fact that it is the only available synthesized scanner which does not have a searching capability. This should not prove to be much of a handicap, however, as many people who purchase a scanner are interested only in hearing the action on a predetermined set of frequencies. Thus, it is an ideal unit for the person who desires the convenience and economy of frequency synthesis, but who doesn't need a searching capability.

An interesting feature on this unit is a recessed button on the rear panel marked "Reset." This button is similar to the Clear key on a calculator and functions to erase all data which is stored in the scanner's eight-channel frequency/status memory. This is used to erase incorrect information on those few occasions when the microprocessor fails to initialize.

Memory data is retained when the unit is unplugged and during power outages by using a 9-volt battery stored in an easily-accessible compartment on the rear panel. During normal usage, the battery will last up to one year. If the radio is to remain out of service for more than several months, however, it is best to remove the battery to avoid possible damage due to electrolyte leakage.

An innovation over previous Realistic models is the selectable scan-delay circuit, which allows the user to program a two-second delay on individual channels. The channel lockout function is accomplished in a similar manner, using the front-panel keyboard. Delays and lockouts remain programmed even when the scanner is turned off.

Frequency and status information is presented on a bright, blue fluorescent display which includes the channel number and indication whether the channel is programmed with a delay or lockout, and the six-digit frequency readout.

The PRO-2008's more common features include on-off/volume and squelch controls, a 3" front-mounted speaker, front-mounted headphone jack, scan/manual control, telescoping indoor antenna, external antenna jack, and ac power cord (the scanner is not designed for dc mobile operation).

The scanner's circuitry is composed of an LSI microprocessor system, LSI phase-locked loop (PLL) frequency generation system, eight integrated circuits, 24 transistors, and 40 diodes. These semiconductors, along with a host of passive components, team up to bring you a superheterodyne dual-conversion receiver capable of synthesizing 18,160 frequencies.

The synthesizer circuitry is capable of being programmed to receive any frequency in the 30-50- and 144-174-MHz bands in 5-kHz steps, and between 410-512 MHz in 12.5-kHz steps.

The receiver sensitivity (for 20-dB signal-to-noise ratio) is 1.0 uV on the VHF and low bands, and 2.0 uV on UHF. This proved to be adequate for local reception using the built-in antenna. For serious listening, an external antenna is highly desirable.

Selectivity ratings for signals within 9 kHz of the intended frequency are down 6 dB, and those signals within 17 kHz are reduced at least 50 dB.

The scanner operates at a rate of 10 channels per second.

Audio output is two Watts maximum with the internal speaker. The unit consumes about 15 Watts when operating.

The large volume and squelch controls make for easy adjustment. Each control is marked with numerical logging indicators, making it easy to return to a particular volume/squelch setting.

Frequency coverage of the 2008 is a real plus; it will receive signals in the entire 410-420-MHz US Government band. While the lack of a searching function tends to limit the advantage of having this band, it didn't take me long to find a few noteworthy stations hiding out in this "forbidden" part of the spectrum. With a little luck and a copy of one of the better known federal frequency guides, anyone should be able to make a number of educated guesses concerning active frequencies in this band. Verifying your guesses is the fun part!

All in all, the Realistic PRO-2008 seems to be a good choice for the amateur who desires a synthesized scanner for use at home, office, or around the shack. While it has its shortcomings, it should be seriously considered by anyone who is planning on buying a quality crystalless base station VHF/UHF receiver.

The Realistic PRO-2008 is priced at $259.95. For further information, contact *Radio Shack, 1300 One Tandy Center, Fort Worth TX 76102.* Reader Service number 479.

GDX-1 DISCONE ANTENNA

With the flurry of activity in VHF/UHF scanner radios, it isn't surprising that someone has come out with a high quality discone antenna. Most antennas for scanner reception at present are simple vertically-polarized dipole clusters.

But the GDX-1 from TET-America is a different breed. Not only does it provide wideband reception, but it also is suited for transmitting as well.

Discone antennas are inherently wideband. The GDX-1 is designed for continuous coverage from 80-480 MHz. Feedpoint impedance is 50 Ohms unbalanced, so no matching balun transformer is necessary. The connector is a standard SO-239. Gain is stated as 3.0 dB, with a vswr typically less than 1.5:1 throughout its passband.

During transmit, the GDX-1 will safely handle 500 Watts PEP making it suitable for virtually any communications application. The antenna is deceptively sturdy, weighing a healthy 2.9 kg (6.4 pounds).

Our Field Test

The GDX-1 arrives in disassembled form with an instruction/parts-list sheet. Step-by-step assembly is a snap following the sequence. Hole tolerances are excellent, with elements and hardware lining up perfectly.

Our model, one of the first off the assembly line, had an unfortunate problem: The connector was threaded in metric! We notified the factory and were assured that subsequent runs had the problem corrected.

The parts count worked out perfectly after we figured out that a "biss" is a bolt and a "clipper" is a clamp. Something was lost in the translation. Purists may find the clamps slightly loose, but they may be bent slightly to tighten down on the elements.

The elements are solid rod, and high-quality tooling is apparent throughout the antenna. It is obviously thoughtfully designed and manufactured.

On the air, the GDX-1 performed better than most monitor antennas and had the additional flexibility of being frequency-agile continuously from 80-480 MHz. This allows operation on 3 amateur bands as well as reception on the 225-400 MHz military aeronautical band. (It's better not to transmit there!)

All things considered, especially with the assurance that the metric oversight has been rectified, the GDX-1 is capable of excellent performance as well as rugged immunity to wind. For further information, contact *TET USA, Inc., 425 Highland Parkway, Norman OK 73069.* Reader Service number 477.

MFJ-1040 DELUXE RF PRESELECTOR II

An unusual combination of accessories in one cabinet has been released by MFJ, a company noted for their large catalog of accouterments for radio communications.

The new 1040 Deluxe Rf Preselector II houses both a flexible receiver preselector and an adjustable-delay relay to protect the delicate circuitry when used with a transceiver. Very thoughtful and very effective.

Designed with applications agility in mind, the 1040 features at least 20 dB of preamplification. More important, the 1040 doesn't introduce considerable circuit noise as do some other rf preamplifiers.

Q is sharp, awarding the listener with good out-of-band rejection of unwanted signals. Gain may be continuously varied by a potentiometer or attenuated by 20 dB in one increment by pressing a button.

Circuit protection is automatic; when transmitted rf is detected by a high-gain sampling circuit, the antenna relay is automatically switched, bypassing the preamp. A front-panel pot may be adjusted to tune the receive delay—a sort of VOX—to prevent constant relay dropout during SSB excursions. Delay may be varied from 0 to about 2 seconds.

The dc amplifier used to control the relay consists of two direct-coupled bipolar transistors; sampling from the antenna circuit is through a 12-pF capacitor and rectified by two 1N34 diodes.

The preamplifier circuit is built around a 40673 dual-gate MOSFET. Preselection is accomplished in four bands (1-54 MHz), switching among four standard rf chokes, each of which becomes part of a tuned tank when connected across the 320-pF main tuning capacitor.

Rear-apron connectors in a row (SO-239s and phono jacks in parallel) allow selection between two antennas and two receivers by front-panel pushbuttons.

When the 1040 is switched on, a red LED signals the status. When switched off, the antenna circuit automatically bypasses the electronics so that the rig feeds the antenna straight through.

The preselector may be powered by an external source of 9 to 18 volts dc or by its companion ac adapter.

Our Test

We were impressed at the small size and large flexibility of the MFJ-1040. Two tests were performed, one with a general coverage receiver, the other in a full transceive mode.

First, the 1040 was connected to the antenna input of a Kenwood R-1000 receiver; a 135-foot dipole was connected to the input of the preselector.

With the preselector still switched off, signals came into the receiver, business as usual. But with the preamplified preselector switched on and adjusted to frequency, dead bands came alive! Keep in mind that 20-dB gain is equivalent to more than 3 S-units, and that amount of signal brought up out of the noise can be heard!

Tuning the receiver throughout the range of the 1040 (up to 30 MHz—we did not try it through 54 MHz although there was no question that it would work there), we determined that its gain was high and its selectivity was sharp. Out-of-band images and intermod were reduced considerably and in many cases eradicated. The continuous adjustability of the gain stage made custom preamplification a snap.

The contacts on the antenna-selecting push-buttons showed good isolation; high-level signals were barely detectable when the receiver switch was pushed to an alternate output.

A rear-apron jack provides the ability to remote-control the unit from a pair of shorting (or grounding) contacts in the transceiver.

Next, the 1040 was connected to the station rig, a Triton II. Since the preselector is rated to withstand 350 Watts PEP, we weren't concerned that we might cause injury pumping 150 Watts or so into the unit.

Trying the combination first on ten meters, we were astounded at the increase in signal levels *without* a corresponding increase in background noise. Double-checking this performance, we cranked the Triton's gain control down to just below signal threshold; switching the 1040 on, signals came in loud and clear!

We repeated the exercise on all five bands with equal success.

Next, we decided to try to burn the unit out with rf! During transmit, the relay responded instantly. Releasing the mike button, we heard the reassuring sound of the relay drop back to receive, accompanied by signals once again.

Transmitting again, we varied the settings of the VOX delay control as we spoke into the microphone and then released the button. Delay times were adjustable from 0 to roughly 2 seconds, which would accommodate any amateur mode: CW, AM, FM, SSB, RTTY, and even SSTV!

For older rigs of questionable sensitivity, or even when used with modern rigs where threshold signals must be improved, the MFJ-1040 is hard to beat. Its preselection should improve the performance of virtually any receiver or transceiver operating within its design range. For further information on this $99.95 product, contact *MFJ Enterprises, PO Box 494, Mississippi State MS 39762.* Reader Service number 476.

THE PRACTICAL HANDBOOK OF AMATEUR RADIO FM AND REPEATERS

Anyone who regularly reads Bill Pasternak's *Looking West* column in this magazine undoubtedly will have more than a passing interest in his new book, *The Practical Handbook of Amateur Radio FM and Repeaters*, written with Mike Morris and published in 1980, at $9.95, by TAB Books. Actually, anyone who has more than a passing interest in FM and repeaters will find this book a valuable addition to his technical library. This 538-page volume is more than just a practical handbook—it's a complete one! Among the topics covered are the history of repeaters and FM, how to determine your needs when planning a repeater, frequency coordination, ATV and RTTY repeaters, and a wealth of other general topics.

There are several chapters on the "people" end of repeaters, with extensive detail for repeater users and repeater owners. There is solid useful information on handling malicious interference and the "wild turkey." Hams looking for specific technical information won't be disappointed either; using no references other than this book, you could build a sophisticated repeater system incorporating every bell and whistle known to the repeater world. The operative word here is thorough!

Perhaps your interest in FM and repeaters is limited to kerchunking local machines with the synthesized transceiver you got for Christmas. Maybe you are a trustee or technical consultant for a big repeater operation. Whatever your level of interest or expertise, this book will enrich the hours you spend involved with FM and repeaters. For further information, contact *TAB Books, Inc., Blue Ridge Summit PA 17214.*

THE ARRL OPERATING MANUAL

The ARRL Operating Manual, recently published, continues the League's tradition of supplying the ham with some of the best book bargains available today on the subject of amateur radio. Inexpensively priced at $5.00, this large-format, paperbound edition is a compendium of up-to-date information on all phases of amateur radio.

What the League's *Handbook* does for the technical aspects of our hobby, the *Operating Manual* does for the stylistic. In short, it can help almost anyone become a better operator, and it will be particularly useful to those of us who find ourselves getting involved in some new aspect of the hobby such as computer RTTY, OSCAR, traffic handling, or even contesting.

The *Manual* provides an interesting solution to the problem of publishing an authoritative text on all the diverse aspects of our hobby. Rather than trying to do the impossible (finding one author conversant with all phases of ham life), the *Operating Man-*

ual incorporates the talents and knowledge of fourteen authors, each of whom writes a chapter on his/her specialty. The result is a definitive collection of chapters on subjects as diverse as traffic handling and DXing, written by enthusiasts who know what they're talking about.

Other subjects covered include: rules and regs., SWLing, emergency communications, contesting, awards chasing, FM and repeaters, VHF/UHF operating, satellites, visual communications, and microcomputers.

In addition to being well edited, the *Operating Manual* is liberally Illustrated. The extensive use of figures, photos, tables, charts and even an occasional cartoon provides a refreshing change from the staid layouts of other League publications.

For example, the chapter on contesting has several sample logs and dupe sheets. The chapter on DXing includes sample propagation charts, a tabular listing of countries organized by rareness of prefix, a list of international ten-meter beacons, and a sample azimuthal, equidistant map of the world used to determine great-circle bearings. The chapter on visual communications features slow-scan TV picturers, weather satellite photos, and even some efforts at RTTY art.

These chapters are typical of the treatment most topics receive in the *Manual*. While it is impossible to discuss all the subtleties of some of the more technically complex topics in a single chapter, the *Manual* does provide the neophyte with more than enough information to allow him to get oriented in unfamiliar terrain. In this vein, each chapter usually suggests additional reading material or supplies lists of information sources.

The ARRL Operating Manual is filled with good things, and the very richness of its content reflects the incredible diversity of our hobby. It will be a valuable reference work for anyone exploring the vast landscape of amateur radio. If you are as concerned about your operating style and skill as you are with the purity of your emissions, or if you plan to become involved in some new aspect of the hobby, you'd do well to get a copy. The chances are good that it will answer lots of questions you've had in your mind. For further information, contact the *ARRL, Newington CT 06111*.

10-METER FM FOR THE RADIO AMATEUR; THE 10-METER FM HANDBOOK

One of the most interesting aspects of ham radio is building or modifying your own equipment. Unfortunately, equipment has gotten so complex and expensive that most hams have restricted their building and modifying activities to small accessories for their stations. Digital clocks and electronic keyers abound, but if a device is part of the station's rf chain, the chances are that it has the nameplate of a commercial manufacturer affixed to it, and its owner shakes with fear at the thought of taking a soldering pencil closer than three feet to his/her thousand-dollar electronic baby. Now, that's all well and fine; with today's crowded band conditions, I am somewhat relieved that such fine commercial gear is available. Most hams do not have the facilities to build and properly adjust their own SSB equipment to the level of quality available from manufacturers, and even if we could compete technically, we'd find the expense (time as well as money) prohibitive.

OK, so we intellectually accept the need for that expensive little box on the ham-shack table, but somehow that doesn't stop the urge to warm up the soldering iron and jump into something feet first. You say you have three digital clocks and two electronic keyers, and you still want to build something? I know the feeling. Relax. How about 10 FM?

Yup. There is a lot of FM activity up around 29.6 MHz. Very little QRM, the atmosphere is freewheeling, the technology is up to date, and yet the equipment is very cheap. If you know someone who is active on 10-meter FM, the chances are good that he uses a converted CB. Whatever he is using, he'll tell you that he is having a lot of fun.

What all this is leading up to is the recent release of two rather good books on the subject of 10-meter FM. If this mode interests you, you really should have copies of them. While each author emphasizes a different aspect of the mode, both give an excellent introduction to all the various facets of 10-meter FM. Both cover repeater operation, frequencies, antennas, equipment, and equipment conversion.

How do they differ? Dave Ingram's book goes into greater detail on a wider variety of subjects, but Bob Heil's book (the *Handbook*) is the most complete source of information available on converting CB rigs that use the popular PL02A three-crystal-synthesizer configuration. If you are planning to convert a rig that uses this configuration, Bob Heil's book will prove to be extremely useful. If you are planning to get on the air using a different approach, or just want to know more about this mode, Dave Ingram's book might be more interesting to you. Both books tell you all you need to know to begin enjoying 10-meter FM, and at $4.95 each, these 1980 publications are relatively inexpensive; I'd get both of them! For further information, contact *Melco Publishing, PO Box 26, Marissa IL 62257* for Bob Heil's book and *TAB Books, Inc., Blue Ridge Summit PA 17214* for Dave Ingram's book.

DIGITAL ELECTRONICS: A HANDS-ON LEARNING APPROACH

Digital electronics has really arrived, and it's here to stay; it's getting hard to find a piece of ham gear that doesn't incorporate some digital circuitry. All of us have absorbed a remarkable amount of the new technology, but many hams have wished for a complete, step-by-step introduction to the subject. If you learned electronics the way I did, by reading whatever books and magazine articles you could get your hands on, you just might find this book useful. The author assumes that the reader has no previous knowledge, so nothing is skipped or glossed over. He begins by explaining how resistors and diodes work, but when you are through with the book you'll be comfortable with microprocessors. Best of all, the book is a true hands-on approach, so most subjects include a carefully explained project to carry out on a solderless breadboard. You say you don't have a solderless breadboard? Shame on you! As the author points out, if you really want to learn about this stuff, you are going to have to jump in and *do* it.

Fortunately, doing it is exactly what the author has in mind, and he has provided lots of valuable information on the mechanics of building digital circuits. He has thoughtfully included chapters on troubleshooting, circuitboard construction, and even the electronic color code. He starts with very simple projects, but the meat is there too; after working your way through this book you won't have to make excuses for your lack of knowledge on the subject. The digital revolution has been going on for a long time now; why not join the fun! Copies of *Digital Electronics: A Hands-On-Approach* (by George Young, 1980) are available at $8.95 from the *Hayden Book Company, Inc., Rochelle Park NJ.*

121 N 59th St.
Philadelphia PA 19139

NEW PRODUCTS

from page 30

board. It is designed for the 50, 144, and 220-MHz bands and may be modified for use on adjacent commercial and government bands. It is used for control links, repeater service, telemetry, and other applications for which a small unit is required. A multichannel adapter is also available to extend operation up to 5 channels.

Features include low-impedance dynamic mike and high level audio inputs; crisp, clear modulation; low spurious output; pre-wound coils; adjustable output level, and built-in test points for easy alignment. A commercial-grade, frequency-stability option is available.

Another new development at Hamtronics is the availability of XV2 2-meter and 1¼-meter transmitting converter kits with 6-meter inputs.

For further information, contact *Hamtronics, Inc., 65F Moul Rd., Hilton NY 14468.* Reader Service number 481.

PALOMAR ENGINEERS TRANSCEIVER PREAMPLIFIER

Palomar Engineers has announced a new preamplifier which is continuously tunable and covers all amateur bands from 160 through 6 meters. It provides 20 dB of gain with a dual-gate FET for low noise figure. The gain and low noise figure improve reception on most receivers, particularly on the higher frequency bands. The added selectivity reduces image and spurious response.

Gain is continuously variable to prevent overloading the receiver. An rf-sensing circuit allows the unit to be used with transceivers; the preamplifier automatically bypasses itself during transmit. The fail-safe switching circuit handles transceivers to 350 Watts. Connectors are SO-239. The preamplifier measures 8" × 5" × 3" high and features brushed-aluminum control panels.

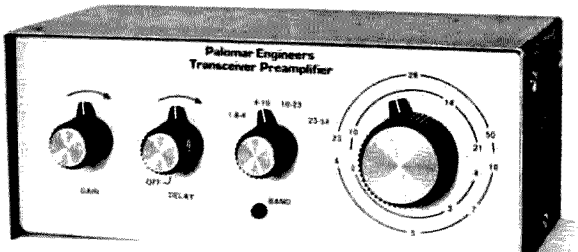
For a free descriptive brochure, write *Palomar Engineers, PO Box 455, Escondido CA 92025.*

CDE HAM ROTOR FOR THE VISUALLY-IMPAIRED OPERATOR

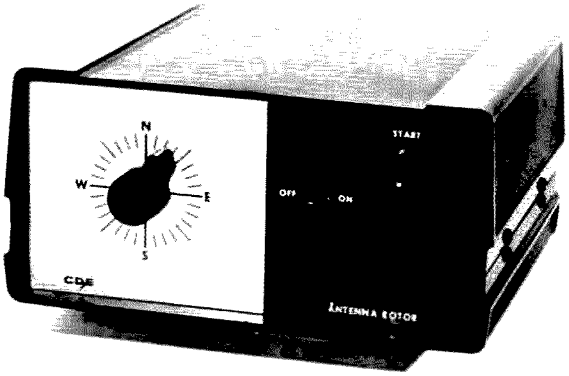
Cornell-Dubilier Electronics has produced a rotor system especially designed for sight-impaired amateurs. The Ham-SP is a combination of the Ham-IV rotator and a solid-state control unit.

All operation functions of the control unit, 360° compass dial, on/off switch, and push-to-start button, are marked visually as well as by Braille. To operate the system, the desired antenna direction is selected by turning the large dial. The start button is then pressed. Electronic circuitry will automatically retract the wedge brake and start the rotator turning to the desired direction. During the time the rotator is turning, a high-pitched tone is emitted. When the rotator reaches the predetermined direction, power is removed from the motor, it is allowed to coast down about 5 seconds, and then the wedge brake is engaged. When the rotator stops, the tone stops, indicating that the antenna is now at the desired location. (Neither the rotator nor the control unit are compatible with other CDE rotor systems.)

For further information, write to *Cornell-Dubilier Electronics, Department SP, 118 East Jones Street, Fuquay-Varina NC 27526.* Reader Service number 484.



The Palomar Engineers Transceiver Preamplifier.



The CDE Ham rotator for visually-impaired amateurs.

HAM HELP

I am in need of any libraries of *73, QST, HR, CQ,* or any other amateur or electronics oriented publications. Anyone wishing to clean out the bookshelves, please contact me on any offerings. Thank you!

RTTY LOOP

from page 16

terminal. "Stupid," you ask? Well, a dumb terminal, commonly called a glass Teletype, just inputs what you type and displays what it gets. Smart terminals can do all kinds of fancy editing and other neatniks. This one is somewhere in between. With the resident 6800 and some RAM it could be given some smarts with the appropriate programming, but remains of limited usefulness if what you really need is a computer terminal.

Next month I will take a look at some bells and whistles available for the ATR-6800 and describe a typical on-the-air session. It promises to be a real eye-opener!

LETTERS

from page 28

the communication . . . phase of the art." as listed in Part 97.1(d).

Thanks for lending an ear. I like *73* much better than "the other one," but I agree that perhaps you might have at least one feature for the beginner or Novice operator.

Cindy Dalmadge KA0IMG
Colorado Springs CO

NO PRICE

Your editorials are *first* reading! I agree—the advertisers who put no price on a new piece of gear make me so damn mad that I won't buy it.

I need an antenna switch and saw a new one advertised in *73*—but no price. Should I spend 15 cents and my time for a letter to the manufacturers?

I know what I can afford. So if it's out of my price class, I'd like to know *now*.

John Cowley WA6PBM
Rosamond CA

GOLDWATER

Enjoyed the article in the November *73* issue on Barry Goldwater K7UGA. I had a short QSO with him a few years ago.

Here is a man who has supported amateur radio in that maze of bureaucracy in Washington DC for many years. The Senator is a man who for years has told the general public just the way it is. We have too many politicians who beat around the bush and tell each group just what they want to hear, sometimes distorting the truth.

Wish we had more people in his position who would support our hobby. We as hams must speak up and band together before we find ourselves on the outside looking in.

Alfred L. Pedneau K5HKG
Pineville LA

BUY AMERICAN

Thank you for your comments in Never Say Die and especially DX. I feel the comments on the amateur situation are well taken. Just today I wrote another magazine to criticize an editorial on basically similar topics. This other magazine recommended dropping the code requirement and relaxing the testing standards to allow thousands of new "amateurs" to come into our ranks. The proposed reason for this was to help the American radio manufacturers compete with the Japanese companies.

It is my opinion that we already have too many undisciplined amateurs causing interference. Just recall the recent hurricane nets. If the code and theory requirements do nothing else, they do force one to discipline one's self to learn these.

In coming into amateur radio, I believed the purposes were those set forth in the FCC rules, not to see how many radios we can sell. I am pleased to hear about all the experimentation which amateurs are doing even in modifying new, commercially-built rigs.

Amateur radio can fulfill a useful purpose in the country as long as it remains organized and disciplined. This should be more than a hobby. Let us not invalidate our purposes by making it a glorified CB band.

This other magazine I referred to also indicated that Japanese equipment was better made than American. I have had the most recent solid-state HF rigs from Yaesu, Kenwood, and Drake, and find the TR7 to be better than any of the others. The Japanese rigs looked good and had all the bells and whistles, but my experience thus far has been that some of the knobs, such as noise blanker, speech processor, i-f shift, notch filter, etc., did not work or worked poorly. However, with the Drake, I had to pay extra for many items, but they seemed well engineered and worked well. It is not so much the looks but how it performs that counts. It seems in many cases that you still get what you pay for. I find nothing revolting in the suggestion we attempt to buy American first.

Tim Johnson N5BTE
Bristow OK

BLUE FROG

I read with interest your explanation of why your radar jamming didn't work as well as why commercial units don't work. I must agree that they do not. However, I can't agree with you on the reason why.

You state that if the jammer is a mere 3 kHz off of the radar gun frequency that the radar gun will not pick up the jammer. This is not so; radar guns are very wide on receive and drift a huge amount on transmit. The 3 kHz you mention is nothing. I can change the frequency of a gun oscillator that much by blowing on it. If you don't mind, let me explain the error of radar jamming and how to correct it.

First of all, the thing that people do not realize or tend to ignore is that police radar is built to display the fastest speed from many doppler signals. Now, if you jam at, say, 50 mph, as most commercial units do and drive over that speed, the radar unit will first pick up 50 because the jamming signal will be stronger than your reflection. But as soon as you come within normal range if you are driving faster then the jam speed, he will pick up your speed just like the jammer wasn't working.

So, the only thing you can do is to jam at a much higher speed than what you are traveling, hoping that the policeman will not believe his radar unit. Let's say you like driving at 70; you should jam at around 110 so that his unit will pick up 110 and he won't believe you are traveling that fast. He will then ignore the reading and you. But this only works with still radar. For moving radar you must use a different method.

Moving radar is really taking two readings, the police car speed and the combined speed of his car and your car. It first picks up the signal bouncing off a tree or grass, etc., and gives his speed, then it looks for a much higher speed which is that of your car approaching his. It then subtracts his speed from his and your combination which leaves your speed. But moving radar, like still, looks for the fastest speed.

So, if you jam at 110 and drive 70 and he is moving 50 then his unit sees two speeds. The jam of 110 minus 50 which gives 60 and 120 minus 50 which gives 70. His unit will display 70 and you are in for another ticket. So, we are back to giving him a reading that he won't believe if you want to jam him.

Let's say you like to drive 70, then a good choice for a jam speed is 150. If he is driving 55 or less, then his moving radar will show 95 or more which he probably won't believe. The faster you travel, the faster you jam at. The best all around jam speeds seem to be between 150 and 170. This way you will get still, as well as moving units.

In cities or where the speed limit is something other than 55, you must modify this method to the best speed. Also, the modulation is important. The best results are gotten with a square wave with a 50% duty cycle. Radar units tend to ignore sine waves. I would dare say that if you modulated your 10-GHz transmitter the proper way and for the proper speed, it would do a fine jamming job even if it is in the ham band. A good modulator can be made from a 555 driving a voltage regulator driving the Gunn source.

All of what I have said is based on my personal experience. Some friends and I have worked many months with our own radar units to perfect a good jammer. It has never failed to jam any X-band radar unit I have come across and you should see the look on the small-town policeman's face when you drive through at 20 and he reads 90.

But all in all, it's not worth the risk because jamming is never a sure thing. The best thing to do is get the best detector on the market and take your chances.

I must say that you are welcome to print this but not my name or address. I don't need the law knocking at my door as well as the kooks of this world. So, for my protection, just sign me,

Blue Frog

OK, Blue, serves me right for listening to "experts" on radar. You sure won't see me messing around with jammers and then trying to explain in court that I really wasn't going 110, as the radar read out.—Wayne.

NO DUMBBELL

I have just completed a CW chat with a relatively new Extra whose fist was comparable to that of a brand new Novice!

The point I am trying to make is that this learned gentleman is being given the privileges of a full-blown Extra class amateur, but cannot perform the simplest of Novice requirements in the field of sending code. At the same time, I and many other Generals are being deprived of the few additional privileges of an Advanced class license because we don't know what a reflex klystron is used for, and because Dick Bash came up with an idea for teaching aspiring hams some inside facts about radio theory and how to pass the FCC tricky-tests.

The fact is that the ARRL and Ameco came out with FCC questions and answers a long time ago, with complete approval of FCC. I know, because I studied them until I could answer them forward and backward, and I studied every other piece of information I could get my hands on that dealt with the outline FCC said we would need to understand when we took the test. I knew how, when, where, and why but what I got was a set of questions that were far afield from the FCC outline and the test was as simple as if it had been written in Greek.

A friend heard about Bash and got his *Final Exam*, studied it diligently for weeks. You see, Mr. Bash teaches how problems are worked and why the answers are what they are. He teaches the subject while he gives the answers. My friend passed easily...so I got the Bash book.

My test came one month after by friend had taken his and by that time, the FCC had decided to go after Bash. Again, I had added Ameco and ARRL to my studies, along with the Bash book, but again they beat me to the draw and I got a set of questions printed on brand new, crisp paper. Three questions were similar to the ones in the Bash book but *six* were taken almost word for word from the ARRL questions and answers in the Extra class section of their training manual!

Another friend of mine went to Tulsa the following month, after having failed (as I did and all but one of the other Advanced aspirants did who took the test in Oklahoma City), but he ordered Mr. Bash's updated *Final Exam* that contained something like four hundred questions and answers! He, too, had studied every other book he could get his hands on. Imagine his chagrin when, for the third time he was handed a crisp, new set of questions, which dealt with doodads he had never heard of!

Let me close by saying that I am a retired airplane driver. I logged some twenty thousand hours of accident-free pilot time and taught scores of others to fly, including Military Cadets, but I can't design an airplane, weld a piece of tubing, splice a cable or spray paint a fuselage. I passed every written test I took from FAA on the *first* try, so I think I am no dumbbell!

If an Extra class amateur can get his ticket and all those privileges when he sends code like a new Novice, why are we Generals flunked because the FCC wants to annihilate Dick Bash for doing what ARRL has done for years and we don't happen to know what the angle of conduction is in a Class AB amplifier?

Loren Carlberg WB5WDG
Muskogee OK

CORRECTIONS

In my article and computer program, "The Odd Couple," in the November, 1980, issue of *73 Magazine*, page 110, a line of code was dropped somewhere. Please insert this statement so that the channel 6 calculation will work: 620 L=23•F. Also, a parenthesis should be put around part of line 405: 405 J=95.8−(1.48•D)

For those not familiar with Level I "shorthand" and who are trying to translate the listing, see the accompanying table.

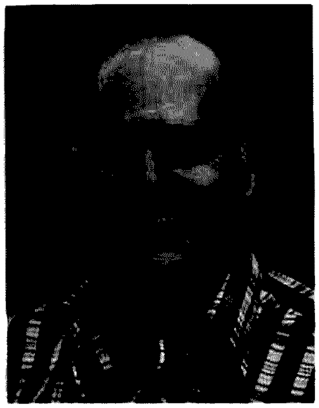
W2NSD/1 NEVER SAY DIE

editorial by Wayne Green



BUY AMERICAN

The other day I met a chap who mentioned that *he* had bought an American car and thus was not supporting the Japanese. Some of our American ham manufacturers are waving a similar flag. As the user of Japanese ham rigs, Japanese cards, Japanese hi-fi, Japanese cameras, Japanese calculators, Japanese cassette players, etc., perhaps I can put this into some more realistic perspective.

Firstly, in case there is any red-neck reaction that I'm not a patriotic American, I would like to point out that I was right along there with everyone else in WWII. Secondly, having now visited nearly 100 different countries I am in a position to say with authority that I have yet to visit another country that I would prefer to the US. I am not in any way blind to the manifest faults of our country, it's just that even with them it is better than the others.

Those of you who have read my editorials know that I am not reticent about writing about things which I feel should be improved about our country. It is in that respect that I would like to comment upon the subject of imports. One of the great hopes that I have is that the Reagan administration will be able to curb the growing socialism which has weakened our country and that they will be able to stop the growth of government control of us all. There may indeed be ways that some of the more obvious agencies can be made to provide value to all of us, but until then I can only be distressed by HEW, OSHA, FTC, and some agencies which I don't even dare to name for fear of reprisal. They have unlimited funds to harass me and a history of using them for that purpose on others.

The United States could be competitive with other countries but for several problems. One is the tax situation. I've just recently opened a production plant in Ireland to put out Instant Software packages for sale in the European and Middle Eastern countries. If I want to buy a piece of production equipment in the US, I not only have to pay for it up front, I also have to buy it from profits. This means that in essence I have to pay double for it...less a small amount for an investment tax credit. If I want to put up the same machine in Ireland, I find that not only are there no requirements for using profits for this, but that the government is standing ready to put up about 50% of the cost of the equipment. Thus the bottom line to me is a cost of about four times as much to get the new equipment for production in the US as in Ireland.

Much has been written about the efficiencies of foreign production through their use of modern production equipment. This keeps cost down and makes a firm more competitive. Until such time as the tax situation here changes, I fear that the US can only fall further behind in production efficiency. Productivity, it is called.

In the car industry there are other problems. No doubt you've seen pictures of the automated Japanese car plants. Why don't we have those here? One reason is the high cost, where the machinery needed costs several times as much because of taxes and no government help. Another is the fierce resistance of the auto unions to anything which will cut down on the number of workers needed. That would be okay if all other countries would do the same. Unions, as a matter of course, bitterly fight automation. Add to that the wages achieved by our auto unions...double the average American wage...and you see why Detroit has no chance of being competitive with foreign firms.

Should we set up limitations on imports? This will bring on similar limitations on our products...and not so much on those which are not competitive as those which are. That is a losing battle and it takes a keen insensitivity to history to recommend limitations on imports.

Three years ago I foolishly went out and ordered an American car. I have lived to regret that impulse. It was a Dodge. The first thing that happened was that I was ripped off by the dealer for $200. I put down a payment with my order...and though the dealer was unable to provide the car, he still kept the $200. I complained to Chrysler and they said, in effect, tough. I did get the Dodge from another dealer when the first was unable to get it in a reasonable time. The car worked for a few weeks and then the engine stopped being dependable, stalling and being unstartable more often than not. The local Chrysler garage tried to fix this, coming up with many approaches. None has succeeded and it still goes through the process of starting up...running for a few minutes and then stopping. Oh, it *can* be started if you take the engine cover off (it's a van) and pour gas into the carburetor directly.

COVER: Talk to the world through your 2-meter handie-talkie! Metroplex, the New York City metropolitan area's most sophisticated system of inter-linked repeaters, has over 400 members, including 50 overseas amateur radio operators!

Metroplex was conceived in January, 1978, by K2KLN and WB2MGB to: establish repeaters on *all* allocated FCC frequencies; use all available modes; provide 24-hour emergency communications; and provide a forum for east coast and worldwide amateur radio operators, via a 2-meter/10-meter FM link. Club members have already contacted over 35 countries on 4 continents through the 10-meter link.

Autopatch facilities are completely computerized and are part of a large long-distance network which includes trunk lines, satellites, and emergency speed-dial numbers. All frequencies are coordinated through T-SARC.

Listen to Metroplex FM on 29.640/29.540 in, and on 145.450/144.850, 223.720, and 443.950. For further information, write PO Box 237, Leonia NJ 07605, or call the 24-hour club phone, (201)-592-1579, to request an information package. (Photo of Hank Goldman WA2OVG by Larry Mulvehill WB2ZPI, Cold Spring NY.)

Nothing else known to man will start it.

The purpose of the van was to provide a work area for me while I was traveling to club meetings and on business trips. The van bounces so badly that it is useless for this. The shocks rattle, the thing falls apart faster than a team of ours can put it back together. It is a disaster.

Compare that to the Mazda RX-7 which goes like spit, has caused virtually no problems, does not bounce or rattle, and gives us almost twice the gas mileage. It does not have quite the room of the van and seats two instead of ten, admittedly. It does not have room to mount a typewriter, but then what good is a typewriter if one can't hit the right keys because it is bouncing around so much? The Chrysler reaction to my problems has mainly been one of it being my fault for buying the car, not any serious effort to see what they can do to solve the problems.

Much has been written about the problem of productivity, but the basic reasons for it are still untouched. I think that American firms could compete with the Japanese if we had just two major changes. One would be a tax change which would encourage automation and modernization. The other change needed is some sort of enormous growth in the number of hams in America so we would again be competitive technologically.

When I bring up growth of amateur radio, I'm no longer thinking in terms of trying to get back to the 11% growth we had before Incentive Licensing was proposed in 1963, when we went to a negative growth. We're over one million technicians and engineers behind where we should be and we desperately need to play catch-up.

The future is electronic, whether you are looking at computer, entertainment, communications, or automation. We're heading into an era of satellite communications which will reach right down to every office and home. We're looking at more and more of our home and office equipment going electronic. Just a few weeks ago I saw the prototype of a microprocessor controlled ski binding. We're going to have to adjust to electronics playing an important role in our life over the next twenty years and that means that we must have the engineers and technicians to design, build, install, operate, and service all of this stuff.

In that light we don't need a 10% growth, we need a 50% to 100% ham growth for a few years. Whether this is something which can be done under the present regulations or not, I don't know. It may be that Radio Shack can help. It may be that an aggressive approach by ham clubs, invading our high schools, will do the job. We may need every attack we can think of... but somehow we must get growth of amateur radio if we don't want to see our industries fall further and further behind.

250,000 NEW HAMS?

The fantastic success Tufts Electronics has had in getting new hams licensed gave me an idea. First, let me explain that Tufts took a back part of the store and set up an area where Novice classes could be held. The classes have been gaining in popularity and the graduation of about 90% into licensed hams has been experienced.

One minor note. Tufts contacted the League for help in getting an outside ham to come in and give the Novice license exams. The chap they recommended was contacted and my understanding is that he refused to give the exams except for $5 each... however, for that price he guaranteed that everyone would pass... presumably even if he had to help them do the test.

At any rate, the idea that came to me one morning was to try to interest Radio Shack in setting up ham classes in all of their 5,000 company-owned stores. If they were to set up to handle ten to twenty people, it would not take a lot of room, and would have a large number of benefits to Radio Shack... and obviously to amateur radio, too.

If these stores only provided 50 Novices per year, this would be a total of 250,000 new hams per year. At that rate we might catch up with Japan in engineers and technicians within five years and have a chance at getting back the technological ball in electronics.

The plan would be for the classes to run for ten weeks, with class time spent mostly in teaching the students the theory they will need for the Novice ticket and as a foundation for the General ticket later on. They would also be taught the rules and regulations, plus all sorts of background about amateur radio which they will need as amateurs. The teaching would be largely by way of video tapes which I would provide. I'm set up to make tapes now and have the experience of our audio cassettes on Novice exams.

Well... I Can Dream, Can't I? **by Bandel Linn K4PP**

"We were just driving by and noticed how low your antenna is! Is it all right if we put it up 200 feet... just for kicks?"

The Morse code would be taught mostly via audio cassettes. . .and we *do* have the best series for that yet produced by anyone. The study manual would also be available from *73* . . .one of the few study manuals which stresses understanding the basics instead of just memorizing questions and answers.

New hams need to have some background in how to operate, how to tune a rig, what swr is and how to use an swr meter, etc. They should know about DX and how to work it. . .understand about contests and the many other phases of amateur radio such as RTTY, SSTV, FAX, microwaves, repeaters, and so on. These are a natural for video tape. This would make the courses both interesting and informative, providing constant lifts of enthusiasm for the hopefuls. It can get very discouraging at times, so one has to remember that these classes *are* show business.

The exams and help with questions could be provided by nearby ham clubs.

The course should not be given free since that encourages people to drop out when some conflict makes them miss one class. I suggest a charge of $50 to cover the costs of the space, the code tapes, the study manual, a code practice key and buzzer, and the use of the video tapes. This would bring in at least $12.5M for Radio Shack at the 250,000 Novice level.

A side benefit to Radio Shack would be the generation of a bunch of new customers who are used to coming to their stores. If they put out a Novice rig at, say, $350, they would be able to generate another $85M or so in sales, bringing the whole project up to around $100M.

As long as the computer sales don't falter in their growth, Tandy will continue to have a healthy stock price. But perhaps, in view of the softness of the product through their lack of adequate software and with the impending invasion from Japan, it might just be prudent for Tandy to have a new project in the wings which can keep profits growing in case the computer line falters.

Radio Shack has tried several other fields for possible development into major consumer sales, but they have fallen through. Perhaps ham radio is one which would click. Between the ham clubs and local advertising and promotion to get in high school students, I think that 250,000 per year is not a difficult goal for such a program. That would only require one evening per week for the stores. Two evenings a week, average, would bring out 500,000 new hams a year. We might have to get real busy and develop some of the plans for coping with that number of hams if that came about.

Despite the seeming crowds on our ham bands today, the technical developments we see immediately ahead would enable us to cope with at least ten times as many hams as we have right now. It would be one of the best things to ever happen to amateur radio.

The classes would help to focus the attention of our country on the need for amateurs as a way to regain our lead in electronic technology. . .making ham radio and Radio Shack the heros. Perhaps in five to ten years the damage done by "Incentive Licensing" can be undone.

VIVA ARRL

Every now and then I meet a ham who really believes that I am anti-League. Gracious, nothing could be further from the truth! I have long been a steadfast and loyal supporter of this organization which is devoted to the relaying of messages by amateur radio. Indeed, where would our country be without this free message service?

Oh, I must admit to a bit of pique when some of the ideas which I have suggested to the League have been given short shrift. But these ideas were only for the purpose of improving their image and bringing more glory to amateur radio. For instance, I can only ascribe the refusal to institute the Singing Hamgram to the classical Not-Invented-Here mentality.

It stands to reason that if amateur radio relaying is ever going to be successful it is going to have to take cognizance of the competition and meet it with similar or better services. Older-timers will remember the triumphs of the past. What old-time ARRL member isn't moved to tears over the memory of the Postal Telegraph being forced out of business? I've got my 40-year membership pin and I'm pulling for us to topple Western Union. We've got 'em on the ropes, but we must keep up the pressure.

As an answer to those mentally retarded illiterates who insist that I am not 100% pro-ARRL, I pledge to find something positive to say about the organization. After looking over the situation carefully, I believe that I will be able to come up with a very positive statement along in June or July. This will take some research on my part, but it will be worth every minute of it if I can counter the calumny which has been spread by people who are trying to hurt *73 Magazine*.

AFRICAN POWER

While it sure would be nice to both perk up the action in the African countries with more hamming and to know that amateur radio is doing its thing for these countries by providing them with a reservoir of young hams who can then go on to being engineers and technicians . . .much as was done in Jordan, there are some special problems facing most African countries which have to be taken into consideration.

It is a fact that most African countries are paying heavily for their technical work to be done. They have to import European engineers and technicians at substantially higher salaries than would have to be paid for citizens. In many cases, where the country goes to the expense of sending its own citizens to the US or Europe for technical training, these people remain abroad since their opportunities are far better there than at home.

Amateur radio could solve a lot of that problem for these countries, if it were given a chance. The country would have to support the establishment of ham stations and ham study groups within their youth clubs. They would have, as did Jordan, to set up some people to make the rounds of these clubs and provide the technical training needed.

My friends in these countries assure me that there are teenagers in these countries with brains and the drive to go far in electronics, if only a ham program could be instituted. There is no shortage of the raw materi-

ARRL INTERNATIONAL DX CONTEST—PHONE

0000 GMT March 7 to 2400 GMT March 8

The ARRL-sponsored contest is open to all amateurs worldwide. Note that the basic contest format has been returned to that of 1979, with W/VE stations working the world and everybody else working W/VE stations only. The changes to single-band categories and the expanded awards program proved very popular and remain unchanged. Use all bands, 1.8 to 30 MHz.

Operating categories include single operator allband and single-band; multi-operator single transmitter or multi-transmitter; QRP single transmitter only with 10 Watts input or less (5 Watts output or less).

Your callsign must indicate your DXCC country (KL7XYZ/2 in NJ, FG0AAA/FS on St. Martin, etc.). One operator may not use more than one callsign from any given location during the contest period. The same station may be worked only once per band. No crossmode, crossband, or repeater contacts. Aeronautical and maritime mobile stations outside the USA and Canada may be worked for QSO credit only by W/VE stations. All transmitters and receivers must be located within a 500-meter-diameter circle, excluding directly-connected antennas. This prohibits the use of remote receiving installations. However, multi-operator stations may use spotting nets for multiplier hunting only.

EXCHANGE

W/VE stations (includes 48 contiguous United States and does not include Canadian islands of St. Paul and Sable) send RS and state/province. DX stations send RS and transmitting power as a 3-digit number.

SCORING

W/VE stations count 3 points per DX QSO. The multiplier is the sum of DXCC countries (except US and Canada) worked per band. DX stations score 3 points per W/VE QSO. The multiplier is the US states (except KL7 and KH6) and VE1-7, VO, and VE8/VY1 worked per band. Maximum of 57 per band. Final score is total QSO points times the total multiplier.

AWARDS

Various plaques and certificates to top scorers. Certificates to each DX entrant making more than 500 QSOs. ARRL-affiliated clubs compete for gavels on three levels: unlimited, medium, and local clubs. Details should have appeared in the January, 1981, *QST*.

ENTRIES:

All entrants are encouraged to use forms available from ARRL (include an SASE or one IRC). Logs should indicate times in GMT, bands, calls, and exchanges. Multipliers should be clearly marked in the log the first time worked. Entries with more than 500 QSOs must include cross-check sheets. All operators of multi-operator stations must be listed. Entries must be postmarked by April 7, 1981, and addressed to ARRL, 225 Main Street, Newington CT 06111. Any entries received after mid-July may not make *QST* listings. Usual entry conditions and disqualification criteria.

BOY SCOUT EXHIBITION STATION

The Playground Amateur Radio Club (PARC) of Fort Walton Beach, Florida, will operate a special event station at the 1981 Boy Scouts of America Choctawhatchee District Scout Exhibition. PARC members will operate station WB4SFU (Scouts For Unity) from 0000 to 2400 GMT on March 14, 1981. The station will be operating on 14290, 21370, and 28600 kHz on SSB. A special commemorative QSL card will be sent to those who QSL with an SASE. The QSL manager is PARC, c/o Joe Giangrosso WD4JZG, PO Box 3075, Fort Walton Beach FL 32548.

QCWA QSO PARTY—PHONE

0001 GMT March 14 to 2400 GMT March 15

Contacts with the same station on more than one band can be scored only once. Contacts made with "captive" stations, such as when operating in local nets, are not valid.

EXCHANGE:

QSO number, operator's name, and QCWA chapter identification (official number or name). Members not affiliated with a chapter should use "AL." If a member belongs to several chapters, then *one* must be chosen and used for the QSO Party. If desired, you may use one chapter for the CW Party and another one that you belong to for the Phone Party.

FREQUENCIES:

Any authorized amateur frequency is permissible. The following suggested frequencies have been selected to minimize interference to others:

3900-3930, 7230-7260, 14280-14310, 21350-21380, 28600-28630.

SCORING:

Each contact made with another QCWA member will count as a single point. Add up the contacts with QCWA members and then multiply this number by the number of chapters represented.

AWARDS:

Plaques for the top scorers; certificates will be given for the 2nd through 5th runners up. Standings and scores will be published in the *QCWA NEWS*, summer, 1981, issue.

ENTRIES:

Logs should include the following information: time (GMT), call, QSO numbers, name, chapter number or name, state or country. It is the responsibility of each contestant to provide a legible log (no carbon copies) and to list all claimed contacts. The total contacts for each page will be recorded at the bottom of each page. The total contacts for the Party should be recorded

at the top-right of the first page of the log. Log sheets will not be returned. Make sure you have correct postage when you mail your logs. Send logs no later than March 31, 1981, to: Pelican Chapter QCWA, Arthur M. Monsees W4BK, 1407 48th Avenue NE, St. Petersburg FL 33703. Separate logs and scores must be submitted for both the CW and Phone Parties. The decision of the Pelican Chapter of QCWA will be final with respect to scores and rules. In the event of errors or a disagreement, keep all details off the air and write either the Pelican Chapter or QCWA Headquarters.

Work as many QCWA members as possible and apply for the several Special QCWA Certificates which you have qualified for in the QCWA Parties: Worked 50 States, Worked 60 Chapters, Worked 100 Members, and Worked 500 Members.

1981 INTERNATIONAL SSTV CONTEST

Saturday, March 7, 1500 to 2300 GMT
Sunday, March 8, 1500 to 2400 GMT

SPONSOR — *73 Magazine*, Peterborough NH 03458 USA

OBJECT — To exchange SSTV pictures with as many stations in as many parts of the world as possible during the contest periods.

FREQUENCIES — All amateur frequencies between 3.5 and 29.7 MHz where SSTV is permitted.

EXCHANGE — Exchange of pictures must include callsign, RST report, and consecutive contact number starting with 001. FCC rules require a verbal exchange of callsigns for US stations. Do not include the contact number in the verbal exchange.

CREDITS — One (1) point for each station worked. A station may be worked once on each band for credit. One (1) point for each US state or Canadian province worked. Five (5) points for each country worked. Five (5) points for each continent worked. Each state, province, country, and continent may be counted only once for credit. Total score is the sum of all credits.

ENTRIES — Activity sheets should show station worked, state or province, country, continent, and band (80, 40, 20, 15, 10). Summary sheets should show number of stations worked, number of states and provinces worked, number of countries worked, number of continents worked, and total score. Entries become the property of the contest committee. Excessive discrepancies in a contest entry may cause disqualification. Contest entries must be postmarked no later than April 30, 1981. The decisions of the contest committee are final.

AWARDS — The top scorer will receive a certificate and a one year subscription to *73 Magazine*. Certificates will also be awarded to the station working the most countries and to the station working the most continents.

Send all entries to:
R. Brooks Kendall W1JKF
10 Stocker St.
Saugus MA 01906

or David Ingram K4TWJ
Eastwood Village, #1201 South
Rte. 11, Box 499
Birmingham AL 35210

DARC CORONA 10-METER RTTY CONTEST

1100 to 1700 GMT March 14

This is the first of four tests during the year sponsored by the DARC eV to promote RTTY activity on the 10-meter band. Each of the four tests is scored separately. Use the recommended portions of the 10-meter band.

EXCHANGE:

RST, QSO number, and name.

SCORING:

Each station can be contacted only once. Each completed two-way RTTY QSO is worth 1 point. Multipliers include the WAE and DXCC lists and each district in W/K, VE/VO, and VK. The final score is the total number of QSOs times the total multiplier.

AWARDS:

Plaques will be awarded to the leading stations in each class with a reasonable score present. Operating classes include: (1) class-A for single or multi-op and (2) class-B for SWLs.

ENTRIES:

Logs must contain name, call, and full address of participant. Also show class, times in GMT, exchange, and final score. SWLs apply to the rules accordingly. Logs must be received within 30 days after each test. Send all entries to: Klaus K. Zielski DF7FB, PO Box 1147, D-6455 Erlensee, West Germany.

The other contest periods are on May 10, September 26, and November 8, 1981.

SOUTH CAROLINA QSO PARTY

1700 GMT March 14 to 0500 GMT March 15
1500 to 2400 GMT March 15

The QSO party is again sponsored by the Colleton County Contestors. The same station may be worked on each band and mode. SC stations may work other in-state stations. Novice and Technician stations must sign /N or /T for identification purposes.

EXCHANGE:

RS(T) and state, province, country, or SC county.

SCORING:

SC stations score two points per QSO; SC Novice and Technicians score five points per QSO. Multiply QSO points by the number of SC counties + states + provinces + countries. All others score two points for each SC contact, five points if with a Novice or Technician in SC. Multiply total QSO points by the number of SC counties worked (46 max.).

FREQUENCIES:

PHONE—3900, 7260, 14300, 21360, 28600, 50.110, 144.2 (simplex—no repeaters!).

CW—1810, 3550, 3710, 7050, 7110, 14050, 21050, 21110, 28050, 28110.

AWARDS:

Certificates to top-scoring station in each SC county, state, province, and DX country. Also to top-scoring Novice and Technician in each SC county and each state.

ENTRIES:

Include a summary sheet with your entry showing scoring and other information. Mailing deadline is April 18, 1981, to: Colleton County Contestors, c/o Elliott Farrell, Jr. WA4YUU, PO Box 994, Walterboro SC 29488. Include a large SASE for a copy of the results.

ERAA QSO PARTY

1400 GMT March 14 to 0200 GMT March 15

The Edison Radio Amateurs' Association (ERAA) WA8SVA of southeastern Michigan will host a QSO party to commemorate ERRA's 40th anniversary. Those wishing to participate should exchange signal report and state with the ERAA QSO Party group. Phone operation only; suggested frequencies are 3930, 7240, 14300, 21400, 28800, 146.52 simplex, and 144.73/145.33 (ERRA repeater). The ERAA QSO Party group will be operating from Thomas Edison's first power station, Station A, in historic Greenfield Village, Dearborn, Michigan. QSL via WA8SVA, 12806 Royal Grand, Detroit MI 48239. Participants will receive a certificate by enclosing a business-sized SASE.

RTTY LOOP

Marc I. Leavey, M.D. WA3AJR
4006 Winlee Road
Randallstown MD 21133

Last month we took a look at the Microlog ATR-6800, one of the new breed of RTTY stations. This month shall be an examination of what it takes to put a unit like this on the air, and what operation itself is like.

To begin with, let me take a moment to describe the situation in the station when the ATR-6800 arrived. The station here is nothing fancy, consisting of basic equipment which may be found at many a ham's shack (see Fig. 1). The transmitter is a Heathkit® SB-401, with an SB-303 receiver. A SB-650 digital display makes readout of the receive frequency easy, although when in the RTTY mode the display is offset by the BFO frequency, in the 3-kHz range—makes things tough! Incoming RTTY signals are demodulated by a HAL ST-6, and normal printing is on an old Teletype® Model 15. Paper-tape equipment is in the loop, but not used too much. Keying of the transmitter is by the circuit described some time ago in *73*, off a magnetic reed relay in the loop.

In the interests of modernization, I will add that a 6800-based computer resides in the shack. By cabinet it is an SWTPC, but the guts are an amalgam of SWTPC, Smoke Signal Broadcasting, GIMIX, and Leavey Labs. A versatile RTTY program is often booted in to interface with the ST-6, and take the chores away from the Model 15.

Enter the ATR-6800! The unit is provided with an assortment of cables which already have the special connectors required attached to one end, and several common plugs to mate with many types of amateur equipment. In order to receive signals, the ATR-6800 must, of course, be provided with receiver output. Unlike many other units which only accept speaker audio, albeit the most common input provided, the Microlog will accept digital (TTL), RS-232, or audio, depending on the mode, and with Morse will even accept a hand key. Now, that's versatility. Nevertheless, I connected the audio output of the SB-303 to the ATR-6800. Connecting the RCA-type plug, which was provided, to the prewired cable was all of a five-minute job.

Again, a great variety of outputs is available, from grid-block compatible keying for Morse to RS-232 on Baudot and ASCII. I selected the standard AFSK tones, which I fed to the SB-401 through another phono plug. Connection to a scope is optional; the input and output are enough to get you on the air.

Turning the transmitter on produced an unpleasant surprise: The transmitter keyed and stayed on, no matter what the status of the ATR-6800. Some quick diagnostics revealed the problem. I was feeding the audio directly into the SB-401, and depending on the presence or absence of AFSK out to activate the transmitter through the VOX circuit in the transmitter. Unfortunately, the AFSK was always present, transmit or receive. The designers thought of this, however, and one quick cut and jump was done to set the unit up for the correct mode of operation.

I recommend that if you are purchasing one you should specify whether you want to use the audio out to key a VOX circuit. The change is not difficult—if you have a factory representative there to do it, as I did!

Now we scanned the dial looking for stations. Several were noted in the eighty- and twenty-meter bands, and most could be tuned with little difficulty. Lacking an external scope, the method of tuning is a bit primitive, at best. One light is provided, labeled as a "Tuning Indicator." This light goes on and off with FSK signals, only it takes quite a bit of practice to get it to flicker just right.

As another aid, a "reference tone" is available. This is an onboard speaker that sounds a tone when you are tuned fairly closely. Only problems are that in a noisy shack, with the speaker blaring, the low level from the small internal speaker is a bit hard to hear, and the triggering is again somewhat ambiguous. Certainly, using an inexpensive scope on the provided outputs makes tuning in signals much easier.

Prior to initiating a call, several memory buffers are available to be filled with callsigns, CW identifier, etc. Using the SHIFT, CONTROL, and ID keys, this can be done relatively quickly. It, again, takes some practice to remember some of the function codes, but they are well detailed in the manual. The end result is a closing identifier that gives the station call in RTTY and Morse, then automatically switches to receive.

After an hour or so of receiving and fooling around, we try to make a few contacts. Problems with the transmitter and receiver aside (it's not the Microlog's fault that the Heathkit RTTY position prevents linking the units together for transceive operation), we set up on frequency and call CQ. After a few calls, an answer sweeps across the ether—and ol' fumble fingers strikes.

You see, there is no button marked "transmit" or "receive" on the Microlog. To transmit, you send a SHIFT-KN; to receive, a CONTROL-SK (the key is actually marked SK/RTN). Now, if you send a CONTROL/KN, instead of a SHIFT-KN, you go to receive, instead of transmit, and clear the buffers. SHIFT-AR, on the other hand, will also go to receive, but only when the text buffer empties out, useful for typing ahead, and SHIFT-BT will switch to RTTY mode from, say, Morse, again when the text buffer is empty. I don't think a SHIFT-SK does anything special.

Confused? Well I was, and when I relayed some of this to Micrometer the answer I got was in the, "it makes *mistakes harder*" vein. It also makes smooth operation harder, guys! To illustrate, Fig. 2 is a summary of functions and their commands. One of the most obvious suggestions would be to label keytops with the SHIFTed or CONTROL function, just as they are now labeled with special Morse characters.

One of the advertised features of the ATR-6800 is that it can be hooked up to a computer to act as a terminal. It can be, but there are some problems. First of all, the normal 40- character-by-24-line display is a bit small for most work. Further, the system is set up so that lowercase is displayed when the shift key is depressed, backwards from most true terminals (modified TRS-80s excepted). Moreover, several of the commonly used symbols, such as brackets, up-arrow, and backslash, are not represented, and lowercase letters are a bit abnormal, with raised "p", "q", "g", and "y".

What is more intriguing is to use the ATR-6800 as a standalone computer itself, a possibility that is on the horizon. Several programs are currently available which allow the unit to output SSTV as three lines of six characters per line, function as a mailbox, autostart/WRU, or several other modes. All of these programs are available on tape, and load from a conven-

LETTERS

R/CERS UNITE

I wish to express some opinions in regard to the recent FCC deregulation of the 6-meter band.

In a band use proposal, In Looking West, I was shocked to note the complete lack of consideration given to the radio-control enthusiast.

As I am sure you know, 53.1, 53.2, 53.3, 53.4, and 53.5 MHz are actively used by amateur radio operators for R/C purposes. Commercial as well as kit equipment is manufactured using these standard R/C frequencies.

Bill Pasternak WA6ITF mentioned in one of his follow-up reports that few if any negative comments were received by him regarding the 6-meter band proposal. Since these 6-meter frequencies are used by amateurs in R/C clubs throughout the United States, a change of this sort would not be welcome.

Further, the Academy of Model Aeronautics, the major R/C organization in the United States, also recognizes the present 6-meter frequencies as standard amateur assignment. I recommend that amateurs not interested in R/C work at least consider those that are.

It is unfortunate that many amateurs interested in R/C do not have interests in other modes of emission. This being the case, it is difficult to find out what is going on and what is being proposed. But, when we think about it for a minute: When was the last time any major amateur publication had *any* coverage on radio control?

Norman W. Pedersen KB6KQ
Bellflower CA

HAVE A STROKE!

This letter is addressed to all the kooks who have nothing better to do than QRM the traffic nets.

On August 21, 1980, my OM, W1GMA, suffered a massive stroke at 6:00 am Costa Rica time. Living way out in the country, we do not have a telephone. None of our near neighbors has a phone. It is four miles by road to the nearest phone.

My husband, "Doc," is a large man and I was unable to move him from the bathroom floor where he was unconscious. I hastily threw blankets over him to keep him warm and ran to the ham shack. I called In a triple break on 14313 where Dick KV4IJ was net control.

Dick said, "The person calling break break break. . . Do you have an emergency?"

I said, "You better believe it, Dick."

I identified and said that I thought my husband had just had a stroke and I had no phone. Could he raise someone in Costa Rica to get an ambulance for me? I gave instructions for the way to my home and within a half hour TI4FHC arrived followed by an ambulance.

This, my friends, is what ham radio is all about! Talk about service? I probably couldn't have done so well with a phone with my lousy Spanish.

I regret that the stroke was so massive that there has been little hope that I will ever regain the beautiful man I had the day before, but he is now at Walter Reed Army Medical Center and getting the best possible therapy. I have returned to Costa Rica temporarily, after a month in Washington. I will return to the states from time to time to check on his progress. When he is well enough, we will both return here to live the lovely life we have.

My profound gratitude to the 14313 nets, to TI4FHC, and to all who assisted in this ordeal. To the K4 who insists on operating ½ kHz above the net: *HAVE A STROKE!*

Kayla Hale W1EMV/TI5
Alajuela, Costa Rica

APPLIANCE USERS

With regard to the letter from Alan Davis KB7HM and Wayne's reply, "Let's hear it for the code-free, theory-free license," December, 1980, *73 Magazine,* I must agree that most modern day hams are appliance users. With the state-of-the-art what it is, how many hams have the laboratory test equipment to produce commercial-quality ham equipment? It is cheaper to purchase the store-bought equipment, even if one could locate the components to build good ham equipment.

However, I cannot quite go along with the idea of the code-free, theory-free ham license. Eleven meters speaks against such a concept. Throughout the years, hams have been admired and respected for the effort that they were willing to put forth in order to obtain a ham license. Most hams do not regret having expended that time and effort. Of course, there always has been, and always will be those who want something for nothing, and this type of person keeps on demanding more. As a compromise to these something-for-nothing demands, I would like to offer the following suggestions.

Leave the frequency allocations for both CW and phone exactly as they stand at the present time. Those who wish to operate nothing but phone could be granted a code-free/theory-free license, which would allow them full phone privileges in all presently established phone bands. This could be handled in the same manner CB licenses are handled.

Those people who desire to upgrade their status from appliance user to radio operator and still retain full phone privileges would be required to pass the following code tests:

5-wpm code speed for operation in the Novice class CW bands.

13-wpm code speed for operation in the General class CW bands.

15-wpm code speed for operation in the Advanced class CW bands.

20-wpm code speed for operation in the Extra class CW bands.

All code tests except the 20-wpm test to be given by a certified volunteer examiner, being at least one grade above the person being examined. The 20-wpm code test should be administered only at a field office of the FCC. This proposition would take a lot of the work load off of the FCC and give them more time and money to chase rule violators, jammers, bootleggers, etc.

Many people who would like to become hams but have never been willing to buckle down and earn the license will probably find this stupid idea very appealing. However, I doubt that very many already licensed hams will find much appeal in this idea.

I know that if this proposal was to be carried out, it would not cure 100% of ham radio's ailments. However, it would give the freeloaders something for nothing and still leave something to be gained for those who were willing to expend a little bit of time and effort. Regardless of what a few people may try to lead us to believe, CW is by no means dead, and it still has its place in the radio hobby.

TREASURE ISLAND

Wayne, I enjoy your magazine now as I have for 15 years. No, your editorials are not too long for some of us, the mixture of nostalgia and modern topics blends into an interesting few minutes of reading.

Yes, at Treasure isle in 1942-43, I did carve W6ECB into one of the desks that you apparently sat in at a later date and I was amazed that you copied several of the calls to remember 30 or so years later in one of your writings.

Like you, I joined the Navy in early 1942, took an accelerated EE (without calculus) course at the University of Houston, on to T.I., then to New London for sub school where I was detained for 18 months to teach code to some of the "90-day wonders"! I went to the South Pacific on the *Green Hornet* AS-23 sub tender, and had a few rides on the *USS Archer Fish* before ending the war in the Subic Bay! We heard stories about the *USS Drum* but we also had our hands full in the China Seas and I can't remember feeling necessarily sorry for you!

Amateur radio (W6ECB, licensed in 1934) has given me many friends, a Navy way of life, many hours of pleasure, many dollars spent, and many (40) years of married bliss (because I was home).

I agree that we must get more

AWARDS

Bill Gosney WB7BFK
Micro-80, Inc.
2665 North Busby Road
Oak Harbor WA 98277

This week I received a very nice letter from Lynn Hansen KA0CLQ who represents the Central Iowa Radio Amateur Club. In her letter Lynn provided me with the details of their new award entitled the Tallcorn DX Award.

TALLCORN DX AWARD

Applicants wishing to meet the requirements of this DX award program must confirm contact with three or more members of the Central Iowa Radio Amateur Club. While there are no band or mode restrictions, there is the need for complete and accurate logbook information for each contact made. This DX award is issued free, but, applicants are asked to submit a large business-sized SASE and 50 cents to defray cost of postage.

The members of the Central Iowa Radio Amateur Club are active in various modes of operation. You may find them on CW, phone, RTTY, and SSTV. Should you wish a single-band or specific mode qualification, I suggest you write the club directly and arrange a roster of the membership and at the same time arrange a schedule with a few of the operators.

Inquiries may be directed to the Central Iowa Radio Amateur Club, PO Box 39, Marshalltown IA 50158.

WORKED ALL LYNCHBURG LADIES AWARD

The Lynchburg Amateur Radio Club announces the availability of a new piece of "wall paper." This award, the Worked All Lynchburg Ladies Award, may be earned by working three YL members of the Lynchburg Amateur Radio Club. If you think that's difficult, sympathize with Lynchburg area amateurs. They must work five Lynchburg Ladies on modes other than repeater operation.

This award is available at no charge. The applicant should submit the usual logbook information and it would be advisable to enclose a small donation to offset any postage expense. Submit your entry to Rachel Bush, 1109 Dandridge Drive, Lynchburg VA 24501.

73 MAGAZINE AWARDS PORTFOLIO

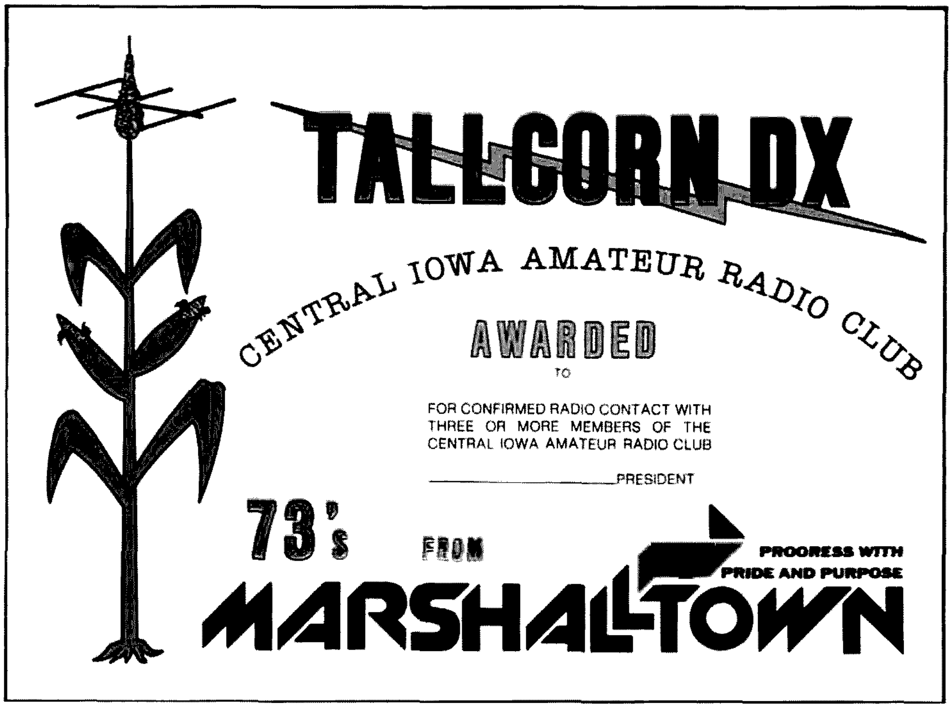
If readers are still seeking copies of our detailed awards program, find your September and October, 1980, back issues, as all nineteen award incentives for both the domestic and DX award hunters are listed there. Each was designed to be the ultimate in operating achievement. Back issues of the September and October, 1980, editions are available by writing or calling our Bookstore.

SWISS BEAR AWARD

The New Bern Amateur Radio Club is sponsoring the Swiss Bear Award. This award will be given for working 3 different amateur stations in the New Bern area within the period of October 23, 1980, and October 23, 1981.

Extracts from logs for QSOs during this period, along with an SASE, or in case of DX stations two IRCs, should be sent to: New Bern Amateur Radio Club, Inc., PO Box 2483, New Bern NC 28560.

The Award consists of a certificate depicting the Swiss Bear, symbol of both Bern, Switzerland, and New Bern, North Carolina, and stating that the station has met the requirements for this award.



Glancing at my wall full of DX awards, it's staggering how much investment is represented just in postage costs to gather the required QSL cards to qualify for these achievements. Just as a guesstimate, I must have spent well over a thousand dollars in IRCs and greenbacks over the past three or four years. Well, the expenses for stateside confirmation aren't much better. Finally, however, we are pleased to learn of a new stateside QSL service that promises to relieve much of the formal expense in getting the job done. Known as the US OSL Service, it is founded and managed by N7BMY and KB7JW, both of Mulino, Oregon.

US QSL SERVICE

Can you believe it? One address for all your domestic QSLing, both incoming and outgoing, for all ten call districts, including Alaska and Hawaii? Unbelievable, you say!

Available now to all licensed amateurs in all fifty states, the service uses professional file clerks to ensure accurate, speedy, and ongoing QSL handling. Emphasis is placed on hiring the disabled, people who want to be self-sufficient but need an opportunity to do so. The service asks for a very minimal 25¢ for each incoming batch of up to 20 QSL cards. This covers wages and operating costs incurred in processing the correspondence.

In comparison, to show how the service can be of benefit to all of us, consider the present cost of sending twenty QSL cards. At 10¢ each, you'd spend $2.00 in postage alone. In addition, you have to look up all twenty addresses, which can be difficult, expensive, and more or less frustrating after you go through a stack of cards. Chances are some of the contacts were new calls, not yet listed in the *Callbooks*, or perhaps a new address has not yet been inserted in the present address listing. Need we say more? Now, to send these same QSL cards to the US QSL Service costs you up to 85¢ (30¢ postage, 30¢ on two SASEs, and 25¢ handling charge). Think of it this way: You have to only lick three or four stamps instead of 20!

Who are the founders and

REVIEW

YAESU FT-707 HF TRANSCEIVER

Checked any equipment prices lately? When it comes to equipment, hams have never been able to get so much quality and performance for so little money. The new Yaesu FT-707 HF transceiver is a good example. It offers features and performance equal or superior to top-dollar rigs of a few years ago. Today, the FT-707 is one of Yaesu's least expensive rigs. It says a lot for the state of the art when a relatively inexpensive transceiver offers the features this new Yaesu does. Let's take a good look at it.

The FT-707 is similar in size to rigs like the Kenwood TS-120S, the Icom IC-701, and the Atlas 150. It covers all present and planned bands between 80 and 10 meters, including the new WARC bands. The bandswitch itself has a very precise feel, clicking smoothly into place, rather than thunking noisily as do bandswitches on many other rigs. Just to the right of the bandswitch is the vfo knob which also seems to have been engineered for the proper feel.

Yes, the 707 has the digital frequency readout that we now take for granted on high quality gear, but it also offers a well-calibrated and easy-to-read analog display, useful when the companion external vfo and memory unit is in use. Just above the vfo knob are four status LEDs, telling which vfo is in use, if the marker generator is switched on or off, and whether a crystal-controlled frequency has been selected.

The Yaesu 707 line.

The display that attracts the most attention is the front-panel meter, which is a multi-segment bar-type LED display. The lower-value segments glow green, higher readings are yellow, and the highest readings show red. This display does more than impress your friends. It allows you to keep tabs on signal strength, relative power output, and alc level.

Whether LED displays are really better than regular meters has been a subject of much debate lately. For the purposes it serves on the 707, the LED display works admirably, particulary in mobile installations where a traditional meter would be difficult to read while maintaining safe operation of a vehicle.

Other goodies on the front panel include an effective noise blanker, an i-f shift control, a 25-kHz marker generator, VOX controls, an RIT control, and an eight-conductor microphone plug that permits scanning from the mike if the rig is equipped with the FV-707DM external vfo. Also worth mentioning are the rf gain control, fast/slow agc switch, and fixed-channel operation switch. Along with the usual antenna, key, and power connectors, the rear panel sports an rf output jack for use with transverters, and sockets for the external vfo and accessories. Yaesu has managed to squeeze a lot into a small package!

Hands-On

Unpacking a new rig and wiring it into the ham station is an activity that most hams enjoy, and the hams at *73* are no exception! We had the 707 and its accessories wired to ground, power, and our Alpha 374 amplifier in no time at all. The human engineering that went into this rig is obvious; few other rigs we've seen have interfaced with such ease. Like the Icom 701, this rig has a relay box that is necessary if you plan to use both an amplifier and the external vfo. Even if you will only use an amplifier, this accessory is worth purchasing; it makes interfacing much simpler.

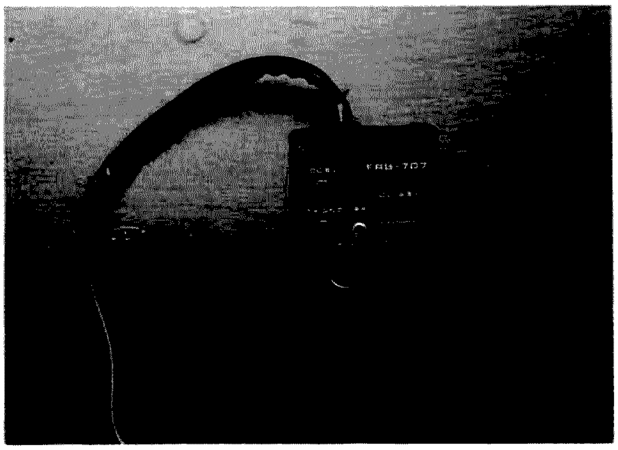
As soon as the rig was in place, the manual read, and basic operating parameters checked, we put the rig through the infamous *73* wringer. We connected the 707 to our Drake DL-1000 dummy load and checked the power output in the CW mode. A Bird wattmeter confirmed Yaesu's claim of full output on all bands. Our sample put out 100 Watts ±10%, with highest output on 80 and 20 meters, and lowest on 40 and 10 meters. Several other rigs we have tested have dropped by as much as 50% on 10 meters. The Yaesu's performance is admirable.

While we had the 707 on the dummy load, we checked out Yaesu's protection circuits. Like most of its solid-state brethren, the FT-707 finals are protected with a high swr shutdown device. As the swr climbs, the rig automatically reduces power to protect itself. Many rigs carry this to a fault, and almost any swr at all on the line causes a significant reduction in power output.

Yaesu's engineers seem well acquainted with the real world, and they designed the 707 to shut down only slightly at 2:1 or lower. Limiting action is heavy at 3:1 or higher, shutting the output down to a small percentage of its capabilities. This is a sensible arrangement, since many hams operate their equipment into transmission lines with moderate standing wave ratios. Further, a defect in the feedline or an improperly set coax switch will probably cause the swr to go much higher than 2:1. In short, the FT-707's ability to protect its expensive output devices is hardly curtailed, yet the annoying side effects of such protection have been mercifully banished.

Other protection circuits include a temperature-controlled fan and a thermal shutdown circuit. The instruction manual recommends a key-down period of no longer than 30 seconds, but we wanted to see how well the 707 protects itself, so we left it key-down for several minutes. Sure enough, the fan came on after a minute or so, and continued to run after switching over to receive. Having the fan run until the finals cool off is an excellent idea. Unfortunately, our unit was cursed with a noisy fan which rattled in a most aggravating manner. This was a problem peculiar to our sample, and it shouldn't be encountered in other 707s.

During normal operation the fan never came on at all, confirming that the fan is only a safety feature; the rig has



The FRB-707 relay box.

enough heat-sink area to dissipate the heat produced in normal operation. We never pushed the finals hard enough during any of our tests to cycle the thermal shutdown device.

On the Air

Operating the 707 is a pleasant and rewarding experience. Its no-tune-up design permits instant operation. Adjust the mike gain on SSB or the carrier level for CW to proper levels as indicated on the front-panel meter, and you are ready to go! Hams who have never operated a solid-state rig are in for an agreeable surprise.

While searching for DX on 20 meters one night, I noticed that tuning in individual signals seemed relatively easy with the 707. Sure enough, when compared to several other popular rigs gracing the *73* ham shack, the 707 came up with noticeably wider bandspread. The only rig in our possession that performed better in this respect was the Icom IC-701, whose digital tuning gives it an unfair advantage.

Selectivity is very good, with two eight-pole i-f filters standard. 600-Hz and 300-Hz CW filters are available as options. The 350-Hz filter was installed in our unit; switching it in provides a startling reduction in interference. Hams who enjoy CW (and Novices in particular) should consider a sharp CW filter necessary equipment for any receiver. The i-f width control is active on both CW and SSB, with performance comparable to other rigs having a similar control.

If you have always yearned for a rig that would allow you to check into an 80-meter AM phone net, or check out the action on 10-meter AM, you are reading the right review! Seriously, with the high level of interest in converted CB equipment, the AM feature allows entry into a world that is denied to owners of many other modern transceivers.

The quality of the manual also bears mention. For whatever reason, manuals for Japanese ham gear do not enjoy a particularly good reputation among hams in the USA. Well, I'm pleased to report that this is one of the good ones. While obviously written by someone for whom English is a second language, the instructions are perfectly clear and understandable.

Servicing information is pretty good, too. We are provided with complete schematics, block diagrams, and a very good circuit description. For those with access to good basic test equipment, there is a section on maintenance and alignment. We haven't seen too many manuals better than this for any transceiver, whatever its country of origin.

As with any piece of equipment, we found a couple of things we'd like to see Yaesu change; in this case, serious complaints were notably absent. The adjustment for sidetone level can't be reached without popping the top cover off—we'd like to see it located where it can be readjusted easily, perhaps on the back panel. It also would be nice if the 707 included some sort of a speech processor. Yes, I know that they are often misused, but there are times when a processor is useful. These are very minor problems, and I almost wish I could find more to gripe about, but I can't!

Power Supply

The matching FP-707 12-volt power supply would be a welcome addition to any shack. Regulation is very tight even under full load and the supply runs quite cool. (Except when testing the rig's protection circuits!) There is one feature of this supply that I was very pleased to discover. When you spend $150 on a power supply, you want to be able to get a lot of use out of it. Most supplies designed to match a specific rig have a special cable permanently attached and there is no way to use the supply to power anything else unless you tear into the case and add your own connectors. Yaesu has solved this aggravating problem by putting two multi-way connectors on the back of the supply, in addition to the cable that goes to the FT-707. These connectors are in the main output circuit and can provide the full supply current output, which is 20 Amps intermittent. Thanks, Yaesu! The power supply is also provided with a front-facing speaker, which performs well for a speaker of its size.

FV-707DM External Vfo

The FV-707 is a truly unique accessory; it changes the whole character of the rig. It resembles a traditional remote vfo in that it allows split-frequency operation, but there the resemblance ends. Measuring only one inch high, the FV-707 is designed to fit underneath the rig rather than beside it, and once installed it seems to become part of the rig itself. The FV-707 can be programmed to store 12 frequencies in its internal memories. Install two AA cells and those frequencies will be held for a year, even when power is turned off! This eliminates the need to buy crystals for often-used frequencies, and it allows an incredible flexibility of operation.

If you are a DX hound, you can scan up and down the band, searching for pileups, and program the frequency of a plieup into each memory, to be recalled later at your whim. If nets are more your cup of tea, the FV-707 will help you keep track of those as well. Indeed, the uses for these memories are limited only by your imagination!

The FV-707 also allows you to scan up and down the band electronically. On the front of the unit are three buttons, marked Up, Down, and Fast. The first two are self-explanatory, and the Fast button works in conjunction with the other two. Normal scan rate is one kHz per second; push the Fast button at the same time as the Up or Down button and the rate increases to 10 kHz per second. With the optional YM-35 microphone, frequency scanning can be accomplished in the same manner using switches mounted on top of the microphone.

FC-707 Antenna Tuner

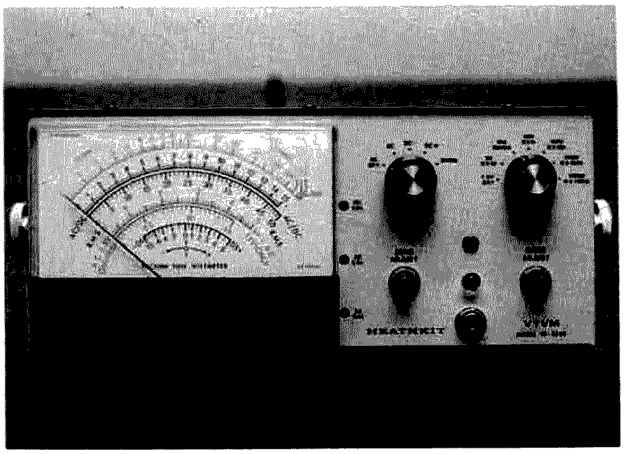
Designed specifically to complement the FT-707, the matching antenna tuner is a compelling little box. Once you have an FT-707 in your possession, the matching tuner is hard to resist. It sports a lighted meter that keeps track of power output with reasonable accuracy, as well as serving as an swr meter. An unusual but extremely handy feature of this tuner is the built-in dummy load, switch-selectable from the front panel.

As far as the actual tuning circuit goes, it is important to realize from the start that this tuner doesn't intend to compete with the larger and much more expensive tuners on the market. Maximum power-handling capability is 150 Watts, and the tuner will only tune coax lines; there is no provision for random-wire tuning.

Still, the tuner performs its intended job well, which is reducing swr on coax lines. Just for fun, we tried tuning up a 15-meter dipole on 40 and 10 meters, and the FC-707 handled the job easily. Naturally, such a lash-up didn't work very well, but it did show off the tuner's capabilities! This little tuner should serve well in both mobile and home installations.

Conclusions

Either on its own, or with its accessories, the Yaesu FT-707 is a truly competent piece of equipment. If you are a compulsive knob twirler, you'll find the digital features of the external vfo impossible to resist. If your quest is for solid performance on both SSB and CW, the 707 offers that, too. Its extremely compact dimensions make it an obvious choice for mobile installations, yet the front-panel layout



Heathkit's IM-5228 VTVM.

is such that it will be just as comfortable in a home station. If you have any interest in the new generation of compact, solid-state transceivers, this new Yaesu deserves your attention.

HEATHKIT® MODEL IM-5228 VTVM

When I talk to hams who are thinking of buying a test meter, they invariably seem determined to get one of the fancy new digital meters. Now don't get me wrong, I don't have anything against digital meters; it's just that they aren't necessarily the best meter for everybody, particularly if the budget only allows for one meter. Digital meters are not much help when you are trying to interpret a fluctuating reading, and, of course, they tend to be more expensive then a comparable analog meter.

Recently, while shopping for a new meter for the *73* ham shack, I came across an old friend, the Heathkit IM-5228 VTVM. This VTVM is hardly new to the market; in fact, I think it has been around a lot longer than I have! But that's just what makes it interesting. After all these years, it's still one of the best test equipment values on the market.

The 5228 is a bench-type VTVM. It comes with a gimbled swivel mount that allows easy reading of the meter, no matter where you place the VTVM. A slightly more compact version of the same VTVM is available from Heath for 10 dollars less. Since the bench unit has all its controls on the front panel and also has a larger meter movement, we opted for that model.

Kantronics' Varifilter.

The 5228 measures dc and ac volts and Ohms, and does so on enough scales to allow easy interpretation of any reading. I won't bore you by repeating all the specs here, since they're available in any Heathkit catalog, but I'll list a few to give you an idea of this meter's parameters.

The voltmeter section's ranges extend from 1.5 volts full-scale up to 1500 volts full-scale in seven ranges each for ac and dc. Maximum voltage capability can be extended to 30 kV with an inexpensive accessory probe. Input resistance is 11 megohms on all ranges, permitting accurate in-circuit tests without loading things down. The ohmmeter section will measure 0.1 Ohm to 1000 megohms in six different ranges.

The IM-5228 is capable of extremely accurate measurements, but final accuracy depends on how carefully the kit-builder calibrates his unit. Any test instrument will need recalibration from time to time, and the Heathkit people are quick to point out that one of the advantages of kit-built instruments is the owner's familiarity with the unit. This familiarity encourages the owner to periodically check the accuracy of his meter and align it when necessary, instead of blindly hoping that the factory calibration is still good.

The basic $69.95 kit uses two tubes, which means that the VTVM must be warmed up before use. A conversion kit is available which replaces the vacuum tubes with solid-state devices. We couldn't resist that convenience, so we ordered the conversion kit at the same time as the VTVM.

Construction

Assembly was straightforward and enjoyable. As is usual with Heathkit products, the instructions were clear and easy to follow. Parts identification was easy with the life-sized pictorial provided. The VTVM took about fourteen and a half hours to put together, working at a leisurely pace.

A few minor points should be kept in mind during assembly. Be aware that when directions indicate that a certain number of wires must be present at a soldering point, any wire passing through that point is counted twice: once entering and once leaving. Realizing this may save you a frantic search for something else to add to that connection!

The hookup wire provided was only just enough to do the job. If you cut your leads too long, you may run out. Also, the wire provided was all the same color. Different colors would have made it easier to check connections. Only one error was discovered in our assembly manual: On page 18, wires from lug 4, not lug 3, are to be left free.

It was extremely satisfying to find the VTVM working perfectly the first time it was plugged in. However, the solid-state modification was yet to come. If you plan to install this modification, it is simplest to do it during the initial assembly. The installation is not complicated, but it does require the desoldering and removal of several components. The modification took only a few minutes and the VTVM acquired no problems along with its new solid-state devices. Again, the unit worked immediately upon being plugged in! Construction was easy and the instructions were good. Even a novice kit-builder should have no problems with this one!

The Heathkit IM-5228 VTVM is an old friend in an attractive new cabinet. Hams looking for a high-quality but reasonably-priced voltage and resistance meter will find that this meter still represents one of the best values on the market.

Additional information is available from the *Heath Company, Benton Harbor MI 49022*. Reader Service number 486.

KANTRONICS VARIFILTER

If you've never used an active audio filter to aid reception of signals, you ought to try the Kantronics Varifilter to improve your listening pleasure. What is a Varifilter? Good question. it's a variable filter with variable frequency and bandwidth, and it allows you to select a peak or a notch mode.

Suppose you are an avid CW operator who likes to dig out the weak ones in a pileup. Maybe your receiver is not quite up to par in terms of its i-f selectivity, and you're limited to a minimum bandwidth of, say, 800 cycles. If the big guns also happen to be trying to work the same station you are and their S9+ signals

OSCAR ORBITS

Courtesy of AMSAT

The OSCAR satellites are subject to atmospheric drag, of course, and the present period of intense solar activity has accentuated the problem. During this period, our sun has been expelling huge numbers of charged particles, some of which find their way into the Earth's upper atmosphere, increasing the density (and thus the drag) there. It is through this region that the OSCARs must pass. OSCAR 8, in a lower orbit than OSCAR 7, is the more seriously affected of the two.

If the drag factor is not considered when OSCAR calculations are performed, long-range orbital projections will be in error. For example, by the end of 1979, OSCAR 8 was more than 20 minutes ahead of some published schedules. The nature of orbital mechanics is such that extra drag on a satellite causes it to move into a lower orbit, resulting in a shorter orbital period. Thus, the satellite arrives above a given Earthbound location earlier than predicted.

Using data supplied to us by Dr. Thomas A. Clark W3IWI of AMSAT, the equatorial crossing tables shown here were generated with the aid of a TRS-80™ microcomputer. The tables take into account the effects of atmospheric drag and should be in error by a few seconds at most.

The listed data tells you the time and place that OSCAR 7 and OSCAR 8 cross the equator in an ascending orbit for the first time each day. To calculate successive OSCAR 7 orbits, make a list of the first orbit number and the next twelve orbits for that day. List the time of the first orbit. Each successive orbit is 115 minutes later (two hours less five minutes). The chart gives the longitude of the day's first ascending (northbound) equatorial crossing. Add 29° for each succeeding orbit. When OSCAR is ascending on the other side of the world from you, it will descend over you. To find the equatorial descending longitude, subtract 166° from the ascending longitude. To find the time OSCAR 7 passes the North Pole, add 29 minutes to the time it passes the equator. You should be able to hear OSCAR 7 when it is within 45 degrees of you. The easiest way to determine if OSCAR is above the horizon (and thus within range) at your location is to take a globe and draw a circle with a radius of 2450 miles (4000 kilometers) from your QTH. If OSCAR passes above that circle, you should be able to hear it. If it passes right overhead, you should hear it for about 24 minutes total. OSCAR 7 will pass an imaginary line drawn from San Francisco to Norfolk about 12 minutes after passing the equator. Add about a minute for each 200 miles that you live north of this line. If OSCAR passes 15° east or west of you, add another minute; at 30°, three minutes; at 45°, ten minutes. Mode A: 145.85-.95 MHz uplink, 29.4-29.5 MHz downlink, beacon at 29.502 MHz. Mode B: 432.125-.175 MHz uplink, 145.975-.925 MHz downlink, beacon at 145.972 MHz.

At press time, OSCAR 7 was scheduled to be in Mode A on odd numbered days of the year and in Mode B on even numbered days. Monday is QRP day on OSCAR 7, while Wednesdays are set aside for experiments and are not available for use.

OSCAR 8 calculations are similar to those for OSCAR 7, with some important exceptions. Instead of making 13 orbits each day, OSCAR 8 makes 14 orbits during each 24-hour period. The orbital period of OSCAR 8 is therefore somewhat shorter: 103 minutes.

To calculate successive OSCAR 8 orbits, make a list of the first orbit number (from the OSCAR 8 chart) and the next thirteen orbits for that day. List the time of the first orbit. Each successive orbit is then 103 minutes later. The chart gives the longitude of the day's first ascending equatorial crossing. Add 26° for each succeeding orbit. To find the time OSCAR 8 passes the North Pole, add 26 minutes to the time it crosses the equator. OSCAR 8 will cross the imaginary San Francisco-to-Norfolk line about 11 minutes after crossing the equator. Mode A: 145.85-.95 MHz uplink, 29.4-29.50 MHz downlink, beacon at 29.40 MHz. Mode J: 145.90-146.00 MHz uplink, 435.20-435.10 MHz downlink, beacon on 435.090 MHz.

OSCAR 8 is in Mode A on Mondays and Thursdays, Mode J on Saturdays and Sundays, and both modes simultaneously on Tuesdays and Fridays. As with OSCAR 7, Wednesdays are reserved for experiments.

[FCC 80-634]

Petition for Reconsideration of Academy of Model Aeronautics Concerning Interpretation of Amateur Radio Service Rules To Allow a Nonlicensed Person To Operate an Amateur Radio Station To Control Model Aircraft

AGENCY: Federal Communications Commission.

ACTION: Interpretation of rule.

SUMMARY: The Commission's staff was asked to rule on the question as to whether a person not holding an amateur radio license could operate an amateur radio station to control model aircraft. The staff ruled that § 97.79(d) did not permit an amateur radio station to be operated by an unlicensed person for the purpose of controlling model aircraft since such use constitutes one-way transmission. The basis for the ruling was an interpretation of § 97.79(d) which permits unlicensed persons to participate in two-way amateur radio communications under the supervision of a control operator, but not one-way communications. The Academy of Model Aeronautics petitioned for review of this ruling by the full Commission. The Commission *en banc* affirmed the staff's interpretation.

ADDRESS: Federal Communications Commission, Washington, D.C. 20554.

FOR FURTHER INFORMATION CONTACT: Maurice J. DePont, (202) 254-6884.

SUPPLEMENTARY INFORMATION:

Adopted: November 6, 1980.

Released: November 21, 1980.

By the Commission:

1. The Commission received a letter, dated April 10, 1979, from Mr. Francis E. Morris of San Diego, California, inquiring whether a person not holding an amateur radio license could operate an amateur radio station to control model aircraft. By reply letter of May 18, 1979, Mr. Morris was advised that this was not permissible under Part 97 of our rules. The basis for the ruling was an interpretation of § 97.79(d) which permits unlicensed persons to participate in two-way amateur radio communications under the supervision of a control operator. The Commission's staff ruled that § 97.79(d) did not permit an amateur radio station to be operated by an unlicensed person for the purpose of controlling model aircraft since such use constitutes one-way transmission.

2. The Academy of Model Aeronautics (AMA), the petitioner in this proceeding, learned of the staff's letter to Mr. Morris. On August 27, 1979, AMA requested the Private Radio Bureau (Bureau) to reconsider its interpretation of Rule § 97.79(d). The staff did reconsider the ruling, and on October 15, 1979, advised AMA, through its attorney, Jack R. Smith, that the communications referred to in § 97.79(d) are meant to be two-way communications. The staff further advised AMA that the provisions of Part 97, unlike the Part 95 Radio Control Service Rules, did not extend operating privileges to non-licensed persons to control model aircraft. It is from this decision that the petitioner, AMA, now seeks review by the Commission *en banc*.

3. In its Petition for Review, filed November 14, 1979, petitioner presents three questions:

(a) Whether the Bureau erred in its construction of the term "third party"?

(b) Whether the Bureau improperly interpreted the Part 97 Rules in holding that the radio control provisions were not parallel in all respects to the Radio Control (R/C) Service Rules?

(c) Whether the Bureau's interpretation of "third party" is inconsistent with other Part 97 rules and with long-recognized Amateur practice?

4. At the outset, it will be useful to restate the principal issue in this proceeding. The question is whether or not a person, who is not a licensed amateur radio operator, should be permitted to operate an amateur radio station for the purpose of controlling a model aircraft. It is in this context that we believe that the matter should be addressed. It should also be noted that the Amateur Radio Service and the Radio Control Service are essentially different. The Amateur Radio Service is for technically-inclined persons who wish to learn about and experiment with radio communications equipment and operating techniques. On the other hand, the Radio Control Service is for anyone, whether technically inclined or not, who wishes to use radio for controlling a remote object.

5. One of the fundamental purposes of the Amateur radio service is the recognition and enhancement of the value of the service to the public as a voluntary noncommercial communication service. In furtherance of this aim, a licensed amateur operator may permit a non-licensed person, i.e., a third party, to participate in amateur radio communications from his station, provided that a control operator is present and continuously monitors and supervises the radio communication to insure compliance with the rules. An illustration of this type of third-party traffic is where United States military personnel stationed overseas, who are not amateur operators, are enabled to converse with their families back home via a two-way Amateur radio hook-up. To effect such communications, the countries involved must have assented to third-party traffic and licensed Amateur radio operators must be in control of the respective transmitting and receiving amateur radio stations. It is in this light that the the term "any third party" referred to in § 97.79(d) must be understood.[1] The resultant communications then become the "third-party traffic" which we have defined in § 97.3 (v) as:

> Amateur radio communication by or under the supervision of the control operator *at an amateur radio station to another amateur radio station* on behalf of anyone other than the control operator. (Emphasis supplied.)

Contrary to petitioner's assertion that § 97.79(d) is a broader section than § 97.3(v) and that it defines the scope of permissible participation by non-licensees in amateur communications, those two sections, as well as § 97.114[2] which specifies the conditions under which third-party traffic may be sent, are all inter-related and were in no way intended to provide for the non-licensed amateur communications which the petitioner desires. To hold that the third person referred to in § 97.79(d) includes a non-licensed person engaging in one-way communications to control a remote object is to strain for an interpretation of the rule to fit the petitioner's wish. Worse, it is yet another instance of chipping away at the basic requirement that only licensed operators be permitted to operate amateur radio stations. In our view, *bona fide* third-party communications, as described above, can be distinguished from one-way communications designed to control the movement of a remote object. Although an exception was made to the license requirement for two-way communications, we do not believe that it would be in the public interest to further extend this exception by interpretation of the rule to include one-way communications.

6. In its argument that the Bureau ignored the parallelism between the Amateur and the Radio Control Service Rules (which the petitioner insists exists) the petitioner misstates the basis and purpose of the proposed rule making in Docket No. 19572. That proceeding proposed amendment of Part 97 rules insofar as they pertain to the radio control of remote model craft and vehicles. The petitioner states that: "The purpose of the rules change, the Commission indicated, was to establish comparability between the rules governing like-type operations in the Amateur Radio Service and the Citizens Radio Service.'" However, a close reading of that Notice of Proposed Rule Making will reveal that it was the petitioner in that proceeding (also AMA) who "states a desire for comparability between the rules governing like-type operation in the Amateur Radio Service and the Citizens Radio Service." In fact, the objectives of the Commission's proposal allowing amateur radio stations to be used for control of remote models were simplification of station identification, logging, and portable operation; special provisions requiring the amateur transmitter to bear an identifying marker; and, provision for a maximum mean power output of one watt for transmitters qualifying for operation under these special provisions. In this connection, see *Rock Creek etc. Dist.* v. *County of Calaveras*, 29 Cal. 2d. 7, 9, 172 P.2d. 863, where the court said "the objective sought to be achieved by a statute as well as the evil to be prevented is of prime consideration in its interpretation." Nowhere is it suggested in the Commission's Notice of Proposed Rule Making in Docket No. 19572 that *all* of the rules relating to operation of a radio station in the R/C Service for control of a remote object would be carried over into the Amateur Radio Service when an amateur radio station is so used. This is an important point because much of the petitioner's argument arises from the fact that the staff's decision holds that the provisions of § 95.265(b)(6)[3] are not implicitly contained in the Part 97 rules relating to the use of an amateur radio station to control models. We turn to a fundamental rule of statutory construction to support the staff's position. In *People v. Valentine*, 28 Cal. 2d. 121, 142, 169 p.2d. 1, 14, the court held that where a statute, with reference to one subject contains a given provision, the omission of such a provision from a similar statute concerning a related subject is significant to show that a different intention existed.

The transmission or delivery of the following amateur radio-communication is prohibited:

7. Finally, petitioner alleges that the Bureau erred in adopting an interpretation of "third-party" that is inconsistent with other provisions of the Amateur Radio Service Rules and with Commission-accepted Amateur practice. Specifically, petitioner cites §§ 97.89 and 97.91 as conflicting with § 97.79(d), if § 97.79(d) is read to apply to two-way amateur ratio communications. We do not subscribe to petitioner's theory relating to those sections. The *definition* of amateur radio communications is contained in § 97.3(b). There, such communication is defined as noncommercial radio communication by or among amateur radio stations solely with a personal aim and without pecuniary or business interest. In §§ 97.89 and 97.91, the *uses* of an amateur station are set forth. It may be used to communicate with other amateur radio stations (two-way communications) or to control remote objects (one-way communication) (see § 97.89); or, to engage in certain kinds of additional one-way transmissions such as sending information bulletins, or conducting a net operation, as in a "round-robin" discussion (see § 97.91). Petitioner says that § 97.79(d) should have the term "two-way" in its provisions, and that, since it does not, a non-licensed person should be able to engage in *all* the types of communications permitted by §§ 97.89 and 97.91. We do not agree. The provisions of § 97.79(d) clearly contemplate only two-way communications. For example, that section requires a control operator to be present and continuously monitor the radio communications. Monitoring in § 97.79(d) refers to message content. It would be ludicrous to believe that the Commission would require monitoring of a steady hum or tone-signal, which is the type of signal that is used in a typical one-way communication designed to control a remote object.

8. Petitioner further states that, under the Bureau's interpretation, there must be two-way communications established between unlicensed amateur radio operators before a non-licensee may participate. Petitioner further argues that, if followed through, the Bureau's interpretation would prevent, for example, a non-licensee from sending an informational bulletin at a licensed station, addressed in general, to "all amateurs", since there is no contact with another station involved. We could not agree more. That is precisely what § 97.91 does. It requires that only licensed amateur radio operators send such general bulletins over the air. It is interesting to note that, in practice, it is the American Radio Relay League's station W1AW from which the bulk of such bulletins emanate. All of the persons at the League's headquarters who send such bulletins are duly licensed amateur radio operators. Persons sending such bulletins from any other amateur radio station are likewise expected to be licensed operators. Moreover, in the "round-robin" discussions that § 97.91 allows, it is licensed operators, with an interest in such net operations, that the rule contemplates.

9. Petitioner offers a hypothetical case where Licensee A operates a repeater equipped with "autopatch" (a way of connecting an amateur radio station to the telephone landline circuits). The station in repeater operation operates under A's call sign and A is the control operator. Given these facts, petitioner says that if A makes an autopatch call it would be unlawful under the staff's interpretation of § 97.79(d) because communications between amateur stations do not exist. Petitioner further says that another amateur station that uses the repeater to make an autopatch

[1] Section 97.79 Control operator requirements.

(d) The licensee of an amateur radio station may permit any third party to participate in amateur radio communication from his station, provided that a control operator is present and continuously monitors and supervises the radio communication to insure compliance with the rules.

[2] Section 97.114 Third party traffic.

(a) International third party traffic except with countries which have assented thereto.

(b) Third party traffic involving material compensation, either tangible or intangible, direct or indirect, to a third party, a station licensee, a control operator, or any other person.

(c) Except for an emergency communication as defined in this part, third party traffic consisting of business communications on behalf of any party. For the purpose of this section business communication shall mean any transmission or communication the purpose of which is to facilitate the regular business or commercial affairs of any party.

[3] Section 95.265 Operation by, or on behalf of, persons other than the licensee.

* * * * *

(b) Stations may be operated only by the following persons, except as provided in paragraph (c) of this section:

* * * * *

(6) Any person under the control or supervision of the licensee when the station is used solely for the control of remote objects or devices, other than devices used only as a means of attracting attention; and

512-MHz FREQUENCY COUNTER FROM HEATH

The IM-2420 features four gate times and 8-digit resolution for precise readings and includes a period function to give cycle time in seconds and a frequency ratio function to provide the ratio between two input frequencies.

A standby power switch can keep the crystal oven warm for maximum frequency accuracy. The oven is proportionally-controlled to keep the internal timebase within 0.1 parts per million over a wide temperature range, with drift controlled to less than 1 ppm per year. The IM-2420 also has provisions for using external timebase signals.

Four gate times and an 0.43-inch-high, 8-digit LED display provide the resolution necessary to measure UHF signals. The IM-2420's 4-15-mV typical sensitivity allows counting of low-level signals. Trigger level control assures stable counting when noise is present, and provides more accurate measurement of complicated waveforms. Frequency measurements can be made by direct connection or by using the optional SMA-2400-1 swiveling telescopic antenna. The IM-2420 frequency counter can be wired for either 120- or 240-V ac operation. *Heath Company, Dept. 350-660, Benton Harbor MI 49022.* Reader Service number 480.

SQUELCH-TAIL ELIMINATOR

Circuit Electronics, Inc., of Salina, Kansas, is introducing three models of a repeater squelch-tail eliminator called the "tail-chopper." All models use temperature-compensated operational amplifiers and digital logic, feature 6-dB SINAD sensitivity, wide temperature range, LED to indicate squelching, and maintain normal hysteresis to 0.1 microvolt.

The TC-2100 is a universal module that can be connected to most repeaters to eliminate squelch tails. It has a squelch enable-disable function if needed for tone operation, simple hook-up for 12 V and discriminator, and transistor or relay out.

TC-2000 is a plug-in module to the rear of Regency's U10R UHF repeater. Simple one-wire hook-up eliminates squelch temperature problems. The existing squelch can remain functional and it does not affect tone operation.

The TC-2200 is a PC board with instructions and may be mounted inside a receiver in a repeater or mobiles.

For further information, contact *R. L. Hruska, 621 Bishop, Salina KS 67401; (913)-825-9463.* Reader Service number 483.

Ten-Tec touts two tuners.

200-WATT ANTENNA TUNERS

Two new antenna tuners from Ten-Tec feature two-inch, 47-tap toroids with silver-plated 18-gauge wire and tape selectors. Used in a wide-range "T" network with variable capacitors, the toroids permit vernier tuning for easy, accurate adjustment.

The tuners match dipoles, inverted vees, long random wires, windoms, beams, rhombics, mobile whips, Zepp, Hertz, and similar antenna types over a frequency range of 1.8 to 30 MHz.

A front-panel five-position antenna selector switch offers a choice of dummy load, one of three different antennas, or tuner bypass for one of the antennas. Also, one antenna may be a long-wire type.

The tuners will match conventional 50-75-Ohm unbalanced outputs to a variety of unbalanced or balanced load impedances. A built-in balun converts one antenna to a balanced configuration if desired (maximum balanced load on 160 and 80 meters is 500 Ohms). Power ratings are 200 Watts, rf, intermittent, 100 Watts continuous (useful for any transceiver with input power up to 200 Watts).

Model 228 has a built-in swr bridge, forward/reverse switch, sensitivity control, and a meter which indicates swr ratios between 1:1 and 5:1. Size is 3-5/8"H × 10-1/2"W × 7-3/4"D; weight is 3-1/2 lbs. Model 227 is identical but without the swr bridge. Size is 3-5/8"H × 8-1/4" W × 7-3/4" D. *Ten-Tec, Inc., Highway 411 East, Sevierville TN 37862; (615)-453-7172.*

The ZL/DF Special

—your next T-hunt could be a hare-raising experience

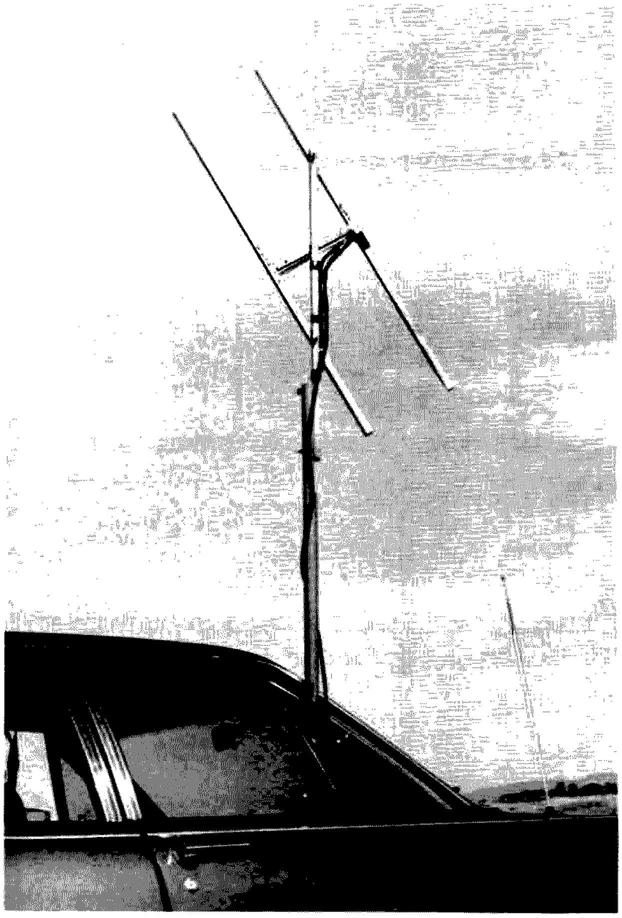
Jane Rice AD6Z
3130 Morningside Drive
Oceanside CA 92054

When our local radio club formed a two-meter T-hunt group, my OM and I decided, after tagging along a few pleasant Sunday afternoons, to put together some sort of simple antenna and join in on the fun of rabbit hunting. We noted that the most successful hunters in the group took up pursuit with four-element quads or yagis. However, we also noted that a four-element quad or yagi has a boom length of about six feet and that the various home-brew devices used to attach this impressive but awkward length to a vehicle looked a bit tricky to construct.

Willing to put out a moderate amount of effort, we agreed that any antenna we built would require no complicated car mounting, that it would be light and small, that it could be flung together cheaply and easily in a few spare hours, and that it would aim us generally in the direction of a hidden transmitter.

Since we had no experience building direction-finding equipment, we didn't realize that our specifications weren't easy to fill until we'd assembled several trial configurations. With most, we used up a lot of gasoline and the rabbits got away.

We tried loops, but had no luck getting a sensor to choose between the two major lobes in the loop's response pattern. Then we tried phased quarter-waves that stubbornly exhibited a radiation pattern reminiscent of a lace doily. Finally,



The completed antenna is mounted through the wind-wing of a car.

Mathematical premises used in this article

A. λ in free space = 984 ÷ MHz (for feet) or 11808 ÷ MHz (inches).
B. $\lambda/2$ in free space = 492 ÷ MHz (for feet) or 5904 ÷ MHz (inches).
C. K-factor of 300-Ohm twinlead at two-meter frequencies = .965.
D. Velocity factor of 300-Ohm twinlead = .82.
E. Length of $\lambda/2$ folded dipole made from 300-Ohm TV lead-in at 146.5 MHz is 5904 × .965 ÷ MHz = 38-7/8".
F. Velocity factor of RG-59/AU coax = .66.
G. Electrical $\lambda/4$ of RG-59/AU at 146.5 MHz is: (11808 ÷ 4 × .66) ÷ 146.5 MHz = 13-1/4".

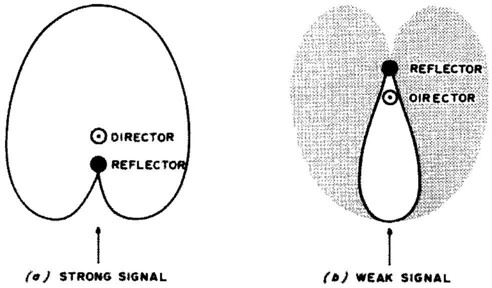


Fig. 1. Response pattern of ZL special. In (a), the director and reflector are positioned so that the null indicates the direction of a fairly strong transmitted signal. In (b), the antenna has been rotated 180 degrees to get a peak bearing on a very weak signal. Gray areas represent that part of the normal response pattern that is lost when receiving weak signals.

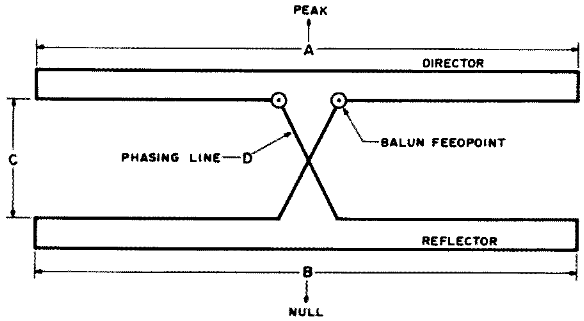

Fig. 2. The ZL Special is composed of two phased driven folded dipoles made from 300-Ohm twinlead. The driven director is 4.4% shorter than a half-wave element and the reflector 1.7% longer. Formulas for dimensions in inches: A = 5446 ÷ MHz; B = 5794 ÷ MHz; C = 1266 ÷ MHz; D = 1266 ÷ MHz. Dimensions for 146.5 MHz are: A = 37-1/8"; B = 39-1/2"; C = 8-5/8"; D = 8-5/8".

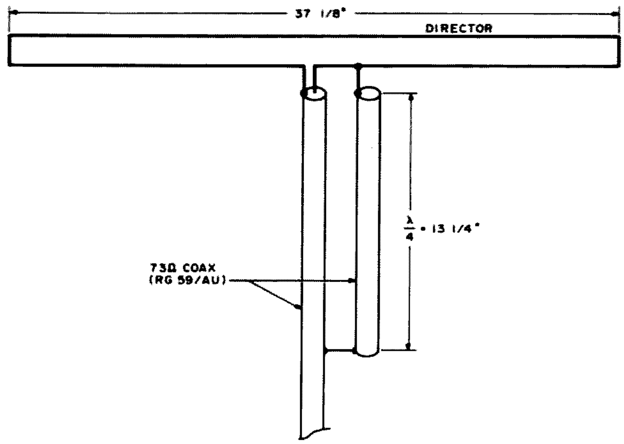

Fig. 3. Dimensions given for the 1-to-1 balun are for 146.5 MHz using coax with a velocity factor of .66. For other frequencies, balun length in inches is calculated from 2952 × .66 ÷ MHz.

when we were on the verge of reconsidering quads and yagis with a less critical eye, one of the more knowledgeable old-timers in the area recounted his successful T-hunting experiences using a two-meter ZL Special and suggested we try one of those.

In an old edition of *The ARRL Antenna Book* and in further reading (see references), we found plans for low-band horizontal ZL Specials. Scaling one down to two meters and upending it to a vertical position seemed to present no problems, so we built it. Happily, it worked, more than fulfilling our original optimistic requirements. The completed antenna shown in the photograph weighs one pound, has a turning radius of thirteen inches, and is easily disassembled.

Car mounting is accomplished by setting a wooden closet pole through the wind-wing and into a five and one-half ounce juice can that is screwed to the car floor. Cost of materials is under ten dollars and construction time under two hours.

As for aiming us in the right direction, we can claim without modesty that we have ferreted out our fair share of hares.

Response Pattern

The modified ZL Special presented here consists of two driven folded dipoles phased to produce a cardioid (heart-shaped) pattern. As seen in Fig. 1(a), this unidirectional pattern exhibits a very sharp null in received signal strength when the driven reflector is exactly between a transmitted signal and the driven director. This null gives a more precise indication of signal direction than the broader peak readings, so following the null makes best use of the antenna while DFing.

An exception occurs when the transmitted signal is extremely weak. In such cases, the sharp null pattern will be lost at the receiver, and it becomes necessary to rotate the antenna 180 degrees to follow peak readings. As the distance between hunter and rabbit narrows, the peak readings become broad and the antenna is again turned to utilize the null. The null will continue to indicate direction even when working extremely close to the hidden signal source.

Directivity and Gain

In addition to its compact size, the ZL Special has another unusual characteristic that makes it ideal for T-hunting: It combines excellent directivity with low gain. Front-to-back ratio is in the neighborhood of 22 dB while forward gain is only about 3 dB.

The low gain is an asset because, contrary to what is often assumed, it is more difficult to locate the source of a strong signal than that of a weak signal. A strong signal, when close enough, will saturate the receiver's front end and pin the signal strength meter regardless of the antenna's bearing, completely wiping out all DF capability.

One disadvantage of using quads or yagis for DFing is that each element that is added to sharpen directivity incidentally increases gain. Signal attenuators, an essential item with any T-hunt antenna, compensate for much of the problem; but given equal situations, a low-gain antenna such as the ZL Special will maintain its directivity closer to a signal source than a high-gain antenna.

Polarization

When first trying out the antenna, we assembled it so that polarization was vertical. Results were fairly good, but proximity to the car body caused some pattern distortion. This problem was greatly reduced by tilting the antenna framework 30 degrees from vertical. As a bonus, the array also seemed less apt to re-

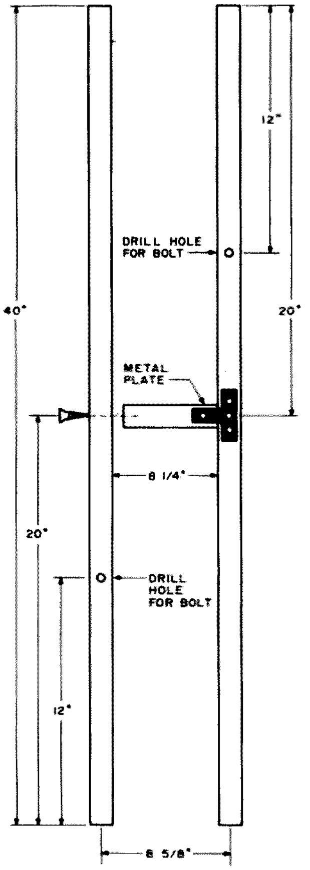

Fig. 4. The ZL Special is tacked to this framework made from ¾-inch-square wood. Dimensions given are for an antenna cut for 146.5 MHz.

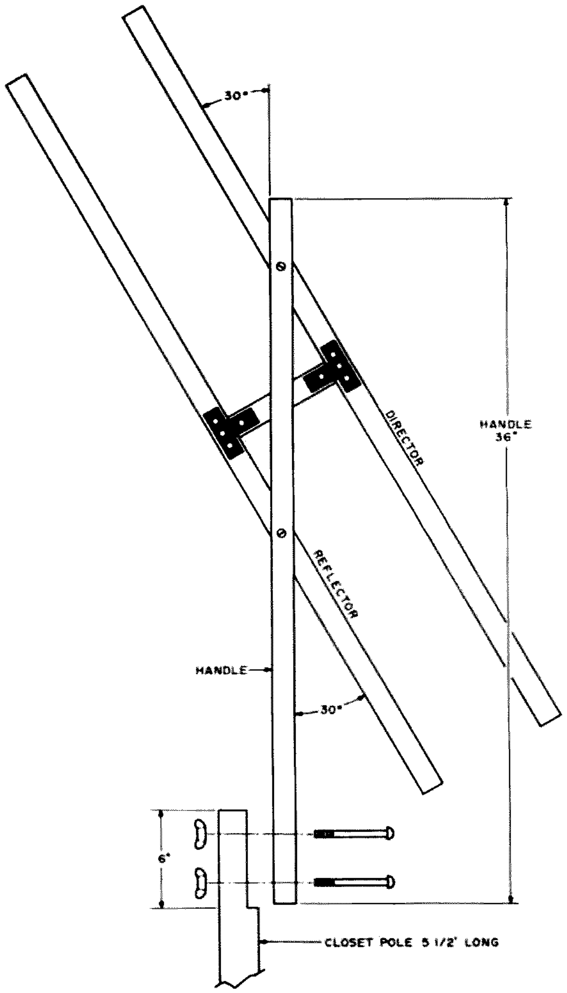

Fig. 5. The positioning of the "H"-shaped framework on its handle determines the tilt of the antenna. The handle is then bolted to a 1¼" wooden closet pole.

spond to signal reflections from nearby signposts, power poles, etc.

Spacing and Phasing

For the best front-to-back ratio, spacing between the two driven elements should be close to .123 wavelengths. Designs should never employ less than .1 wavelengths because pattern distortion and characteristic impedance changes will result.

In our antenna, .112 (one-ninth) wavelengths was used because it happened to be the spacing needed to accommodate the phasing line section. In calculating spacing (as well as element lengths), a K-factor of .965 is assumed for the twinlead at two-meter frequencies. The standard wavelength formula (984 × .965 ÷ MHz), with results divided by nine, is suitable. In Fig. 2, the formula given for spacing, although simplified, is identical except that the one-ninth wavelength will be in inches rather than feet.

The phasing line in the ZL Special acts as part of the transmission line. Its purpose is to provide, as closely as possible, the 135 electrical degree phase difference between director and reflector that is required for the cardioid pattern.

Assuming a velocity factor of .82 for the 300-Ohm twinlead, an electrical halfwave at 146.5 MHz is 492 × .82 ÷ MHz, or 2.75 feet. Then the 180 degrees in the half wavelength divided by 2.75 feet equals 65.36 electrical degrees per foot. Therefore, a piece of 300-Ohm twinlead that is .72 feet long will yield (by .72 × 65.36) 47 electrical degrees. This figure, when combined with a 180-degree twist in the phasing section (shown in Fig. 2), comes close to ideal phasing. Actually, 360° − (180° + 47°) = 133 degrees. The formula for phasing line length given in Fig. 2 was derived in the manner just described and will provide 133 electrical degrees at any chosen two-meter frequency.

The fact that the phase shift is two degrees less than ideal and that the element spacing is .011 wavelengths less than optimum is justified from a constructional standpoint. Note in Fig. 2 that the phasing line and spacing have the same dimension, making construction easy. If the ideal figures were carried to construction, the phasing line would turn out to be shorter than the space between elements, and the elements would have to be bowed in to make ends meet.

Construction

For antenna elements and phasing line, the use of lightweight 300-Ohm twinlead is recommended as it is easier to work with than a heavily insulated type. Formulas for dimensions and their application to 146.5 MHz are given in Fig. 2. Especially note the twist in the phasing section. A quarter-wave 1-to-1 balun, made from the same coax as the transmission line, is added at the director feedpoint to prevent unwanted currents from flowing on the coax transmission line. Details are in Fig. 3. The balun will not affect the impedance at the antenna feedpoint, generally reported to be about 70 Ohms. 73-Ohm coaxial cable (RG-59/AU) will provide a suitable match to both the antenna and a 50-Ohm receiver. When used for transmitting, the antenna exhibits an swr of 1.5 to 1 at design frequency and, compared to a dipole, is relatively broad-banded.

After the antenna is completed and the transmission line and balun soldered in place, the assembly is attached to its wooden support by driving tacks through the center of the twinlead. Electrical tape will suffice to hold the feedline and balun to the wooden handle. Care must be taken to maintain even spacing between the transmission line and balun, and spacers (about ½") may be necessary.

Construction details of the support framework and dimensions for a 146.5-MHz antenna are shown in Figs.4 and 5. The framework is a wooden "H" made from ¾-inch stock. The crossbar on the "H" is first screwed in place and then the joints are reinforced by adding narrow metal T-plates. The handle, of the same stock, is bolted to the framework at points that determine the 30-degree tilt. Make sure that the reflector, not the director, is bolted closest to the bottom of the handle. Finally, the handle is bolted to a 1¼"-diameter wooden closet pole that has one end rabbited to provide a flat surface.

After the juice can has been screwed to the car flooring and the antenna is in place, mark the pole at eye level to indicate the antenna's heading. A marker that can be felt as well as seen is convenient. We used a small rubber screw-in foot, like those found on the bases of radio gear, to indicate the direction of the null.

Since the highest point of the antenna will be about six feet above the roof of the car, keep a sharp eye out for trees with low branches and you will greatly extend the life-span of your ZL Special! Good hunting! ■

A 49-MHz Repeater

—fun project

Any experimenter who has ever pondered the potential of the new license-free 49-MHz band can't help but see freedoms from regulations to experiment here that are denied in ham radio. For instance, a transmitter operating here isn't required to identify by callsigns, nor is it limited to any particular emission. While most hams might not consider this a handicap, an experimenter who requires a radio transmission of short range, as in the case of telemetry, can avoid a lot of inconvenience and cost by using 49 MHz instead of a regular ham band.

I was playing around with several inexpensive 49-MHz transceivers (the two-for-$20 variety) when the idea of a truly license- and restriction-free repeater came to mind. Now, these transceivers run about 20-40 milliwatts of power and have a range of about one-quarter to half a mile, depending on terrain. They have regenerative receivers which don't help the range much, but any VHF ham will agree that 40 mW with a proper antenna and a good receiver will cover distances considerably greater than this. All one has to do is look at the hundreds-of-square-mile ranges of certain repeaters in this country that don't use much more power to see the possibilities.

I didn't expect, or want, distances like this, but being an experimenter at heart, I took up the challenge of 49 MHz to see just what could be possible on this band.

Building the License-Free Repeater

The repeater transmitter was simple. One of the transceivers was sacrificed and altered to stay in transmit-only mode and modified to accept audio from a receiver instead of using its built-in mic. The original frequency of 49.86 MHz was changed by replacing the transmit crystal with one 30 kHz towards the band edge. A quarter-wave antenna was fashioned out of copper wire and the whole assembly enclosed within a six-foot piece of large-diameter PVC pipe. A waterproof connector allows power and audio to be fed to the transmitter through the pipe over a multiconductor cable. Rf chokes and capacitors at this connector bypass and keep down stray rf that could end up down at the receiver. This transmitter/antenna can now be mounted at a reasonable height. The antenna attached to the transmitter is an apparent legal requirement on 49 MHz, but it works to an advantage here.

The receiver used for the repeater was located indoors and connected to a vertical half-wave dipole separated from the transmitter by one hundred feet. It consisted of an old surplus URR-22 receiver with an Ameco CN 50 converter. The repeater transmitter offset from 49.86 caused no desensitizing. That's all there is to it. Notice that since there is no requirement for identification, there is no CW identifier. Also, since there is no requirement against a continuous carrier, the transmitter is left on continuously. The receiver has an added squelch so that the carrier remains quiet except when rebroadcasting a received signal. How simple could it be? No COR, no ID, no time-out timers!

The transceivers all come set to operate on 49.86, so the repeater receiver is tuned to this frequency. Since the transceivers have regenerative receivers, a change of 30 kHz doesn't require much, if any, tweaking to bring them on the new repeater channel.

How Well Does It Work?

With the antennas thirty feet up, communications have been consistent to one-half mile between units and over a mile on numerous occasions. A half-square-mile coverage is about the expected range, which isn't bad when considering that this is supposed to be low-power, license-free radio.

An added bonus to this system is that the continuous repeater carrier quiets the rush noise from the inexpensive regenerative receivers and acts like a squelch. Also, as long as the receiver is quieting, the operator is sure he is within range of the repeater.

I haven't polished the system up any more than described. A better solid-state repeater receiver, more attention to the transmit/receive frequency offset, better transceivers, and so on would no doubt improve the system. It should be obvious that such a repeater could lend itself well to events covering small geographical areas like hamfests, county fairs, or Boy Scout jamborees. No one needs a license to operate, the equipment couldn't cost less, and 49 MHz is free (for now, anyway) of any interference.

If not a repeater, I hope that this article will spark other interesting ideas for using 49 MHz, an experimenter's delight. ■

TR-7400 Behind Bars

—something new in S-meters

One day while evaluating various LED bargraph displays at the workplace, my thoughts momentarily turned to ham radio.

"Hey," I thought. "This bar graph would make a terrific S-meter on my two-meter rig!"

But could it, and the circuitry, be made to fit? I was sure it could, as I have had the meter out of the TR-7400 to replace the lamp bulb. The only questions remaining were: (1) What is the drive level of the existing meter, and (2) could the drive level be used to drive the display without need of an extra amplifier?

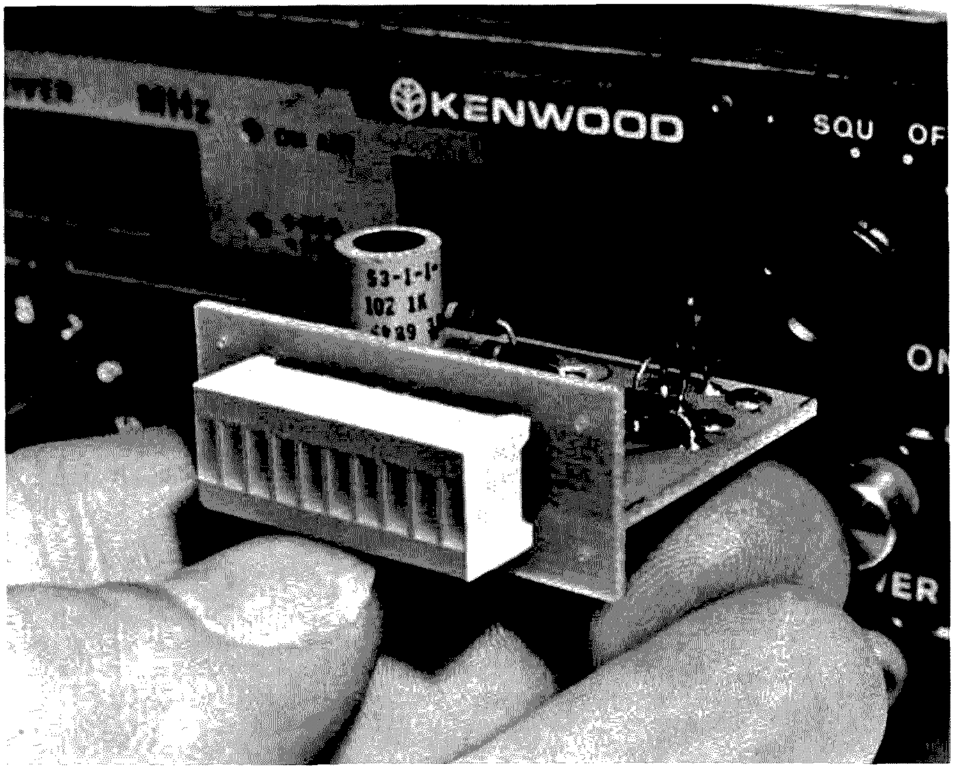

Photo A. Completed unit ready for installation. Note the two-board construction.

Upon arriving home that evening, a little tinkering with the rig was in order to determine the needed circuitry and circuit-board configuration for the conversion. I have always been one of those who has to build everything on a printed circuit board.

I found that the resistance of the meter was around 600 Ohms and that a dc input of 0.3 V was developed across it at a full-scale reading. I also discovered that this voltage increased to nearly 6 volts if the meter was taken out of the circuit. A quick look at the TR-7400 schematic revealed that a simple diode rectifier and capacitor circuit was used to drive the meter.

The circuit appears twice in the Kenwood, as the meter also reads relative output power in the transmit

mode. Each circuit has an adjustment pot inside the rig for trimming the meter. This feature could come in handy later.

Some further experimentation indicated that with a higher resistance load (greater than 600 Ohms), I could get the 1.2 volts needed to drive the bar-graph IC to full scale. I now knew that all the major questions concerning the conversion were answered. I then quickly started design of a PC board. The PC board quickly evolved into a pair of boards.

Sometime in the wee hours, the boards were made, tested, and installed solidly within the TR-7400. The new indicator functioned perfectly and looked as if it had been designed in from the start. The moving bars added quite a touch to the old rig.

The response time of the bar graph is much quicker than that of the old mechanical meter due to the lack of mechanical damping.

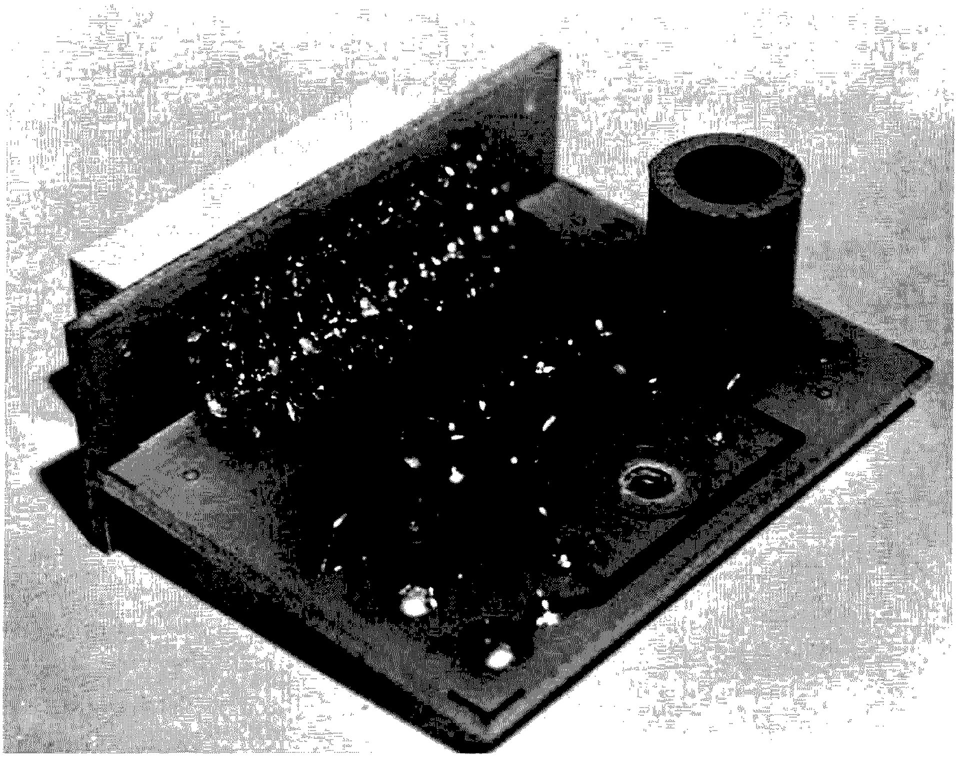

Photo B. The two boards joined using the rows of large pads. The IC is mounted underneath the board.

Circuitry

The heart of the circuit is the National Semiconductor LM3914 dot/bar display driver. This is an amazing IC in an 18-pin DIP. The LM3914 senses an analog voltage and drives ten LEDs, providing a linear graph-type display. All drive for the LEDs is self-contained within the IC, thus eliminating the need for external limiting resistors. LED drive control is provided, however, by selecting only one resistor value. Supply voltage may range from 3 to 15 volts without affecting display brightness. Some caution must be exercised at higher voltages, however, as dissipation in the IC may exceed the safe level. I used the regulated 5-volt source within the Kenwood to drive the display.

The schematic (Fig. 1) shows the circuit to be straightforward. The variable resistor and R1 allow some scaling of the input voltage for calibration. The values may be changed to suit other installations. Remember that 1.2 volts is needed at pin 5 of the LM3914 to drive it full scale. Resistor R3 deter-

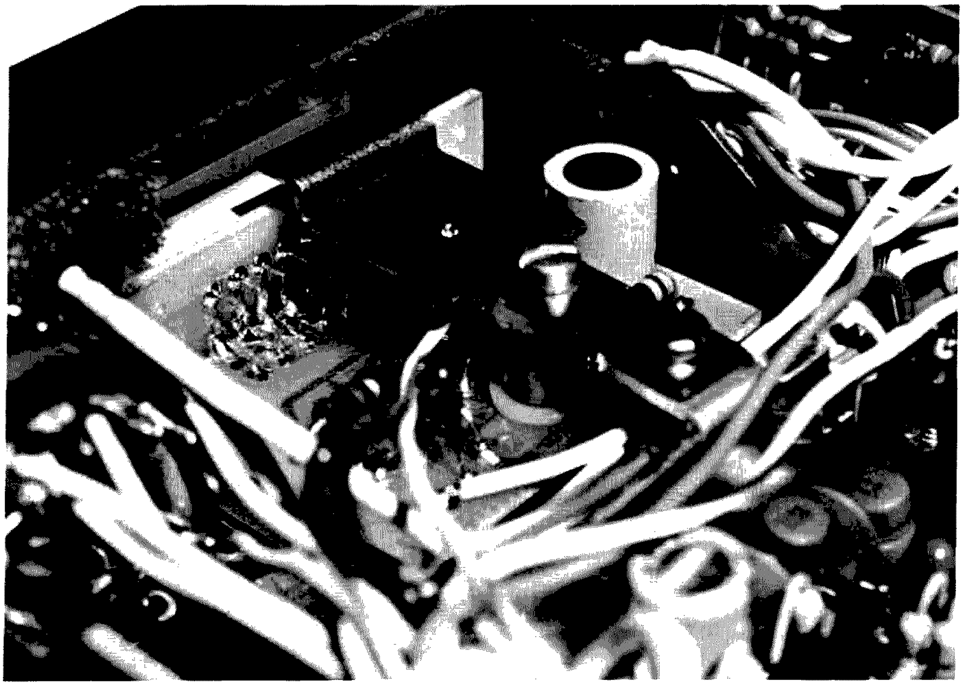

Photo C. Completed circuit installed within the 7400. About 4/10" is needed between the board and bracket.

mines the display brightness; ten times the current flowing in R3 will flow through an LED. The voltage at pins 6 and 7 is equal to 1.2 volts. LED current is 1.2 V/1k = 1.2 mA × 10 or 12 mA. R3 may be made larger if less current is desired. The jumper from pin 9 of the LM3914 to ground puts the display into the bar-graph mode.

Construction

As the circuit is uncomplicated, layout is not critical. I used the pair of small circuit boards shown in Photo A. The boards make a nice clean installation and ease the job of centering the display. In my unit, I mounted the IC on the nonfoil side of the board.

The resistors and trimmer are mounted on the foil side. This makes adjustments readily accessible. Also, the Kenwood has very little room beneath the meter opening.

Photo B shows how the two boards are mated and soldered in place using the flat foil pads on the boards. Be sure the boards are perpendicular and straight when soldering in place. An alternative mounting would be to use ribbon cable as an interconnect between the two boards. This would allow some freedom as to the location of the larger board.

Installation in the TR-7400

Before mounting the display into the rig, you should verify how far the old meter deflects for some reference input signal. Something that causes almost a full-scale reading is best. This will be used to adjust the new meter to compare with the old one. Remove the old meter, bracket, and connections to the meter. The hole in the center of the new meter will be used for mounting. A 4/10''-long spacer is needed between the board and the mounting bracket. One with a threaded #4 hole is ideal. The old meter bracket will need a hole drilled in it so the PC board can be attached using the spacer and screw. Take care in measuring the location of the mounting hole. You want the bar-graph readout to come right up to the front glass in the rig.

Adjustment

After satisfying yourself that the unit is mounted and aligned correctly, connect the black wires from the old meter to the minus pad on the circuit board. Connect the wire that was on the high side of the meter to the signal input on the board. A new wire must be run for the +5-volts connection. Connect a wire from the PC + input to the pin located on the left side of the rig behind the volume control marked "5 V". This is the internal regulated 5 volts. Trim off the old lamp wire so that it does not short out. Recheck all your work.

Turn on the rig and adjust the trimmer with your reference signal being received to obtain the same reading as you had on the old meter. Replace the cover, and that's it. Just one thought on the display. It is possible to insert ten small LEDs in place of the more expensive bar display. The appearance won't be as nice, but it's great for those on a budget.

Note: A kit of all components will be furnished for $13.75 ppd. The kit includes: MV 57164 display, LM3914, trimmer, resistors and capacitors, set of printed boards (drilled), and spacer. A set of boards can be ordered for $3.75 ppd.

Order from: MTEC WB3ATP, Box 17133, Pittsburgh PA 15235. (Pennsylvania residents add 6% sales tax.)■

The Last PL Generator

—this synthesized unit is the last one you'll ever need

Michael J. Di Julio WB2BWJ
97 Woodside Road
Maplewood NJ 07040

Many repeaters utilize a PL™ (private line) system to permit only limited access. If a person belongs to many repeaters, the cost of frequency-determining elements for a conventional PL tone gen-

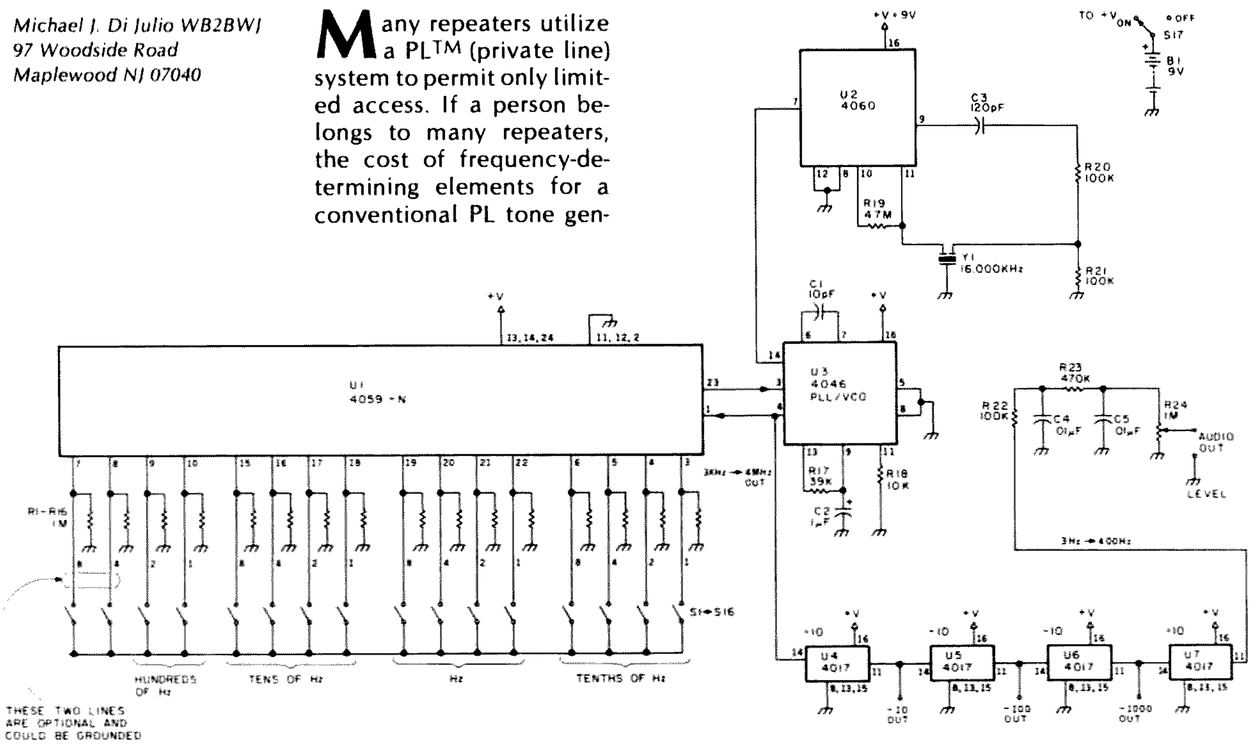

Fig. 1. Synthesized tone generator schematic.

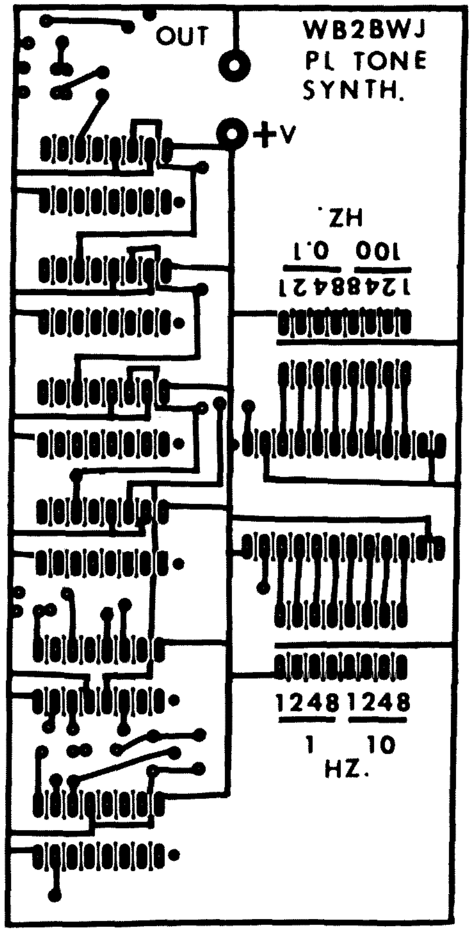

Fig. 2. PC board layout.

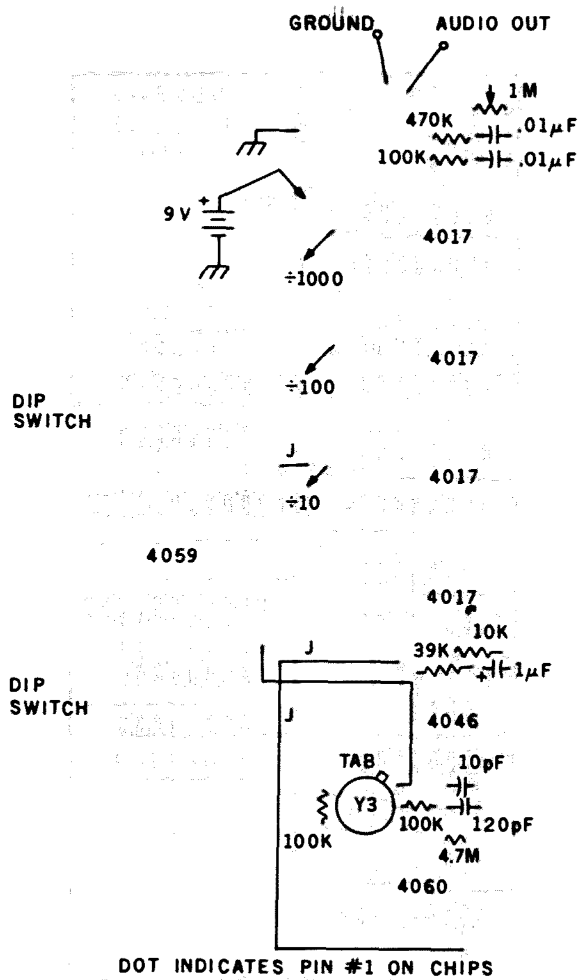

Fig. 3. Parts location.

erator can quickly get out of hand. Additionally, some clubs change their access tone periodically, and it would be convenient to have a synthesized tone generator that could be programmed using thumbwheel or DIP switches.

My design reflects the need for an inexpensive device that is easily programmed and that can generate stable tones in the frequency range of about 60 to 200 Hz. Table 1 is a listing of the common PL tone frequencies and their designators. As it happened, when I had finished my design I had a more versatile instrument that generated signals from about 4 MHz down to 0.3 Hz.

Refer to the schematic in Fig. 1. The device works as follows: The 4046 has an internal vco working in the range of about 600 kHz to 2 MHz. The 4060 is used as the reference source, starting with a 16-kHz crystal and dividing by 16 to generate a 1000-Hz reference which is fed to one input of the phase comparator of the 4046. The vco output of the 4046 goes to the input of the 4059 divide-by-n, and the output of the divider goes to the other input of the phase comparator. A phase-locked loop is thus formed, and the vco output is equal to (n)×1000 Hz, where n is the number programmed into the 4059. As the 4059 is set up, any number from 3 to 9999 can be set on the four thumbwheels or DIP switches. Therefore, the vco could potentially vary from 3000 Hz to 9.999 MHz. At 9 volts, most 4046 chips can work up to about 4 MHz. At higher voltages, frequencies up to about 6 MHz can be realized. If the device is to be used solely as a PL tone generator, S1 and S2 could be eliminated and pins 7 and 8 of the 4059 grounded, as the divide-by-n number will never go over 2000. I have included S1 and S2 in the event that

Designation	Frequency (Hz)	Designation	Frequency (Hz)
L1 or XZ	67.0	2B	118.8
WZ	69.3	3Z	123.0
LZ or XA	71.9	3A	127.3
WA	74.4	3B	131.8
L3 or XB	77.0	4Z	136.5
WB	79.7	4A	141.3
L4	82.5	4B	146.2
YA	85.4	5Z	151.4
L4A or YB	88.5	5A	156.7
ZZ	91.5	5B	162.2
L5 or ZB	94.8	6Z	167.9
1Z	100.0	6A	173.8
1A	103.5	6B	179.9
1B	107.2	7Z	186.2
2Z	110.9	7A	192.8
2A	114.8	M1	203.8

Table 1. Subaudible tones and designations.

the user wishes to go higher than 2.999 MHz in frequency.

The output of the vco is then divided by 10,000, using four 4017 divide-by-10 chips. The pulse output is then fed through a low-pass filter consisting of R22, R23, C4, and C5; the audio level to the radio's microphone input is adjusted with R24. It is important to note that the output of the low-pass filter is not constant with frequency, and so the adjustment of R24 may have to be changed if a radical change in frequency is made in order to maintain a certain deviation. Pads have been provided on the PC board so that the vco output divided by 10, 100, and 1000 is available.

If the device is configured as a pulse generator, a switch could be provided to make these outputs available. For example, with the switches set to 1000, 1 MHz, 100 kHz, 10 kHz, 1000 Hz, and 100.0 Hz are all available with four decades of precision.

The construction of the generator is straightforward and involves only a few discrete components. Figs. 2 and 3 provide PC board layout and parts location. Provision is made on the board for the two 16-pin DIP switches. Numbers have been etched on the board beneath the switches to indicate which BCD digit a particular switch selects. A 1-megohm resistor is required from each of the 4059 program inputs to ground (R1-R16). These resistors can be soldered underneath the board from the switch contacts to the ground buses provided. If the thumbwheel switches are used, eliminate the DIP switches and simply connect the appropriate wires to the holes where the DIP switches would reside.

In conclusion, this project represents an inexpensive state-of-the-art design of a very useful device. In addition to the previously mentioned uses as a PL tone generator and a pulse generator, it can be used as a programmable reference or as the tone generator for a multi-tone FSK modem. ■

Parts List

R1-R16	1 megohm
R17	39k
R18	10k
R19	4.7 megohm
R20-R22	100k
R23	470k
R24	1-megohm subminiature PC-mount potentiometer
Note: R1-R23 are 1/4-W or 1/8-W resistors, 10% tolerance	
C1	10-pF ceramic disc
C2	1-uF tantalum
C3	120-pF ceramic disc
C4,5	0.01-uF ceramic disc
U1	4059
U2	4060
U3	4046
U4-U7	4017
Y1	Statek 16.000-kHz crystal, type SX-1V (available from author for $6.00 postpaid).
S1-S16	Two 16-pin DIP switches or 16 toggle switches or four BCD thumbwheel switches
S17	SPST switch
B1	9-V transistor radio battery

PC boards are available from the author, tinned and drilled on G-10 epoxy, for $15.00 postpaid.

An End to Repeater Time-Outs

—with the IC-211

Anthony R. C. Green
VP2EZ, A4XCR, VS6EZ, G4HRD
Flat 21A,
Fai Hon Building
15, Ngan Mok Street
Causeway Bay,
Hong Kong

When the Hong Kong Amateur Radio Transmitting Society installed our first professional 2-meter repeater recently, the transmission timer was set to two minutes. I decided that I didn't want the ignominy of timing out the repeater, so, after a little thought, I evolved a circuit which fits snugly inside the IC-211 microphone and gives me a 10-to-15-second warning before time-out occurs.

Very little modification needs to be done in the IC-211. All that is required is a 12-volt source attached to pin 3 of the microphone socket. This is obtained from J5 of the power unit.

Some modifications are necessary in the microphone plug. There are three wires and a screen braid. The screen must now be wired to provide the only ground wire for the microphone. The now spare wire is used to carry the 12-volt supply to the time-out unit.

The values of R2 and C1 may need slight adjustment to compensate for variations in voltage and capacitance. It should only be necessary to select R2 to give a time-out alert 10-15 seconds before the repeater switches off.

The green LED is mounted on the top of the hand microphone and it is very noticeable when it starts to flash its warning. ■

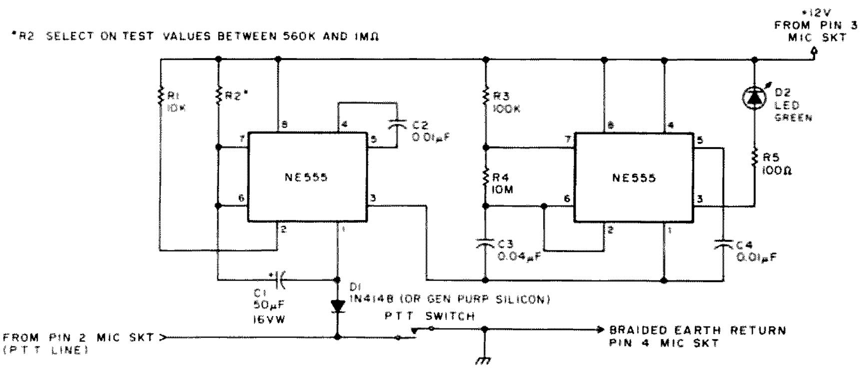

Fig. 1. Time-out circuit flashes LED after one minute, forty-five seconds.

The History of Ham Radio
—part XII

Reprinted from QCC News, a publication of the Chicago Area Chapter of the QCWA.

The assignment to radio amateurs of the short waves below 100 meters brought about a general awakening to the value of this spectrum. In 1924, the broadcasting industry exerted great effort toward the adaptation of short wavelengths to give their programs added coverage to distant listeners by interconnecting stations across the country.

Secretary of Commerce, Herbert Hoover.

The Hoover Conference

The Hoover conference was scheduled to meet in the fall of 1924. Invitations were directed to all radio groups interested in the hearings, in which existing technical radio problems were to be explored. The assembly was to make recommendations to the Department of Commerce for important revisions of then-existing wavelength assignments, allocations, limitation of power, division of time, and such problems which relate to general reduction of station interference. Of major importance, however, was the subject of shortwave usage by broadcasters and commercial stations. The amateurs, supported by the Department, with their constant experimenting with the higher frequencies, had been providing the industry with interest in these higher-frequency ranges, demonstrating their effective capabilities. The radio law of 1912 had given the amateurs, through assignment, the use of all waves below 200 meters.

The Hoover conference was called on to revise and to somehow "make amends" to a region in the spectrum which proved to be not only large but of great future value.

The conference sessions continued from October 6 to 10, 1924. Although radio broadcasting held the center of the stage as far as the broadcasters and listeners were concerned, the radio amateur had by all odds top interest in the outcome of the deliberations. The situation, with about 600 broadcasting stations on the air, with foreign stations all over the world striving to be heard, with a wavelength revolution having set in, and with practically no worldwide rules and regulations to give direction, loomed chaotic in the radio broadcast world.

All the higher frequencies below 200 meters, formerly regarded as unsuitable for commercial purposes, were now eagerly sought as of major importance for DX transmissions. The Hoover conference was set to scrutinize these shortwave regions.

The use of spark transmission, although not ruled out completely by existing laws, nevertheless received its doomsday with the announcement at the conference that all spark should be discontinued by amateurs as well as the commercials. Spark discharges of whatever type and kind caused much of the interference encountered and should be avoided.

The conference gave the broadcasters five wavebands in the short-wavelength region for use primarily for relay broadcasting. All actions taken at the conference were recommendations to the Department, pending further outcome from future legislation.

1924 Hoover Conference Frequency Allocation

Meters	Kilocycles	Allocation
200—545	550—1,500	Broadcast
150—200	1,500—2,000	Amateur (160 meters)
137—150	2,000—2,200	Point to point
120—137	2,200—2,500	Aircraft
109.2—120	2,500—2,750	Mobile
103.3—109.2	2,750—2,900	Relay broadcasting
85.6—103.3	2,900—3,500	Public service
75—85.6	3,500—4,000	Amateur (80 meters)/Army mobile
66.7—75	4,000—4,500	Public service/mobile
60—66.7	4,500—5,000	Relay broadcasting
54.5—60	5,000—5,500	Public service
51.7—54.5	5,500—5,800	Relay broadcasting
42.8—51.7	5,800—7,000	Public service
37.5—42.8	7,000—8,000	Amateur (40 meters)/Army mobile
33.3—37.5	8,000—9,000	Public service/Mobile
30—33.3	9,000—10,000	Relay broadcasting
27.8—30	10,000—10,800	Public service
25.8—27.8	10,800—11,600	Relay broadcasting
21.2—25.8	11,600—14,000	Public service
18.7—21.2	14,000—16,000	Amateur (20 meters)
16.7—18.7	16,000—18,000	Public service/Mobile
5.3—16.7	18,000—56,000	Beam transmission
4.7—5.3	56,000—64,000	Amateur (5 meters)
0—4.7	64,000—	Beam transmission

The conference concluded by listing wavelengths in effect for one year. All wavelengths from zero (0) to 3158 meters were allocated. The radio amateurs retained the previously-assigned wavebands as confirmed, with minor changes, as shown in the box.

The government departments were authorized to work in the wavebands below 150 meters "with due regard to the authorized use given to other legitimate services."

To be noted was the method of allocating wavebands. Namely, the dovetailing of assigned ranges in such a manner that the frequencies in one band were octaves of those in the preceeding band. This manner of band distribution for all services receiving assignments would, therefore, cause disturbances only to the respective assignees operating from one band to the other. Note the distribution, for instance, for the radio amateurs, all being in harmonic relation:

1.5 MHz to 2.0 MHz
3.5 MHz to 4.0 MHz
7.0 MHz to 8.0 MHz
14.0 MHz to 16.0 MHz
56.0 MHz to 64.0 MHz

Theory of Frequency Propagation: Still a Mystery?

There existed an unanswered question in the minds of most. Why are 100-meter waves able to carry across oceans at night with little power? This problem baffled the scientists and radio experimenters in the field. Dr. A. E. Kennelly of Harvard University suggested that there must be conducting layers in the upper regions making possible the transmission of radio waves. The layers most likely represented ionizing action to accomplish such results at long distances. As Professor Kennelly theorized, the greater volume activity of the higher-frequency waves enabled them to cut a sharper conducting boundary surface in the upper air than was possible for the longer waves of the lower frequency. The longer waves had a greater tendency to follow the surface of the earth, thus restricting their efficiency.

The Hoover/White Bills

The changing conditions surrounding radio, especially in the field of broadcasting, definitely necessitated comprehensive legislation by Congress. Hoover had in mind a bill in the form of emergency legislation. He thought of the White Bills which had been pending as holdovers from the previous Congress. In communication with Congressman White, his proposal was submitted in the following form to satisfy the public interest until final legislative policy could be inacted in Congress:

"Be it enacted by the Senate and House of Representatives of the United States of America in Congress assembled, that it is hereby declared and re-affirmed that the ether within the limits of the United States, its territories and possessions, is the inalienable possession of the people thereof, and that the authority to regulate its use in interstate and/or foreign commerce is conferred upon the Congress of the United States by the Federal Constitution."

"That Section 1 of the act of Congress approved August 13, 1912, entitled, An Act to Regulate Radio Communication, is hereby amended by adding at the end of said section the following: The wavelength of every radio transmitting station for which a license is now required by law, its power, emitted wave, the character of its apparatus, and the time of transmission, shall be fixed by the Secretary of Commerce as in his judgment and discretion he shall deem expedient, and may be changed or modified from time to time in his discretion."

The pending White Bill was temporarily sidetracked. The National Association of Broadcasters could hardly disagree with Mr. Hoover's suggestion, so long as he was Secretary, and so long as unfair decisions could be appealed with the consent of the present Secretary.

The amateurs responded by stating that, although the bill needed amending by limiting the life term or by placing discretionary powers into the hands of some appointed radio commission to provide appeals from unfair decisions, no further suggestions would be forthcoming.

A Memorable ARRL Undertaking

The evidence of the popularity and the splendid results obtained with shortwaves in the hands of amateurs was clearly exemplified through the experiences conducted jointly with the United States Navy and the ARRL in the summer of 1925.

A shortwave station, call letters NRRL, was placed aboard the USS Seattle, flagship of the Navy fleet operating in the Pacific waters. ARRL traffic manager F. H. Schnell assembled the transmitter and receiver along customary amateur radio lines, typically breadboard but compact. Schnell was put in complete charge of the floating station, which was stashed in a small cubbyhole on the compass shack of the ship. There was no other vacant space on board. Schnell strung a single #12 wire vertical antenna up in the rigging of the ship. The Hartley circuit used operated in the 20, 40, and 80 meter bands. For a period of six months, Schnell, as sole operator, made almost daily contacts everywhere. He convinced the Navy personnel that long-range transmissions with low power could consistently outperform on short wavelengths, and had definite value over any of the long wave installations aboard ship.■

Half a Loaf

— charger for 6-volt batteries

Gates 6-volt, sealed rechargeable batteries are available through hardware stores and other suppliers. One of these batteries has a 5 Ampere-hour (Ah) capacity. These can furnish standby power for small transceivers and could be used on Field Days or for other remote applications. The sealed batteries do not have the explosive gas problems associated with ordinary lead-acid car batteries and, hence, can be used safely indoors. I use two 6-volt, 5-Ah batteries in series to power a small transceiver.

Consider the battery charger circuit shown in Fig. 1. Two outputs are provided to charge two 6-volt, 5-Ah batteries at a time. One of these outputs can be left disconnected if only one battery needs to be charged. The two 12-volt transformers step down the line voltage to the proper battery charging voltage. Note the alternate primary connection for 220-volt operation. Diodes D1 and D2 change the ac to dc for battery charging. Resistors R1 and R2 limit current for proper fast-charging. Lamp L1 serves a dual function: It limits the current when trickle-charging and provides a visual indication that trickle-charging is occurring. The timer terminals short out the lamp for fast-charging.

Parts layout is not critical, except that R1 and R2 should have adequate room to dissipate their heat when fast-charging is used.

The batteries may be left on trickle-charge indefinitely. The timer setting should be reduced to about 4 hours when charging only one battery. Note that when the timer is timed out, the batteries are automatically placed on trickle-charge. A single battery also can be left on trickle-charge indefinitely. ■

The Great Aluminum Cover-Up

—how to paint the stuff

Editors' Note. Various potentially dangerous chemicals are used in cleaning and preparing aluminum for painting. Along with the author's suggestions, remember to provide proper ventilation of your work area and that many chemicals can damage skin and eyes. Also, acetone and lacquer thinner are highly flammable. 1-1-1 trichloroethylene may be more difficult to obtain in hobbyist quantities but is one of the non-flammable "safety solvents." Above all, if you are not sure of a chemical's risks, assume the worst. Either find out how to use them safely or don't use them!

Let's face it, aluminum is hard to paint. Sometimes we'd rather switch than fight.

Wood cabinets are great if you want the antique look, but it doesn't fit in well with the rest of your modern gear—and the shielding properties are not the best. Steel takes paint easily, but the material is hard to work with. Drilling is okay, but the stuff sure dulls a nibbling tool fast. Also, bending a fair-sized piece is more than my small brake can hack. Sheet steel is not the most readily available material for the home hobbyist, anyway. Aluminum is the ideal material to work with, if only it could be finished easier.

There is, of course, the trend toward plastic covering materials. Although dry transfers will adhere reasonably well to plastics, decals can be a problem. Also, the available textures and colors may not suit your needs.

There is the old standby of etching in a lye bath, but I get tired of all the satin aluminum panels staring me in the face, and sometimes gray stains which are not removable appear during the process. A good etch involves many of the same steps I'm going to cover below, so why not paint? The fact is, it *is* possible to paint aluminum reliably.

I began to understand the secrets of painting aluminum when I started construction of a home-built airplane. Aircraft people worship aluminum for its structural properties, so they had to learn to put on finishes that would not come right off. The primary secret of this process is that *cleanliness is next to godliness*! You will not get paint to stick to aluminum if any grease or oil is left on the surface.

There are two types of cleaning agents useful for cleaning aluminum. One is a solvent cleaner, such as acetone or trichloroethylene. The other is a detergent cleaner. Although the latter is generally a more powerful degreasing agent, it does react with aluminum and it has other problems. The more powerful detergents are quite caustic and combine chemically with aluminum. This is not always bad, but you may not want that action. Also, whereas solvents will evaporate completely from a surface, the detergent may leave a soapy residue. (You may clean off this residue with a solvent.)

As a general rule, keep the aluminum panel or piece reasonably clean as you work with it. Of course, fingerprints are inevitable, but don't plop the piece in a grease smudge when you set it down, and *never* leave a piece of aluminum sitting on a concrete floor because concrete and aluminum react strongly.

When all the drilling, cutting, and filing are done, you are ready for finishing. Clean the part in a mild detergent. Rinse thoroughly with plenty of water. Wait—don't pick up that piece! Even if you think your hands are clean, oil will appear on your skin very rapidly. From this point until the piece is primed, it must not be handled with bare fingers. Although paper towels can be used if you are careful, I recommend wearing plastic or rubber gloves.

The next step is called chemical conversion. The idea is to replace the surface layer of aluminum with some chemical to which the pain will adhere better. Although there are special mixtures sold for this purpose, they are not usually easy to come by. The easiest and cheapest way I have found is to use a product called Aluminum Jelly (although Naval Jelly also will work). This stuff is found in most hardware stores.

Brush the goop on, let it sit for a few minutes, and then rinse it off, using lots of water. You won't notice any change of appearance at this point. Next is a two-step cleaning process. Again use the mild detergent, followed again by a thorough rinse. Now, clean it with a solvent cleaner, such as lacquer thinner or trichloroethylene. Unfortunately, this immediately raises a problem. These solvents will probably dissolve your gloves! For this step you must use your bare hands, handling the aluminum part with a paper towel. Now we are ready to paint.

Aluminum must be primed with a zinc chromate primer. Don't settle for anything else. There are two kinds of zinc chromate primer. One is yellow, the other is green. The green stuff is recommended for aluminum, but unfortunately it is hard to get. The yellow kind is found in most hardware and paint stores, and will work, although it should be your second choice. Try to find the green primer at aircraft supply

stores. It is available in spray cans.

Applying the primer calls for a good spraying technique. The primer dries pretty fast, so you can give the piece a quick, light coat, wait one or two minutes, and then give it a heavy coat. This helps to prevent runs. If after the piece dries you have any runs, "orange peel," or dust in the finish, sand carefully with number 600 sandpaper. If you have to sand, remember to wear gloves, and do a follow-up by cleaning with isopropyl alcohol. This solvent will remove a reasonable amount of crud, while not dissolving the primer.

Now you are ready for painting. If spraying, I recommend that you buy the type sold for painting plastic model airplanes. There is a tremendous selection of colors available, both matte and glossy. More important, however, is the spray head. These spray cans have heads with tiny holes which give an extremely fine spray, producing a very smooth finish. After spraying, allow at least twenty-four hours for drying, especially if you are dealing with more than one color.

Next, letter the panels with dry transfers or decals. Whichever you use, they should be protected by a clear finish. So, again from the model paint counter, use either a clear matte or clear gloss spray. Be careful when spraying a clear finish, because it is very easy to put it on too thick. Use very thin coats, especially on the matte. The matte will dry in a few hours. The gloss should be put on until it first begins to look shiny, and then it should not be handled for twenty-four hours.

There, that wasn't hard, was it? It was? Yes, but aren't the results worth it? ■

Home-Brew X-Band Wavemeter

—indispensable test gear for microwave mavens

The need to know the operating frequency of an amateur signal in the X-band assignment can be met with an adjustable cavity wavemeter and a detector. The cavity can be adjusted so that it accepts a small amount of power from the transmitter, and the detector, which is coupled loosely to the cavity, "sees" this energy and converts it to a small current that will operate a microammeter, which serves as a resonance indicator.

The wavemeter must have some sort of dial which can be calibrated in frequency. The accuracy of this calibration will depend upon many factors, such as the temperature stability of the cavity, the resettability of the adjusting system, and the exactness of the calibration reference. There are others, but these are the three which will concern us while constructing a suitable unit. The other problems will become evident as we move along.

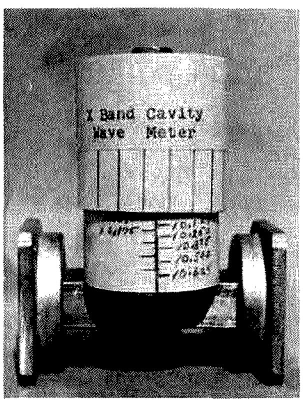

Photo A. Cavity wavemeter for X-band.

A cavity wavemeter is a parallel resonant circuit (see Fig. 1). You have used these devices as traps in the output of your transmitters on the lower frequencies and in many other circuits of your equipment. The operation of a microwave unit isn't different from those. The Q of the circuit in which it is used and the Q of the wavemeter itself make the difference for a calibrated frequency reference. A microwave cavity such as the device we are about to construct can have a working Q of nearly 3000. The working Q will depend upon the loading of the cavity and several other factors.

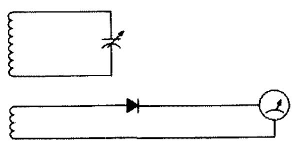

Fig. 1. Parallel resonant equivalent circuit of wavemeter.

An important limitation to recognize is that the device we are making will put you within the band limits, but it is not an absolute frequency meter.

A cavity wavemeter circuit diagram might look like the circuit shown in Fig. 2. A difference in the circuit when using waveguide for the transmission line will be, for example, that the coupling loop in Fig. 1 is a one-turn link to the tank coil. In the microwave configuration we will use, this is simply a small hole in the E-plane wall of the waveguide. The diameter of the hole determines how much coupling there is to the tank circuit, which, in our case, is the cavity. The diameter of the hole controls coupling and many other factors. It must be placed carefully so that the match to the transmission line will not be upset.

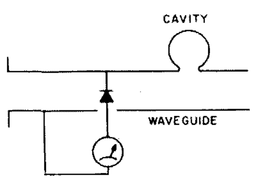

Fig. 2. Cavity wavemeter circuit diagram.

Now, let us examine the construction of a cavity wavemeter for X-band. (See Fig. 3.) The cavity we will construct is, in microwave parlance, a right circular cylinder cavity operating in the TE_{011} mode. It is mounted on the E-plane of an X-band waveguide, off center so that the center of the cavity will sit directly centered over a hole in the waveguide. This hole is called an iris hole. The remainder of the cavity bottom, which hangs over the waveguide, is covered with a brass half-circle soldered in place. This is shown in

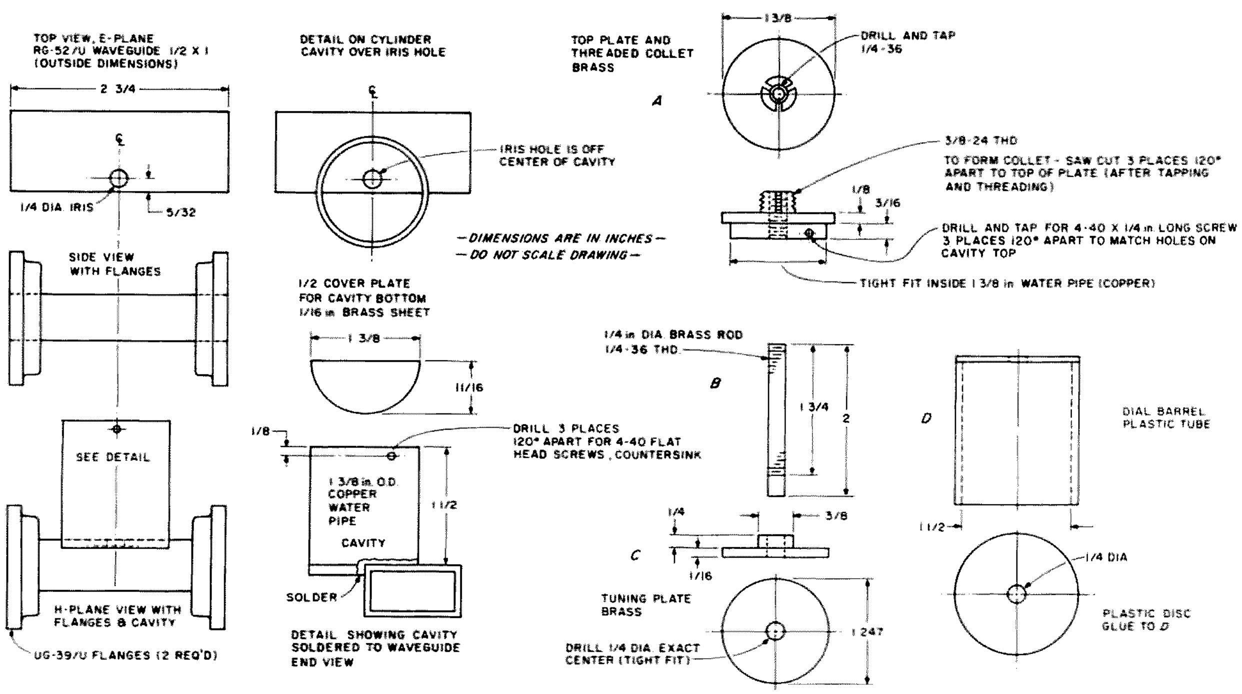

Fig. 3. Construction details for cavity wavemeter.

the photos and drawings accompanying this article.

Tuning of the cavity is accomplished by varying its length. This is done by moving a circular plate longitudinally within the cavity cylinder. A lead screw fastened to the circular plate serves as the device to move it into the cavity. The lead screw must have very fine threads, and the bushing which guides it also must have threads that fit well. A set of three cuts equally spaced around the diameter of the bushing will serve as a collet-threaded bushing when fitted with a small compression nut and lock. This particular part of the construction should be given great care since it directly affects the resettability of the wavemeter. In a commercial unit, a micrometer barrel often is used to control the circular plate motion, giving a high order of accuracy.

In the design shown, a barrel similar to a micrometer was used. It is larger, however, allowing the calibration to be inscribed more easily—and for me to read without my glasses.

The disk is constructed from a piece of flat brass at least 1/16" thick. Dimensions of the disk shown in the drawings should be followed carefully. As you will note, the dimensions allow only .03-inch spacing between the wall and the disk edge. This means that the drive mechanism must also be placed in the center of the drive holder. In each case, it is best to have your friendly machinist fabricate these pieces on a lathe. This means that the top cover, the disk, and disk holder all must be centered exactly or the disk will rub on the cavity walls.

The disk must have some absorbing material added to the back of it. This is necessary because the back of the cavity—that is behind the disk—otherwise can support resonances which wll be coupled weakly from the waveguide and will produce unwanted responses which can mislead the user. The absorbers may be constructed from a disk made of a piece of attenuator card. If you have access to powdered iron material, paper can be shaped around the periphery of the disk to make a form. Mix the powdered iron particles with some coil dope and pour in enough to make a level surface about 1/16" thick. Be sure that the surface is held level while the mix is hardening. (Powdered iron can be obtained from cup core manufacturers or, if you are really ambitious, you can make your own simply by crushing a cup core with a steel roller. Make sure that the particles are very small.) After the mix has hardened, be sure to remove all of the paper and glue from the edge of the disk.

Next, construct the waveguide section by mounting the two flanges, one on either end of the guide. This is done by cutting the waveguide ends square and then removing all burrs from them with a smooth file. Each end will have a flange soldered in place. This is done simply by sliding the flanges on each end of the guide, after first applying a small amount of soldering paste (flux) to each end. Now heat the entire assembly until the flux runs and turns the copper waveguide a deeper color. Apply just enough solder so that it will run around the joint. When this operation is completed, lap the ends of the flanges against a piece of very fine emery paper. Now inspect the joint to be sure that there are no gaps in the solder around the face of the joint.

Next, measure the distance between the rear butts of the flange, and in the center of this distance, using a square, draw a line across the E-plane of the waveguide.

On one side of the guide lying on this line, place a centerpunch mark at the distance from the outside wall shown in the mechanical assembly drawing, Fig. 3. Now drill the hole also described in this detail. Deburr this hole inside and out of the guide so that it is smooth. This is the iris

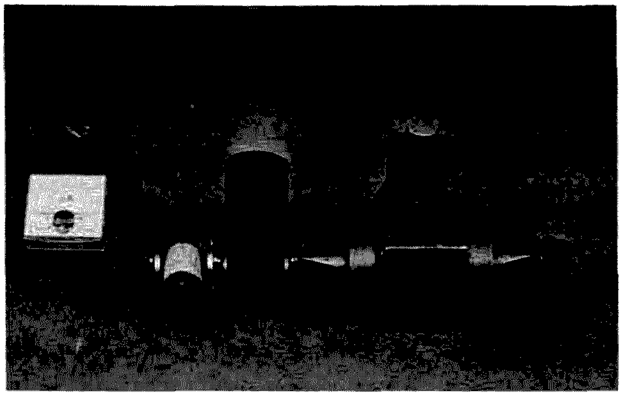

Fig. 4. Test setup for calibration, as described in the text.

coupling hole, and it should be perfectly round with no burrs or raised pieces sticking down into the waveguide. The deburring job is easy on the top of the guide and can be done with another drill bit held by hand and turned to lift off the burr. The inside of the waveguide may be done with a very small bladed knife such as an X-acto® scalpel. This can also be done from the top of the waveguide by inserting the point into the hole against the burr.

Clean a piece of copper pipe (shown in the assembly drawing) as the cavity cylinder. It should be free from all burrs on each end and polished clean with Dutch Cleanser or a similar pot-scouring compound, particularly on the inside of the cylinder. On one end of the cylinder, using a machinist's square and try, set the center so that a pair of marks can be scribed across the open face of the cylinder and on the end of its side walls.

Using flux here, too, solder the half-circle of brass in place so that it lies on the two scribe marks just made to the bottom edges of the cylinder. Now the bottom of the cavity will be half closed. Use acid-base soldering flux for this operation.

The cavity may now be mounted to the waveguide section by aligning the scribe marks on the cavity outside walls with the scribe line made on the face of the waveguide. The half circle of brass will butt against one side wall of the waveguide providing a solder surface. Using a C-clamp and a small, flat piece of wood, clamp the cavity in place, placing the wood under the clamp so that it does not mar the top of the cavity. Adjust the cavity so that it aligns with the marks on its walls and the waveguide. Make sure that the half-circle butts tightly against the side wall of the waveguide. Now apply soldering paste to the bottom of the cavity and to the waveguide surfaces that make contact with the cavity parts. Heat and solder, using just enough solder so that it will "run" when the assembly is hot enough. Let the assembly cool thoroughly before removing the clamp.

When the soldering is completed, the waveguide section should have the cavity mounted off-center on the guide with the iris hole off-center with the diameter of the cavity (see Fig. 3 details). The cavity should be in line with the scribe marks previously described as the alignment lines. If this is not the case, but the alignment marks are only a very few thousands of an inch off, do not rework to improve the alignment; this small deviation will not degrade the operation of the wavemeter too badly. Inspect the inside of the cavity where it mates with the waveguide and be sure that solder has completed the "run" around the entire cavity surface that is in contact with the waveguide.

When all soldering is complete on the waveguide and cavity body, wash off all soldering paste with very hot water. Any traces of the paste or acid will degrade the future performance of the instrument when it causes corrosion.

The most important parts of the assembly are attempted next. These parts are shown in the mechanical drawings as parts A through D and should be assembled in this order. (Before assembly, if you desire to silver-plate all parts of the cavity and waveguide, some improvement of the cavity Q will result and the performance of the wavemeter will be better. Silver-plating *can* be dispensed with, however, since the unit will perform very well without it.)

Now the tuning disk and lead screw can be assembled into the bearing and collet assembly. To do this, place a lock nut of the compression type (as found on most screwdriver-adjust locking pots) on the collet—see A in Fig. 3. The locking nut is a device which has inside tapered threads, 3/8-24, and is about 1/4-inch thick. It will compress the collet against the lead screw threads causing it to move tightly in the collet bearing. Put the nut on so that it is loose.

Now, from the opposite side of the bearing plate (A), insert the threaded end of the brass 1/4-inch rod and screw it up through the collet until about an inch of it is exposed. This item is labeled B in Fig. 3. Now install piece C, the tuning disk, on the end of the brass-threaded rod. Gently heat this piece and solder it to the threaded rod, taking care not to get solder in the fine threads. When the piece is cooled, wash off all solder paste. Now, on the back of the tuning plate, add the powdered iron as described earlier.

When the three pieces have been assembled, insert the tuning plate into the cavity and align the top plate so that the three

Photo B. Wavemeter parts and bottom view of the cavity, showing how it is offset from the waveguide.

screw holes in the cavity wall top mate with the three threaded holes for the three 4-40 flat-head screws, which can be found on the side of the top plate (A). Press the top plate down firmly into the cavity and install the screws to hold the plate firm.

Now screw in the tuning plate by adjusting the threaded rod; see that it moves in and out of the cavity easily, and adjust the collet lock nut so that the rod moves firmly but not hard. Now put a dab of Super Glue® on the lock nut, taking care not to get it in the cracks of the collet and on the lead screw threads. This will lock the collet lock nut in place.

Now the last piece, D, can be assembled. Simply glue the plastic disk to the top of the 1-1/2-inch diameter tube. This tube can be made from any available plastic or metal material. It fastens to the extended end of the threaded brass rod with two 1/2-36 nuts. Place one nut on the end of the rod and engage enough threads to allow about 1/4" to protrude through the assembled dial barrel (D). Then place another nut with the same threads on the rod and tighten until it is firm and the tube will not rotate. Now you have a micrometer barrel dial and a completed assembly. When rotated, it actuates the threaded lead screw and serves as a dial. It should move freely without touching the outside walls of the cavity. Cover the outside of this tube with a piece of paper. Also cover the cavity outside wall with white paper so that calibration marks can be added.

To calibrate the wavemeter you will need a signal source which can be tuned over at least the amateur assignment. Calibration points beyond the band on either end are a valuable asset and should be included. The source can be your uncalibrated X-band transmitter, a signal generator, or simply a klystron and power supply. A calibrated wavemeter and an attenuator ending in a crystal detector mounted in a waveguide adapter make up the waveguide components required for calibration. A meter to register the crystal current will serve as the reaction indicator. Fig. 4 shows how to connect these devices for calibration.

Let's assume you are using a klystron and power supply to do the job. Be sure that the klystron is oscillating in a mode that will not stop or "squeg" during the operation. Once it is oscillating, adjust the attenuator to provide a three-quarter scale reading on the current meter. Set the klystron so that it is in the range of 9.8 GHz to 12 GHz by adjusting its frequency control. Now adjust the calibrated wavemeter (which we will call the reference wavemeter from now on) until you see a pronounced dip in the output-current indicating meter. By adjusting the frequency control on the klystron and the reference wavemeter, you should be able to set up the starting calibration frequency of 9.8 GHz. When you have this frequency and you are sure of it, detune the reference wavemeter. Now tune the device you have just constructed until you get a similar reaction on the output-current meter. The dial barrel will be quite near the top of the wavemeter cavity. Now simply make a pencil or pen mark on the calibration dial paper, using the moving barrel edge as a guide for your pencil.

Continue the calibration process, setting the frequency changes in 50-MHz steps, for a start. Put the coarse calibrations on one side of the calibration line and fine steps on the other side. If you decide to make the calibration steps at a finer set of divisions after you have done a coarse calibration, do not remove the coarse steps; they can be your check points to check out how well the device resets.

The drawings showing the mechanical construction of the wavemeter are supplemented by photographs so that you can verify how the assembly goes together. It is not difficult, and most amateurs who have had experience with hand tools should be able to complete the unit satisfactorily. It is hoped that the meter will be helpful to those amateurs who want to know that they are within the X-band confines.

To use the wavemeter in your rig, simply place it in the waveguide circuit, which is the output toward the antenna, then tune it until you get a reaction in your power-output indicator, read off your frequency, and then detune the wavemeter. You may leave it in the line since it will cause very little loss to your output.

Materials for this device were obtained from Lectronic Research Labs, Inc., Atlantic and Ferry Ave., Camden, New Jersey. All of the materials for waveguide components are listed in their catalog. There are numerous other sources of material for this band and others, but this catalog should be in the hands of all microwave enthusiasts.

All letters with questions regarding this and other articles I have written will be answered if the writer includes an SASE. All telephone calls also will be answered, but please remember what your time zone is so that I don't get your call in the early hours of the morning. ■

The Real-World Connection

—add up to four I/O ports to your TRS-80

When I recently acquired a TRS-80, the first device that I wanted to interface to it was my music synthesizer (*73 Magazine*, November, 1978). It requires three output ports. Unfortunately, there is no inexpensive, commercially-available way to provide I/O for the TRS-80, but a home-brew device is easy to build and not at all expensive. A version with one input port and one output port costs about $22 (not including the unregulated power supply). Each additional port, up to a total of four of each kind, costs about $2.50.

Fig. 1 is the schematic of such a one-input/one-output device (easily expanded as described later).

The TRS-80 points to an I/O device by means of address lines A0-A7. The six more significant of these lines drive the select and enable inputs of a 74LS138 one-of-eight decoder. The Y0 output of the 138 is low whenever 1000 00XX appears on A7-A0. This output drives the enable inputs of

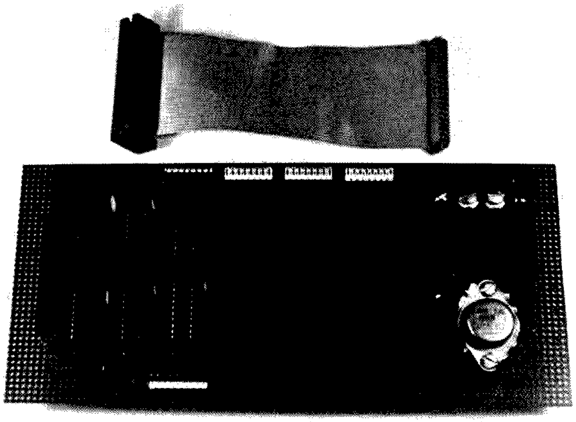

Photo A. Interconnect cable and top view of a wire-wrapped I/O board. The 2 × 20 header at the left accepts one end of the interconnect cable. The other end of the cable attaches to the connector at the rear of the TRS-80 keyboard unit. The 2 × 8 (output) and 2 × 9 (input) headers provide connections to the I/O ports. ICs (starting at upper left, clockwise) are a 74LS138, 74LS155, 74LS374 (output), 74LS374 (input), 74LS368, and 74LS368. Empty sockets are for additional (subsequently added) output 74LS374s. Terminal strip provides connections to unregulated power supply. LM309K regulator and tantalum capacitor are at lower right.

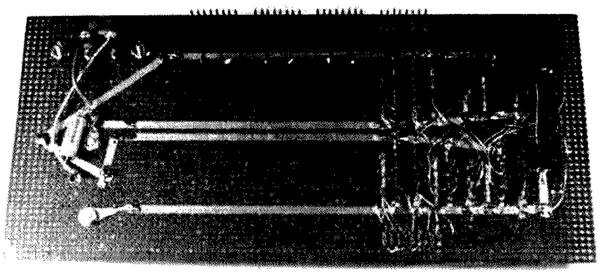

Photo B. Bottom view of the I/O board. The 2 × 20 header is at the right. The electrolytic and ceramic capacitors for the regulator circuit are at the left. Power buses are 1/8″-wide adhesive copper strips made by Circuit-Stik™. Small white spots are paint used to mark correct positions for the sockets and headers. Terminating resistors (input port) were added after the photograph was taken.

a 74LS155 dual two-line-to-four-line decoder, while address lines A0 and A1 drive the select inputs, and the $\overline{IN}$ and $\overline{OUT}$ lines each drive one of the data inputs of the 155. The $\overline{IN}$ line must be inverted since the 1C data input of the 155 is itself inverting. The net result at the outputs of the 155 is a set of four $\overline{IN}$ strobes and a set of four $\overline{OUT}$ strobes, each of which is completely decoded and which correspond to device numbers 80, 81, 82, and 83 (hexadecimal).

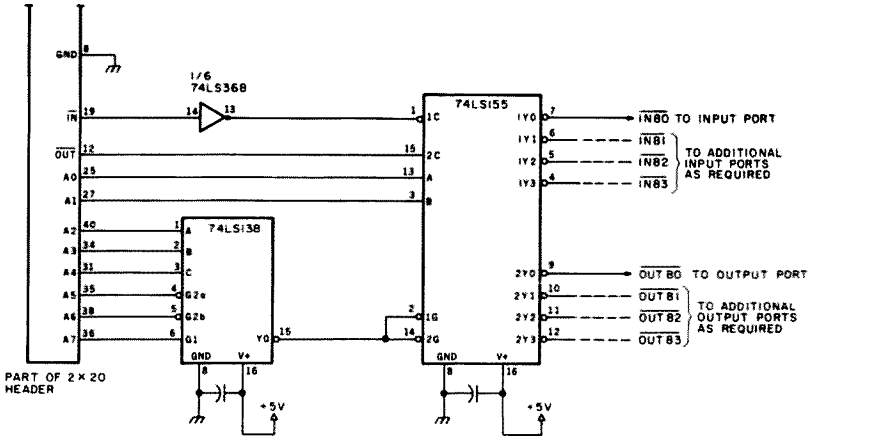

Fig. 1. Schematic of strobe generator circuit. Unmarked capacitors are 0.1-uF, 25-volt disc ceramic.

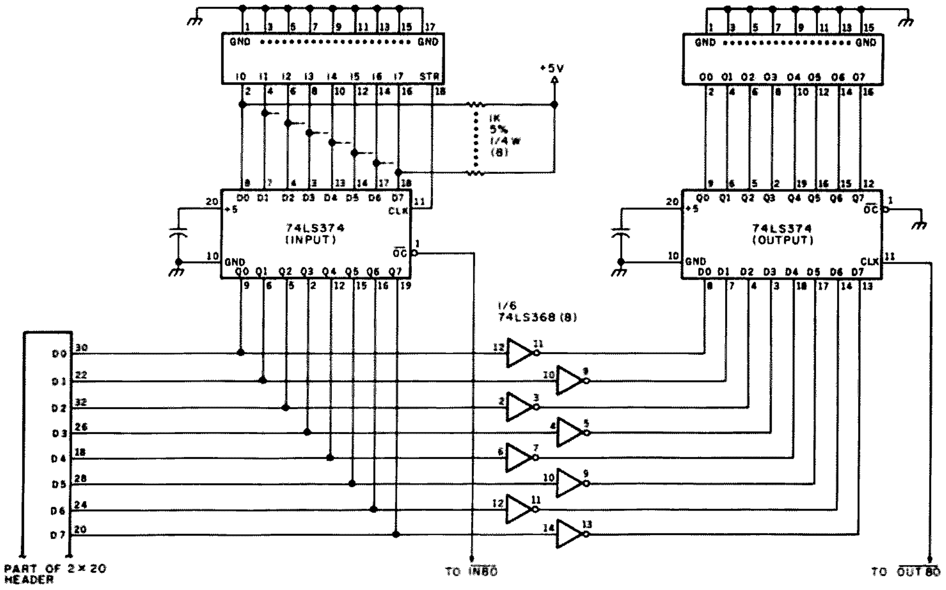

Fig. 2. Schematic of port function circuit. Unmarked capacitors are 0.1-uF, 25-volt disc ceramic. Tie enable inputs (pins 1 and 15), unused data inputs (pins 2, 4, and 6), and ground pin (8) of the 74LS368s to ground. Tie +5-volt pin (16) of each 74LS368 to +5 volts and bypass to ground via a 0.1-uF, 25-volt disc ceramic capacitor.

The 74LS374 is a good choice for the port functions proper. It is a positive-edge-triggered (CLK input) octal D flip-flop with tristate outputs that are enabled via the $\overline{OC}$ input. When the 374 is used as an output port, the data lines from the TRS-80 drive its D inputs (via buffers), one of the $\overline{OUT}$ lines from the 155 drives its CLK input, and its $\overline{OC}$ input is tied to ground. Note that data from the 74LS368 buffers is inverted. Using 74LS367 buffers avoids this since they are non-inverting, but at the expense of an extra IC to provide the inverter for the $\overline{IN}$ line.

Adding another output port simply involves connecting another 374 to the buffer outputs and using one of the remaining $\overline{OUT}$ strobes to drive its CLK input.

When the 374 is used as an input port, its outputs drive the data lines to the TRS-80 and one of the $\overline{IN}$ strobes from the 155 drives the $\overline{OC}$ input of the 374. The clock and data inputs of the 374 provide the port function. Substituting a 74LS373 for the 374 provides a tracking (rather than clocked) input. The outputs of the 373 track its inputs as long as its CLK input is held low.

Adding another input port simply involves connecting another 374 (or 373) to the data lines and using one of the remaining IN strobes to drive its $\overline{OC}$ input.

Photo A shows the connector cable and the top of a wire-wrapped I/O board which provides one input port and four output ports. The connector cable shown is made of junk-box parts. An AP Products 924005-6R socket/jumper (Jameco Electronics) and an AMP 88103-1 card edge connector (several sources) provide an easily-obtained alternative. The card edge connector mates with the PC fingers on the TRS-80 keyboard unit, while the socket/jumper connects to the 2 × 20 header on the

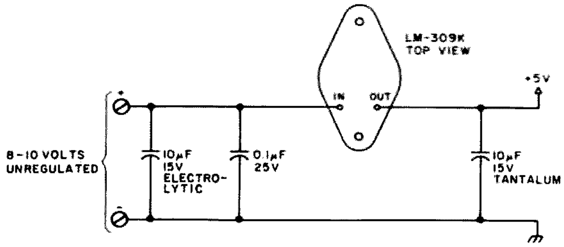

Fig. 3. Schematic of power-supply regulator. The 10-uF capacitors are tantalum and electrolytic; the 0.1-uF capacitor is disc ceramic.

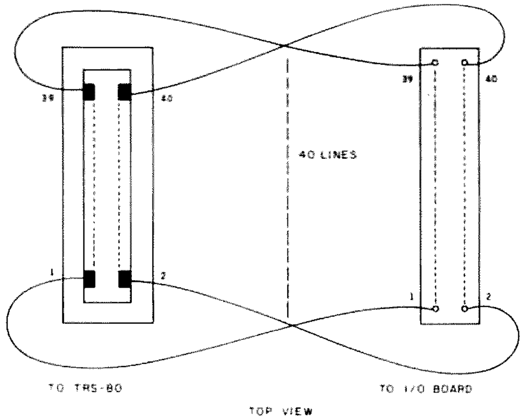

Fig. 4. Schematic of interface connector. Viewed from the rear of the TRS-80, pin 1 is the upper-left finger and pin 40 is the lower-right finger on the PC board.

I/O board. The connection to each port is via a 2 × 8 (output) or 2 × 9 (input) header.

Photo B is a shot of the bottom of the I/O board taken during construction. It shows the copper-foil bus strips which carry power to the ICs, but not the 1k terminating resistors which were added later.

Building the board required only three evenings, including one just to set up the epoxy which holds the sockets and headers to the perfboard. In operation, the board has been glitch-free. For the time and money involved, it can't be beaten. ■

Practical Af and Rf Speech Processing

—using modern ICs

The value of speech processing at either the af or rf levels for SSB transmitters has certainly been discussed and presented in many forms. However, some readily available and inexpensive ICs well suited to speech processing applications are still overlooked by many amateurs. These are the English line of Plessey ICs which are distributed also in the U.S.

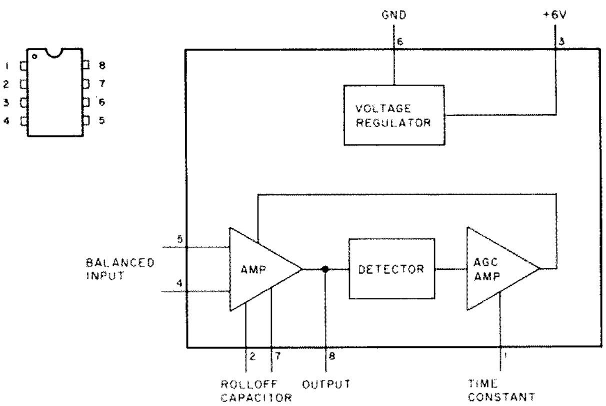

Fig. 1. Internal stages in the Plessey SL1626C af compressor.

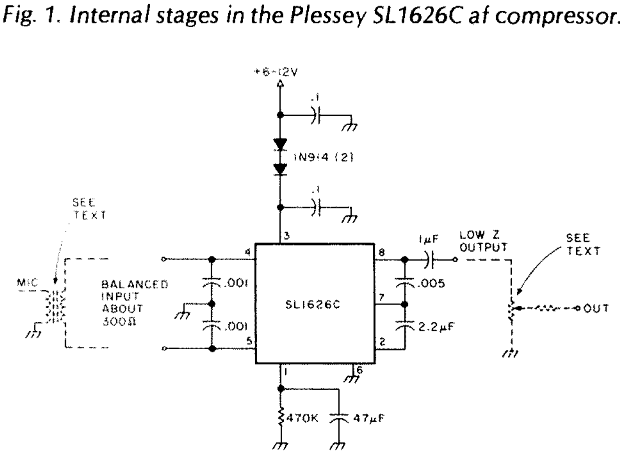

Fig. 2. Complete circuit of the af compressor with optional input transformer and output-level control. If the circuit is powered by a 9-volt transistor radio battery, the battery should be bypassed with a 100-uF, 15-volt capacitor.

Perhaps the most interesting IC yet developed for use in an af speech compressor is the Plessey SL1626C. A block diagram of the small, eight-pin IC is shown in Fig. 1. The input stage is a balanced one with a low-impedance input of about 300 Ohms. Part of the output (low impedance at about 50 Ohms) drives a detector stage which, in turn, drives an agc stage which regulates the gain of the input amplifier. A very wide control range of 60 dB can be achieved (100-uV to 100-mV input) over which the output will remain essentially constant. By the use of a small transistor-type matching transformer at the input, almost any low- or high-impedance microphone can be used with the IC. Supply voltages between 6 and 12 volts can be used with the unit, drawing about 14 mA at 6 V.

A few simple external components are all that are needed to implement a practical circuit. The low-frequency rolloff response of the compressor is set by a capacitor connected between pins 2 and 7. A 3-dB point at about 100 Hz is achieved by using a 2.2-uF capacitor, for example, although the value can be adjusted as desired for higher frequency rolloffs by reducing the size of the capacitor. The high-frequency rolloff response depends on the value of a capacitor connected between pins 7 and 8. A .005-uF capacitor provides a 3-dB point at 3 kHz, but one can vary this capacitor value also to achieve the best speech response with a given microphone.

The agc time constant is set by a parallel resistor/capacitor combination connected from pin 1 to ground. The attack time is set by the capacitor at 0.4 milliseconds/microfarad. The decay time constant is set by the time constant of the combined resistor/capacitor combination. The resistor and capacitor values can be varied to suit individual preferences, but the manufacturer recommends that the resistor value be between 500k and 1.5 megohms and that the capacitor be not less than 22 uF.

A practical circuit using the SL1626C is shown in Fig. 2. In addition to the resistor/capacitors mentioned previously, several other capacitors are used for rf bypassing. A balanced input is shown, although a

single-ended input can be used at the sacrifice of some of the control range. In general, it is better to use a small input transformer of the transistor-interstage type. These transformers are inexpensive, and a 500/50k-Ohm type will suffice for most high-impedance microphones, while a 500/10k-Ohm type can be used with medium-impedance microphones.

There are no adjustments to make and the circuit will work very well in most applications with the component values shown. The one exception might be in a mobile application where the large dynamic range of the circuit might cause excessive background noise pickup during speech pauses. This problem can be cured by also placing a resistor between pins 7 and 8 to reduce the dynamic range. Resistor values of about 500 to 1,000 Ohms should be used, reducing the dynamic range to 35-40 dB. A 1k potentiometer may be connected on the output if it is desired to have a variable-output control. A series resistor may also be placed in the output line, if necessary, to reduce loading on the stage that the compressor works into. For instance, if the output of the compressor goes to a high-impedance microphone input on a transceiver, a series resistor of 50k to 100k may be necessary.

A parts layout for the SL1626 circuit is shown in Fig. 3. While there is nothing critical about the wiring of the circuit, a good, compact layout with good grounding will contribute greatly to avoiding any rf feedback problems from this high-gain circuit. Single- or double-sided PC board construction or use of the isolated-pad technique are particularly recommended. There are so few interconnections involved that isolated-pad construction is just as fast as etching a board, and this technique leaves almost all of the copper on the board for a good ground plane.

For those not familiar with the technique, it just involves the use of a special drill that simultaneously drills a hole in the PC board for a component lead while removing a small ring of copper around the hole for a small radius so that one can interconnect component leads without shorting to the remaining copper. The same effect can be achieved using regular drills—a small one for the component lead hole and a larger one to cut the copper away around the hole. A small modeling knife is handy in removing the copper so that there are wiring channels, where necessary, between component holes. I have used this technique for dozens of small projects with good success. It has all the electrical advantages of an etched board with almost the ease of construction associated with plain perforated board stock.

The af speech-compressor circuit just described is easy to implement and does provide some added audio "punch" with almost all transceivers. Probably, on the basis of the investment necessary in terms of money and constructional complexity, it provides the best return in terms of increasing a transceiver's effectiveness. However, numerous tests have shown that clipping at the rf level is still more effective. Completely outboard devices can be constructed to obtain the benefits of rf clipping where an SSB signal is generated, clipped, filtered, and then demodulated to provide an audio signal to a transceiver. The most economical way to provide the benefits of rf clipping, however, is to break the SSB generation chain in a transceiver, as shown in Fig. 4, and insert a few additional stages for clipping, amplification, and filtering. Some of the Plessey ICs make this particularly easy to do.

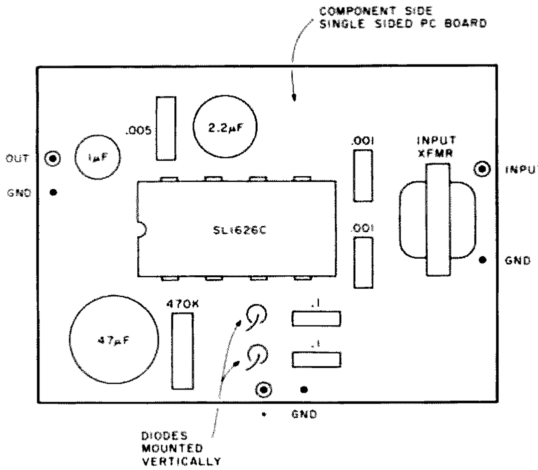

Fig. 3. A typical parts layout for the af compressor. The layout is exaggerated, of course, but any similar layout where the input/output is kept well separated will suffice.

The Plessey SL610C is an integrated rf amplifier having a modest voltage gain and a bandwidth up to 140 MHz. The supply voltage can be 6-9 volts, and the current drawn is about 15 mA. Internal HF decoupling is provided and the external circuitry needed is very simple. In fact, if agc is not applied to a stage using the SL610C, there is no need for any external circuitry other than an input/output coupling capacitor or a tuned circuit, if desired.

The Plessey SL613C is a broadband limiting amplifier consisting of a two-transistor amplifier stage, the output of which drives an emitter-follower output stage. Negative feedback is incorporated and careful design of the bias and feedback circuitry ensures that the amplifier limits or clips symmetrically. The limiting action starts with about a 120-mV input. The amplifier, like the SL610C, has internal HF decoupling so that the external circuitry needed is simplified. The circuit can operate on 6-9 volts and draws about 15 mA.

The two ICs just described can be used to form a simple but very effective rf signal processor (clipper) as shown in Fig. 5. This circuit, of course, is meant to be used in the scheme shown in Fig. 4. It can be

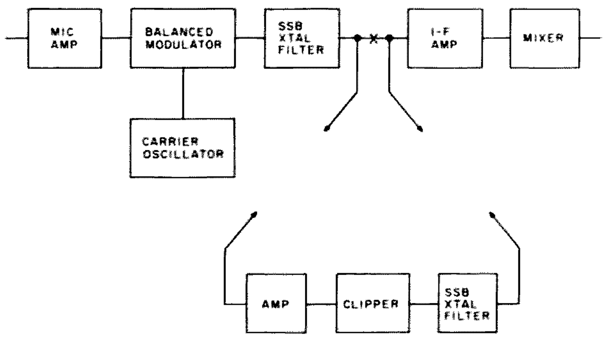

Fig. 4. Rf clipping can be added to most SSB transceivers by breaking the i-f chain after the SSB filter and adding the stages shown.

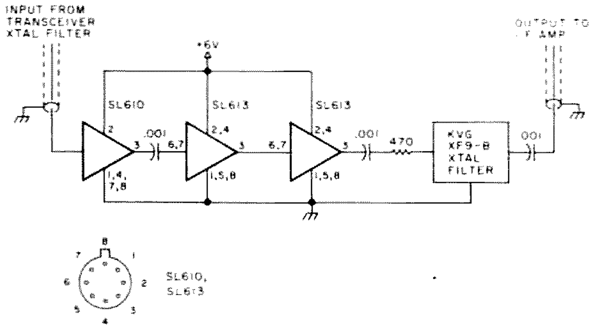

Fig. 5. Extremely simple but high-performance rf-clipper circuit shown with a 9-MHz crystal filter.

adapted to practically any transceiver i-f, although the circuit as shown uses a sideband filter for a typical 9-MHz i-f where the upper-sideband crystal frequency would be 8998.5 kHz, and the lower sideband crystal frequency would be 9001.5 kHz.

The KVG crystal filter shown is a West Germany product distributed by Spectrum International, Box 87, Topsfield MA 01983. It can be used with many 9-MHz i-f transceivers although, if possible, the best thing to do is to purchase a duplicate of the sideband filter used in any given transceiver.

The circuit, as can be seen, is extremely simple. The input signal is amplified by the SL610C stage and fed to two cascaded SL613Cs. The latter two stages clip the signal but, because of their inherent symmetrical clipping, preserve the zero-crossing points. The harmonics and higher-order intermodulation products are removed by the following crystal filter.

The mean-to-peak ratio of an unprocessed SSB signal can be increased by up to 12 dB. Although it is exactly this increase that makes rf speech processing so effective, you have to be sure that the output stage and power supply in a transceiver can take the extra average power dissipation. There is no way to be absolutely sure of this beforehand although, if the SSB and CW power-input ratings of a transceiver are drastically different (the CW input being lower), you should proceed with caution. This is not true of most newer transceivers, but mainly of some older types using sweep-tube finals.

The circuitry of Fig. 5 can be assembled on a small PC board. Again, the isolated-pad type of construction is recommended since there are so few interconnections and components involved. Short lengths of coaxial cable are used to connect the input/output into the transceiver circuitry, and a small DPDT relay can be incorporated to provide the ability to switch the clipper in or out of the transceiver circuitry. If you are wondering why there are no bypass capacitors, etc., remember that HF decoupling networks are *internal* to each IC.

The Plessey units are distributed nationwide; I have purchased units from Ancroma Corp., PO Box 2208, Culver City CA 90230. However, if you cannot locate a source of supply, write directly to Plessey, 1641 Kaiser Ave., Irvine CA 92714, for the name of the nearest distributor. ■

LOR: A Light-Operated Relay

—handy circuit has many uses

The problem: how to turn on a cassette recorder whenever a certain 2-meter channel was active, without digging into the crowded circuitry of a Yaesu 227?

A channel busy light provided the answer: a light-operated relay (LOR).

The circuit is simple. A 2N5778 phototransistor, amplified by an NPN transistor (I used a BC-108) controls an NE555 IC timer. The timer drives the reed relay and prevents the recorder from stopping between transmissions, so the first word or so is not missed or slurred.

The circuit was ready to try out after only a few minutes at the breadboard. I cut, drilled, and bent 90 degrees a thin aluminum bracket to hold the phototransistor in front of the channel light. The microphone plug nut held the bracket to the panel. A piece of ¼-inch black plastic tube shielded the phototransistor from stray light.

I then got the idea of using the relay to key a second transmitter on another channel to make a repeater. An audio output transformer matched the four Ohms from the Yaesu's audio out jack to the microphone input of the second unit. The timer could now be adjusted to control the length of the squelch tail.

Several of these LORs have been built, all with good results. Layout is not critical: Printed circuit board, breadboard, chassis, or "dead-bug" construction all work well. Dead-bug is when the IC or transistor is fixed to the board with its legs pointing up. The .001-uF capacitors suppress any false triggering due to stray rf. The only caution is to use a good quality timer capacitor for C1. Most electrolytic capacitors differ a lot from the value on the label. Try several.

Do not forget the diode on pin 3 of the NE555; otherwise, the relay may latch.

Adjust the time by R1 to suit your needs. The sensitivity must be adjusted to a minimum working position to prevent false triggering by stray light.■

The Calibrator Gater

—so you can find yourself

Ever had trouble picking your calibrator signal out of the heterodynes and QRM on the HF bands? Does your calibrator poop out on 15 and 10? How about giving it a little personality to make it stand out? This circuit does just that. It switches your calibrator signal on and off rapidly, giving it a distinctive sound that is easy to find in even the thickest of crud. It is simple, cheap (about $3 with all-new parts), easy to install on just about any receiver or transceiver, and leaves no irreversible modifications. About the only thing it ain't is original; Ten-Tec has had a similar feature on its Triton models for some time. However, if you don't own a Triton, why not give this circuit a shot?

The circuit, in keeping with personal tradition, is simple. It consists of a CMOS quad gate connected as a low-frequency oscillator which drives a CMOS quad bilateral switch. This switch is connected between the calibrator output and the antenna input to the receiver and serves to pulse the calibrator signal rapidly, making it sound different from most other racket present on the band. Since CMOS circuits work satisfactorily over a 3-to-15-V dc range of supply voltages, locating a suitable power tap-off point in the rig shouldn't be much of a problem. On tube-type rigs, the half-wave rectifier and filter capacitor shown will allow the circuit to be operated from an ac tube filament or pilot-light wire. Most transistor and hybrid rigs already have a suitable dc supply built in. That's why the rectifier is shown separate (but still included in the $3 price tag). Use it if you need it.

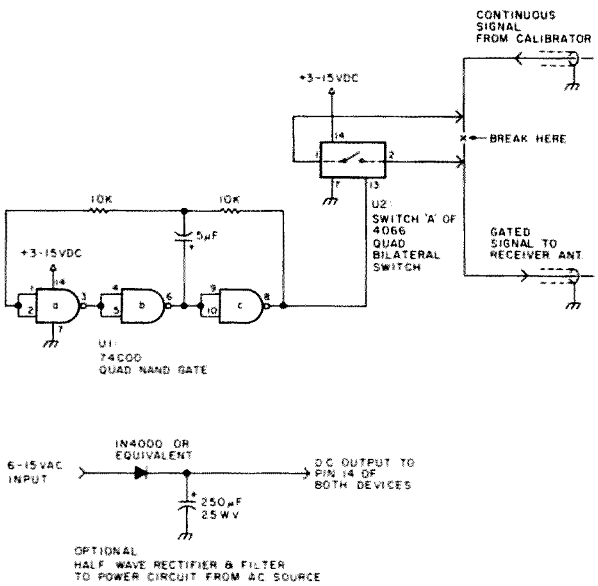

Fig. 1. The Calibrator Gater.

Construction is non-critical. Both CMOS devices are static-protected, so unless you barbecue them with a 150-Watt radiator-shop special, the circuit should work no matter how much you torture it. Use a short piece of wire between the circuit and the calibrator and again between the circuit and the receiver antenna input, or else use miniature coax to prevent any instability or stray coupling caused by the modification.

On my HW-101, the device was built on a 1" by 1½" piece of perfboard and allowed to hang by its wires under the bandpass circuit board. Connections consisted of merely unsoldering the center conductor of the coax (antenna input) leaving the bandpass board right after CR201 (calibrator output) and connecting one wire of the CMOS switch to the coax and the other wire to the spot where the coax had been on the board. Ac power was taken from pin 4 of tube V19 and was rectified by the circuit shown. Incidentally, it doesn't matter which wire of the CMOS switch goes to the calibrator or antenna input; it works just fine either way.

Most calibrators don't run continuously, only when they are needed. Thus, unless you have an oddball, no power switch is needed for the circuit. Current consumption is negligible, even for the QRP fan. With the calibrator turned off, the switching action of the device is unnoticeable under normal conditions. However, at full rf and af gain with no antenna connected, a distinct clicking sound is detectable. If this should become noticeable

with an antenna connected, a switch for the circuit will have to be added (not included in the $3 price tag, since anyone with a receiver or location *that* quiet doesn't deserve to pay less than $3).

According to the *CMOS Databook*,[1] the 4066 quad bilateral switch is capable of passing signals up to 40 MHz with little attenuation, so that takes care of all calibrator harmonics for the HF bands. Due to the conservative nature of many CMOS specifications, it is very possible that the circuit would work at six meters, or even two meters with a simple preamp after the switch, although that's just speculation.

So I conclude this article with a couple of thoughts for the experimenter. First, if the frequency at which the calibrator is gated doesn't suit you, here's the formula to change it:[2] Frequency (in Hz) desired = 0.599/(R × C), R being in Ohms and C being in farads (multiply microfarads by 1,000,000 to get farads). Note that R is either resistor, as long as both are equal.

Also, since only one of the four bilateral switches is used in this project, why not leave some provision for using the other three? They're dandy for switching in audio or CW filters, speech processors, extra phone-patch or microphone inputs, various metering modifications, or for just about any low-level audio or rf application where the signal voltage doesn't exceed the voltage on pin 7 of the 4066. ■

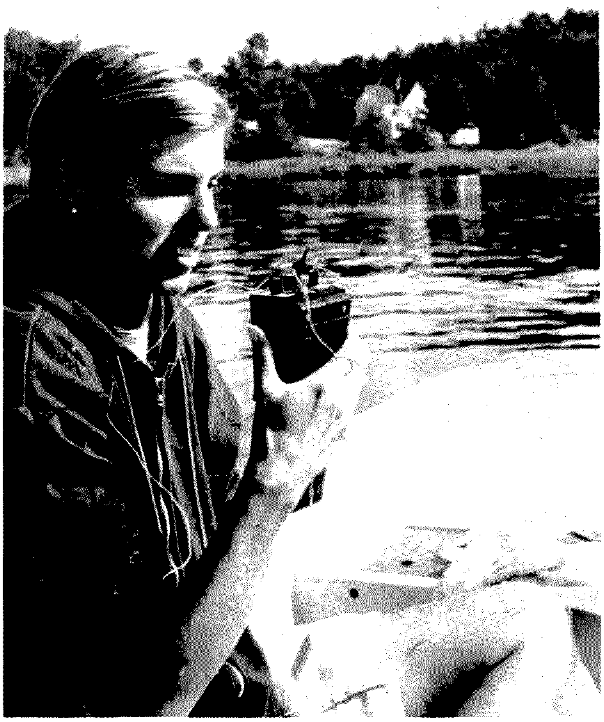
The Flexi-Plane Antenna

—this "scrawny ducky" will boost your HT's signal



On the lower Kennebec River near Bath, Maine, the XYL of N1PL talks through the Streaked Mountain repeater (.28/.88), some 70 miles away from the floating QTH.

Do you have a 2-meter handie-talkie? Where and when do you use it? If you're like me, you probably find yourself with unit in hand in a variety of circumstances. You may be chatting across a hamfest on .52, trying to make a distant repeater from a mountainous site you have arduously attained, or coordinating a civil-defense drill. What do you use for an antenna?

The Rubber Duck

For general toting and flea-market work, the flexible rubber ducky makes a fine antenna. It is shorter than a quarter wave and will not break off if you should accidentally sit down with the little rig in your back pocket. But with flexibility comes a drawback: The wobbly ducky just doesn't put out the juice. A friend told me that the rubber ducky was down 6 dB—but he didn't say down from what.

My own measurements, using a home-brew field-strength meter calibrated at 146 MHz (by comparing readings to those at several power levels from my Sigma RF-2000 power meter), suggest that the signal from the rubber ducky is down more than 3 dB compared to the signal from a ground plane. Field-strength measurements were taken at 20 meters (65.5 feet), or roughly 10 wavelengths.

That 3 dB difference (or more—measurements were conservative) means losing *half* of your transmitting signal strength, and also *half* of the strength of the signals you receive. Not so good. Do you want to stick to that rubber ducky?

What Alternative?

Surely, you won't want the ducky for mountaintopping. You might as well use a small beam there, since you're already going to the trouble of hauling your body up. However, I find that much of my handie-

talkie use is of the mid-range variety. I am often 20 to 60 miles from a repeater and, depending on repeater coverage, access is marginal with the rubber ducky.

What I did was build an antenna which combined the advantage of the rubber ducky (flexibility) with the relative gain of the ground plane. The Flexi-Plane is actually more flexible than the duck—and a good sight cheaper!

I made mine for the cost of a connector. I also used some copper wire that I had in the shack. (Don't use aluminum, because it's brittle and won't solder.)

How To Build It

Like any ground plane, the Flexi-Plane consists of a quarter-wave radiator and an artificial ground plane of quarter-wave radials. I made the radiator of #18 copper bus wire cut to a length of 0.49 meters (19.3 inches). For the radials, I used two lengths of #22 solid copper hookup wire about one meter (39 inches) long.

I put the end of the center radiator through a short piece of insulation stripped from a bit of zip cord. Then I pushed the wire and insulation down into the center of the BNC connector, soldered the wire to the small pointed tip, and, to hold things in place, poured some plastic rubber into the top of the connector.

Next, I stripped some insulation from the center of the hookup wire radials, wrapped each wire around the connector, and soldered them in two places. Thus I had four radials, each about 0.49 meters long. Of course, a connector other than a BNC might require a slightly different procedure.

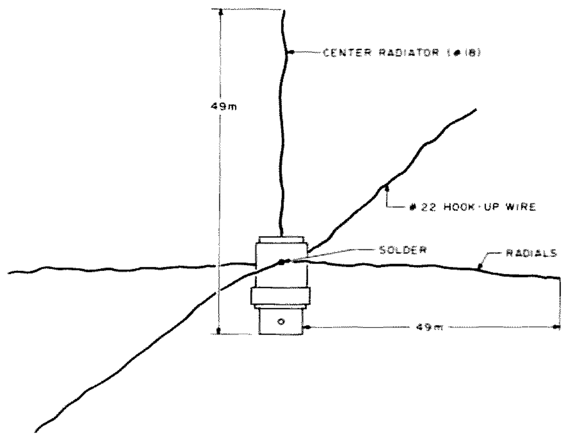


Fig. 1. The Flexi-Plane with BNC connector.

Not Pretty, But Beautiful!

The resulting antenna isn't handsome. But it is highly flexible. You can roll it into a ball or roll it around the rig. (When you unroll it, the elements don't have to be arrow-straight, so don't worry!) In three years, my Flexi-Plane has been all over the country and has spent many hours in my boat in Maine with no deterioration.

Best of all, it combines what all hams strive for in an antenna, the ability to produce a strong signal, with what my brother, Koof W3KF, finds especially beautiful in a home-brewed item—cheapness! ■

CB to 10. . .and Beyond

—getting excited at 432

Shortly before the January VHF contest, a commercial 432-MHz transverter was purchased as a last minute attempt to add another potential source of points to the station. However, the station's only HF transceiver was already providing the necessary 28-MHz drive for a pair of 6- and 2-meter transverters. In order to provide for independent operation and monitoring on 432, another 10-meter transceiver would be required (preferably solid state in keeping with the rest of the station).

After purchasing one tower, several transverters, a truck load of aluminum for antennas, and miscellaneous other items, to bring home another "radio" would have meant instant divorce court and possible damage to the operator! Enter—one solid-state, 23-channel, SSB, neglected CB rig, vintage 1973.

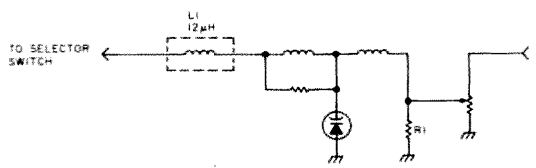

Fig. 1. SBE-12CB clarifier circuit. L1 is added to extend range to 15 kHz. R1 is 1-4k Ohms and controls linearity. All other components are existing.

The unit available for conversion was the SBE Sidebander II (model SBE-12CB). Conversion is simple and inexpensive and requires only a VTVM and wattmeter (with a 10-Watt slug) as test equipment. The actual conversion consisted of:

1. Replacement of four crystals in the synthesizer.
2. Addition of one inductor in the clarifier circuit to provide for continuous coverage.
3. Retuning the rig for 28-MHz operation.

The SBE-12CB uses three oscillators and a total of eleven crystals to synthesize its 23 channelized frequencies. A fixed 7.8-MHz oscillator is controlled by a single 7.8025 crystal. This oscillator remains unchanged. The other two oscillators, 7 MHz and 11 MHz, are controlled by four and six crystals respectively. The channel selector switch selects one (out of 4) crystals from the 7-MHz oscillators and one (out of 6) crystals from the 11-MHz oscillator.

For LSB and AM conversion, the selected outputs of the 11-MHz and 7-MHz oscillators are added tc produce a signal around 1ʕ MHz. Adding the fixed out put of the 7.8-MHz oscil lator produces the requireı frequency. For USB conveı sion, this same 19-MH signal is added to the seı

	7.5025 MHz	8.5400	9.0400	= X5

Table 1. SBE-12CB synthesizer mixing scheme.

ond harmonic from the fixed 7.8-MHz oscillator (15 VHz) to produce a signal in :he 34-MHz area. Subtracting the output of the 7.8-MHz oscillator from this urn yields the required JSB frequency. Table 1 ummarizes the synthesizr.

The first column of Table indicates the frequencies vailable from this rig for B operation. All that is reuired to shift these frequencies into the 10-meter and is either to replace the x 11-MHz crystals or the ur 7-MHz crystals. Since ur is cheaper than six, the MHz oscillator was atcked. The new crystal lues are determined by king the new center freiency, subtracting the exing center frequency, and ding this difference to value of the existing MHz crystals.

Example: The new de-ed channel 1 frequency is 005 MHz and the old freency is 26.965; the difence is 1.040 MHz. The current 7-MHz crys- is 7.4625 MHz; add the ference (1.0400), and the v crystal required is 025 MHz = X2.

ince there is a greater jump between channels 3 and 4 for CB operation, the last 7-MHz crystal (X5) is .02 MHz greater than X4. X4, X3, and X2 are each 0.01 MHz apart. In order to provide for continuous coverage and more linear coverage, the new crystals were placed .0125 MHz apart in frequency. This reduces the final frequency coverage only slightly (2.5 kHz) and allows for continuous tuning, which was deemed a reasonable sacrifice.

Table 1 indicates the new crystals required for operation at 28 to 28.3 MHz, and also those required to operate in the phone portion of the 10-meter band (28.5-28.8 MHz). The actual coverage in each case is about 300 kHz.

The varactor clarifier of the SBE-12CB tunes ± 700 Hz from the selected center frequency. In order to provide for continuous coverage, a spread of about 15 kHz is required. Fig.1 shows the existing clarifier circuit in the unit plus the additional 12-uH molded choke (L1) which was added to extend the range to the required 15 kHz. Adding the choke caused the tuning range of the clarifier to vary in a nonlinear fashion, and it was found that R1 could be changed to rectify this situation. The new value of R1 is determined best by experiment and seems to fall in the range of 1 to 4k, depending upon the spread finally selected.

This completes the conversion. Retuning this rig is simple if you have the SBE service manual or Sams *Photofacts*® #CB-50 (described 1973).

The rest of the setup for 432 is simple enough. An attenuator was built to hold down the 12-Watt output of the CB rig on sideband to that required by the transverter. No preamp was deemed necessary for the SBE-12CB, but a 432-MHz one was utilized (see Fig. 2).

There is nothing unique about the 432-MHz utilization of this rig, but the conversion is an interesting project which can yield a low-cost, 10-meter mobile rig. ■

Newark DE 19713

Three-Way Power Supply

—ideal for CMOS, TTL, op-amp projects

For as long as I can remember I have wanted an inexpensive, self-contained positive and negative variable-voltage power supply for experimenting with transistors, digital, and linear integrated circuits. When National Semiconductor introduced their LM317 and LM337 adjustable regulators, I felt that this was the answer to my prayers. The LM317 and LM337 are the commercial-grade versions of the LM117 and LM137, which are positive and negative adjustable 3-terminal voltage regulators respectively, capable of supplying an excess of 1.5 Amps over a 1.2- to 37-volt output range. These two devices are easy to use, requiring only two external resistors to set the output voltage. They both also feature internal current limiting, thermal shutdown, and safe-area compensation, making them virtually blow-out proof against overloads.

This article describes the construction of a self-contained variable positive and negative regulated voltage power supply with an additional 5-volt supply for TTL integrated circuits, giving the final specs shown in Table 1.

The Circuit

As shown in Fig. 1, the power supply uses three integrated circuit voltage regulators: LM309, LM317, and LM337. The necessary positive and negative supply voltages are derived from the grounded center-tapped 25.2-volt transformer secondary and a full-wave rectifier bridge. After rectification, the positive voltage is filtered by C_1 while the negative voltage is filtered by C_4. For the positive supply, the output voltage is set by the 270 Ω resistor R_1 and the 5k Ω potentiometer. To improve ripple rejection, a 10-μF aluminum electrolytic capacitor C_2 is added across the 5k Ω pot. C_3 is added to improve the regulator's transient response. Diode D_5 protects the LM317 in case the output is shorted to ground. In a similar manner, the nega-

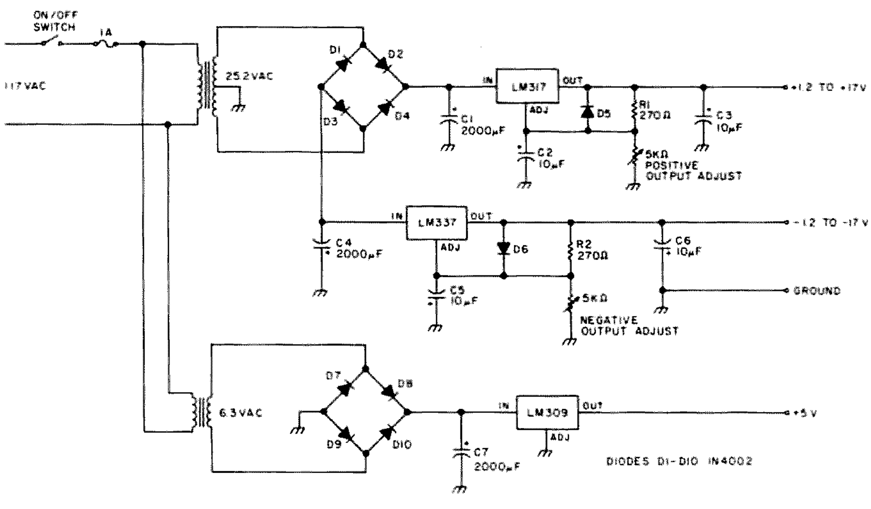

Fig. 1. Tri-voltage power supply schematic.

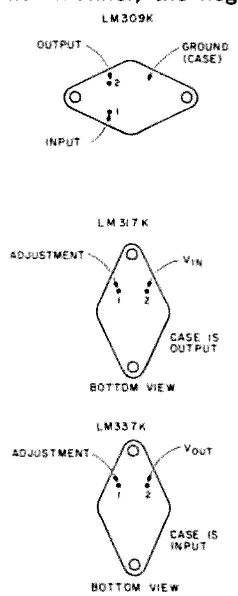

Fig. 2. Pin connectior for the LM309, LM31 and LM337 voltage reg lators (TO-3 packages).

tive supply is designed, except that the polarities of the capacitors and diode are reversed.

The 5-volt TTL supply section is of standard design, as described in many of the amateur radio and experimenter magazines.

Construction

Considering the number of components and the simplicity of the circuit, all connections were made with point-to-point wiring, keeping all leads as short as possible. Shown in Fig. 2 are the pin connections for the three IC regulators (TO-3 packages). Both the LM317 and LM337 must be insulated from the chassis. This is done by using insulating washers along with the required mica washer, such as the Radio Shack kit #276-1371. All controls and output jacks were mounted in an orderly manner on the front panel of an 8 x 5.5 x 3.75" metal cabinet (Radio Shack #270-269 or similar). As an additional feature, I included a pair of 0-15 volt dc edge-type panel meters that I had on hand. However, since meters of this type normally cost about $25 each, a lower-cost substitute is the 0-15 volt meter made by Radio Shack, #22-054, which sells for approximately $8. ■

	Positive Supply	Negative Supply	TTL Supply
Output Voltage	+1.27 to +17 V	−1.27 to −17 V	+5 V
Output Current	1 Amp	1 Amp	1 Amp
Load Regulation	0.1%	0.3%	50 mV
Ripple Rejection	80 dB	77 dB	80 dB

Home-Brew in the Real World

—victim tells all

Why is it that all the design projects in the ham magazines have titles like, "Build Your Own Station for Under a Dollar and a Half!" or, "At last! A Linear for Ten Bucks!" It seems as though every time I turn around, some designer has cooked up a homebrew project for me which will: a) give me everything I ever wanted, and b) won't cost me more than I would spend on a pound of solder.

My suspicion is that these guys do their pricing at their jobs. I have a picture, of, let's say, an engineer for some big electronics or digital company on his lunch hour, designing things for his ham shack at home. He breadboards them at work, grabs capacitors and chips out of handy bins, and doodles until he's happy with his final product.

The next thing we know, there's an article in *73/CQ/QST/HRH* entitled "DX the World for 75 Cents!" It is not my thesis that these folks are evil men who are trying to trick me into bankruptcy, but is the real world really full of people with $5,000 junk boxes? I wish I had a dollar for every article I've seen which is headed: "Here's a Weekend Junk-box Project That Will Give You Your DXCC in Ten Minutes!"

My junk box consists of some solder and a handful of parts that I couldn't find places for in my last Heathkit.® Worse than that, even, is that if the local Radio Shack doesn't have the part that is called for in the article, I have to mail away to Arizona or someplace that takes my credit card number and promises to bill me for postage.

Take the last home-brew project that I built from a magazine. It was a fifty-dollar frequency counter—that is, on the *page* it was a fifty-dollar frequency counter. But when the author called for *one* 100k resistor, I couldn't convince Radio Shack to sell me fewer than five at a clip. The only parts that I had on hand were the jumper wires. My phone calls alone, to Arizona to check on the errant parts, cost me almost fifty bucks!

Actually, my fifty-dollar frequency counter cost me —including the case ($2.19) and the presstype ($6.95) and the chips and all the good things inside the box —something like $80.00.

However, I wouldn't have it any other way. In truth, I am now the possessor of the world's best frequency counter. It is the best because I built it. I read the schematic, I figured out the mistakes in the drawings, I wired it up, and I saw its display light up. I enjoyed the smell of the rosin core the way a gigolo enjoys Chanel No. 5. I experienced the pride of showing off a homemade piece of equipment.

And I now have a lot of leftover resistors and capacitors and IC sockets because I was forced to buy more than one of each by the packagers. I think my junk box is getting bigger as a result. Who knows? In ten or twenty years I'll be able to build a RTTY system from the parts that didn't go into all my previous projects!

I guess if my XYL knew in advance that my fifty-dollar counter was going to cost eighty dollars, she would have pulled my credit cards.

It all works out for the best! ■

DXing the Past
—a visit to Signal Hill

For several years, my wife and I have been engaged in genealogical research into the origins of my wife's grandparents who moved from Newfoundland to Toronto around 1890. Our research could proceed no further without an actual visit to Trinity and St. John's, Newfoundland. The trip was of great interest to me from an amateur radio point of view. I had wanted to operate mobile from Signal Hill in St. John's since 1976, when I had walked up to the top of the hill to visit the Cabot Tower. Early in 1978, we had been in contact, on twenty meters, with both Newt VO1CW and Dick VO1EI about our interests and found that they had some knowledge of the families and places which were of interest to us. Gradually, the itinerary of a vacation pieced itself together, combining visits to Newt, Dick, Signal Hill, four or five small Newfoundland towns, and a few military museums. The last was to allow my son to pursue his interest in military uniforms.

In August, 1978, with the Kenwood TS-520 installed in the family wagon, operational on 10 and 15 meters, we drove via W1-, W2-, and VE1-land to North Sydney, Nova Scotia, and thence by ferry to Newfoundland. Band conditions were not particularly good, and we netted only 4 or 5 solid contacts per day until we were close to St. John's. Then a 5/9 QSO with G3MGW showed what ten can be like when it puts its mind to it, and later in the day we were working back home to Ottawa in a QSO with VE3KHT. Fifteen opened up as we drove into St. John's, with several contacts into G-land and one into OK-land. Then, having settled into our apartment hotel, we were off to Signal Hill.

As radio history buffs will know, it was here, in 1901, that Guglielmo Marconi carried out an experiment to demonstrate that signals could be transmitted by electromagnetic waves. On December 12th of that year, Marconi received three faint dots, transmitted from Poldhu in Cornwall, England: a distance of 1700 miles, and the first transatlantic DX.

Signal Hill is now a National Historic Park, and Cabot Tower, constructed in 1898 in commemoration of John Cabot's landing in Newfoundland 400 years before, is an old visual signal station. It now houses many exhibits, including details of the Marconi experiment. The parking lot next to the tower is an excellent mobile site—with a 360 degree clear view. The only drawback is its attraction for other hams and CB enthusiasts with resulting cross-modulation problems. Conditions were spotty to say the least, and although we made a number of contacts, DX and North America, in several trips to the Hill, there were only two real openings.

The first opening occurred late one evening. We had gone to the Hill at 2130 to take in the incredible view of the city of St. John's at night. We had been greeted with the typical hiss of a dead ten-meter band, and fifteen was just folding for the day. Just as we were about to leave, I gave one last sweep of the dial and, as usual at home, swept past the Ottawa ten-meter beacon, VE3TEN. But just a minute . . . what was VE3TEN doing with an S9 signal in VO1-land, hundreds of miles away? As always, ten had produced the unexpected—an opening to the west. A CQ netted a small pileup of W1s, W2s, and, finally, VE3KIE/3 and VE3TP from back home in Ottawa.

The second big opening, appropriately enough, was on our last day in St. John's. The family stayed in the apartment watching TV while I took one last trip to the Hill. Once again, at 2130 the fifteen-meter band was folding and ten sounded about as lively as a radio club meeting when the club president asks for volunteers. No sign of VE3TEN this time, but tuning over the CW portion of the ten-meter band, I came across a signal—perfect Morse at 30 words per minute. It turned out to be W1AW. Quickly swinging over to the phone band, I was just in time to hear WB1DMP signing off after a local QSO. A quick call to him, and he asked me to join him on the 10-10 Minute Man Chapter Net which was just starting. As a result, I worked those who checked into the net plus a few more W1s before the band faded as quickly as it had opened.

Our mission accomplished, the rest of the trip was devoted to genealogy, plus most enjoyable visits to VO1CW (being visited by his son, HS1ALT) and VO1EI. We had a couple of days of excellent mobile conditions on the way back home, and I was able to complete a long-standing personal goal—I now have operated from all Canadian call areas.

Arriving home, we were greeted by a QSL from WA1YRB, my last QSO from Signal Hill, saying what a thrill it had been for him to work a station operating from the site of the original Marconi experiment. It was a thrill for us too—a real DXpedition to the past. ■

REVIEW

from page 28

are only a few hundred cycles away from the DX, what then?

Have no fear, the Varifliter will come to the rescue—but first you will have to hook it up. Just open the box that Kantronics has shipped it in, dump out a few thousand soft plastic packing "worms," retrieve the warranty card and instruction booklet, and somewhere down under all that is the Varifilter. It is packaged in a two-tone beige and brown cabinet measuring about 6 inches square and only 2½ inches high.

An ac line cord is neatly coiled up and waiting for you to plug it into a source of 115-volt alternating current. If, by any chance, you don't have (or prefer not to use) ac, Kantronics has made provisions for 12-volt dc input on the back panel by means of a 2.5-mm diameter "phone" plug. When you lift the Varifilter out of its nest, you immediately notice how light it is, and how good it will look on the operating desk or maybe even on the receiver itself, as in my shack. Now, let's see, where's that instruction book? Oh, here it is. It suggests that you connect the receiver's speaker output to an RCA-type phono jack on the rear panel and plug your external speaker into a 3.5-mm jack, also on the rear panel.

The book tells you that the input voltage protection circuitry in the Varifilter will protect its innards from damage due to momentary voltage spikes and excessive and negative voltages. It's comforting to know that it won't go BZZZZTTT and curl up its toes when you hook it up. If you prefer to use headphones instead of an external speaker, just plug them into the headphone jack (standard ¼-inch style) also located on the back panel.

Now it's time to look at the front of the unit and see what knobs and switches there are to be learned (and cussed at when you select the wrong one). What's this? Simplicity itself—only three round knobs, two rectangular push-buttons, and a couple of LEDs. The left-most knob says Volume, the middle one, Bandwidth, and the right-most knob, Frequency. The left-hand switch is power off (out)/ power on (in).

Ahhh... let's push that Power switch—the little left-hand LED rewards us with a ruby glow. So far, so good. We rotate the volume control to the right and immediately hear some CW signals coming through the Varifilter. Hmmm... wonder how they sound in the "straight through" mode? So, we push the on-off switch to off, and hear signals typical of our receiver: *lots* of signals.

Hoping that the Varifilter does, in fact, filter, I push it to *on* once more. By tweaking the frequency knob a bit, the right-hand LED begins to blink in time with an incoming signal centered in the passband. Just about right, maybe 900 Hz, or a bit less: comfortable copy. Now, I reach over to the Bandwidth knob and rotate it ever so slightly. The received signal immediately and drastically "sharpens" in the speaker. By golly, this little critter does work!

For the next hour or so I play around with the Frequency and Bandwidth controls, narrowing and widening the "window" through which we listen to the incoming signals. I find that the Frequency control is very critical when using the filter in its narrow bandwidth position, and care must be exercised to keep that little LED blinking in rhythm with the CW.

By carefully adjusting receiver tuning and the Varifilter, it's possible to achieve a remarkably comfortable and solid-copy signal through all kinds of QRM. Just to satisfy an urge to see what the receiver will do by itself, I switch the Varifilter off, and promptly lose the station I was getting Q5. Whoops... back "on" again, and there it is, still solid.

Time to see what the Peak mode switch does, so I pop it out and am rewarded with a very much enhanced signal strength —much louder than my receiver brings it to me under the same conditions. I do notice that the adjacent "hash" is also enhanced, but with a slight readjustment of the Bandwidth, the hash is gone. Wow! this is really making copy easy! And so it goes, day after day under poor band conditions, evening QRM, static, etc., etc., and I'm beginning to find out just how helpful this little Varifilter can be. After a while, I am scarcely aware it is in the circuit. Tuning across the band, I can dig out signals that I didn't know were copyable, signals that wouldn't have been readable without the Varifilter.

Ordinarily, I'm not a sideband operator and don't often use my rig in that mode. But, what the heck, the Varifilter is supposed to do its thing with SSB, too (and for that matter, ASCII, RTTY, etc.). Once again, I put the little box through its paces and found it equally adept at removing the typical sideband crud that obscures the wanted signals. Not surprisingly, the Varifilter works with little fuss, muss, and bother. It just sits there and blinks contentedly while churning out solid copy.

For those who are interested in such things, the technical facts are straightforward. The bandwidth is continuously variable from about 30 Hz to over 1000 Hz and, once set, remains constant regardless of frequency. The frequency is variable from less than 150 Hz to over 1000 Hz, thus accommodating almost any audio preference. Capable of 2 Watts audio output power, the Varifilter can drive the shack speaker or headphones to unbearable levels. Because of the variable nature of the filter, one can tune it on, above, or below the desired signal and vary the width of the audio bandpass to suit nearly any taste.

Modular design has been incorporated for serviceability and, should service ever be required, components can be removed and shipped to Kantronics for repair or replacement. Incidentally, if you wish to use the Varifilter on dc, you don't have to disconnect the ac line cord. If your shack is provided with 230 volts ac, don't despair. A tiny switch inside the Varifilter, reachable by screwdriver without removing the cover, allows you to set it for that voltage.

The instruction book is large, easy to read, clearly illustrated, and a joy to behold because it contains a nice schematic diagram and a parts list which shows the value and number of every part used. If you wish to service your Varifilter (after warranty is over), you shouldn't have any trouble, because Kantronics' instruction manual is about all you could wish for.

All in all, the Kantronics Varifilter is a most satisfacory device for the average ham and for the contester and DXer as well, making difficult copy quite easy and turning nearly impossible copy into Q5 reception. At only $139.95, the Varifilter is economically feasible and will make a worthwhile addition to any shack. I didn't try it on RTTY (or ASCII for that matter), but have no reason to suppose that it wouldn't PERFORM equally well on those modes. Try it, I think you'll like it! For further information, contact *Kantronics, 1202 E. 23rd Street, Lawrence KS 66044; (913)-842-7745.*

MFJ SHORTWAVE CONVERTER

Like many other hams, I have always enjoyed listening to the shortwave broadcast bands. The BBC, Voice of America, Deutsche Welle, Radio Moscow (in very small doses!), and countless others provide commercial-free programming of a very high quality. A lot of hams would like to spend more time listening, but they just can't seem to find the time. When it comes down to a choice between operating the ham station and listening to shortwave broadcasts, the ham station always wins!

A few years ago, I briefly considered getting a radio with shortwave capabilities for my car. What could be better than to catch up on a some shortwave listening while driving to work? I quickly dismissed the idea when I found out how much such a car radio costs. Only a few very expensive European models offer shortwave coverage, and I wasn't about to buy a radio that was worth more than the rest of the car!

Recently, MFJ began advertising two shortwave converters for the car. The MFJ 304 covers 19, 25, 31, and 49 meters in four bands, and the MFJ-308 covers all the above and adds 13, 16, 41, and 60 meters. This seemed too good to be true. I imagined that the sensitivity would be low and the selectivity would be poor,

but at $79.95 for the eight-band model, the little box was sorely tempting, and I banged off an order to MFJ Enterprises.

When the package came a couple of weeks later, I dropped everything, grabbed my toolbox and ran out to the car. Groping around under the dashboard in the middle of a New Hampshire winter isn't exactly a laugh a minute but, fortunately, installation only took about 15 minutes.

I unplugged the car's antenna lead from the radio, plugged it into the converter, and plugged the output of the converter into the antenna jack on the radio. The converter operates on 12 V dc, which is easy to get in my car; I just tap into the filtered line I have for two-meter equipment. That's all there is to it!

I am a compulsive manual reader, so I checked the manual before I went any further. I needn't have bothered; operation couldn't be simpler. The converter is normally in the off state. When you push in one of the band switches on the front panel, the converter is activated. Tuning is then accomplished normally with the tuning knob on your car's am radio. When you want to listen to stations on the local broadcast band, you merely push the off switch and the converter is switched out of the circuit completely.

With no further ceremony, I punched the bandswitch for a band known for its daytime activity, and started tuning around. I was absolutely astounded. The thing was amazing! Any fears I had about sensitivity were banished. As I tuned up and down the band I heard exceptionally strong signals everywhere, and the selectivity was excellent. I was so excited that I didn't know what to do with myself, and several other *73* staffers who came out to see what the commotion was all about were equally impressed. In the next twenty-four hours I found all sorts of excuses to go for a drive, and each time I was rewarded with the reception of several interesting programs from every corner of the globe. MFJ has a winner.

Problems? Yes, I had a couple of minor problems. The mounting brackets included with the converter are a bit on the small side and I'd rather see MFJ furnish the more typical U-shaped bracket. Admittedly, such a bracket would add to the cost of the unit, and since you aren't likely to be moving the converter around very often, the slight inconvenience of the present system is acceptable.

MFJ's shortwave converter.

The only other problem doesn't have anything to do with the converter itself, but can involve your car instead. If your car's ignition system isn't up to snuff, it can produce a tremendous amount of amplitude-modulated hash. If your present radio can hold its own against this ruckus, the converter will do fine, too, as long as you don't try to listen to extremely weak stations, which tend to get lost in ignition noise. If your car's ignition noise is well under control and your am radio has good sensitivity, you'll be able to DX to your heart's content.

Serious problems are conspicuous in their total absence. This unit performs so well that I am surprised that there aren't more such converters on the market. The entertainment and educational value of this little box from MFJ is fantastic. If you have any interest in shortwave listening, MFJ has an incredible value for you!

The MFJ World Explorer II is available from *MFJ Enterprises, Inc., PO Box 494, Mississippi State MS 39762.* Reader Service number 484.

BENJAMIN MICHAEL INDUSTRIES 24-HOUR CLOCK

What can one say about a clock, you ask? Plenty, if it's this quartz-crystal controlled twenty-four-hour clock from BMI.

How many times have you agonized over the conversion of local time to UTC? Well, maybe you're smarter than I am, but I always have a problem going from Eastern Standard or Eastern Daylight to UTC. I'll admit it is a bit simpler before noon, but in the *afternoon*, Ugh!

Enter Benjamin Michael Industries with their little liquid-crystal-display clock. It sits quietly on the table top, receiver, shelf, transmitter, windowsill, or wherever your imagination might suggest. BMI provides small mounting lugs on each side of the plastic case so that the clock can be mounted in a panel. It can be attached to any number of other things by means of those lugs—it's versatile, too!

A front-panel toggle switch and two push-buttons allow you to set the time as follows: flip the toggle to Set and cycle the hours and minutes with the Hours and Minutes push-buttons until the proper numbers come up in the window. As soon as WWV or CHU give their time-set tones, just flip the toggle back to the left and you're on time. Seconds are ticked off unobtrusively yet visibly by the blinking of the colon that separates hours and minutes. It is pleasant to finish a QSO and just look at the time expressed in hours amd minutes UTC—makes a log-keeping a snap!

The liquid-crystal display is set within a surrounding bezel which is mounted on an alodined or anodized (black) aluminum front panel. The 1.5-volt pen cell mounts in a clip on the bottom of the case. Inside is a glass-epoxy printed-circuit board which appears to be gold-plated for corrosion resistance. The back of the case incorporating the mounting "ears" is easily removed by two small screws set into the sides of the case, near the rear edges.

There is a slot at the bottom rear of the assembled unit which appears to be wide and long enough (¼" W × 2" long) to accommodate something like a ruler or yardstick. There is a tiny hole for a screw in the center of the back, suggesting that this little clock could be mounted at one end of a long, thin stick, like a yardstick. I'm not sure why anyone would want to do that, but it does seem possible, *if* you want to. Maybe it's for a pendulum; do you suppose...?

I have watched the little clock perform like a champ for two whole weeks, and know what? It hasn't lost or gained a millibleem, measured against WWV, in all that time.

For $24.95, how can you hate it? You can't! Get one, because you need it to keep from going bananas trying to figure out UTC. More information can be obtained by contacting *Benjamin Michael Industries, PO Box 173, Prospect Heights IL 60070.* Reader Service number 482.

MASTER HANDBOOK OF ELECTRONIC TABLES & FORMULAS
by Martin Clifford

In the introduction to this book, the author notes that there are a number of ways to solve problems in electronics. The first is to use formulas and to plug in or substitute numerical values. As the author states, "This technique calls for some arithmetic dexterity and, quite often, a good working knowledge of algebraic and trigonometric functions, and sometimes a bit of calculus. Aside from the work involved, the use of a formula has the disadvantage in that it supplies a single solution."

The second method of solving problems in electronics involves the use of nomographs which also can give a number of alternative solutions.

A third method is provided in this book by presenting electronics data in tabular form with minimal use of arithmetic. The answers to electronics problems are given immediately in the tables if the elements of the

problems are known.

The tables are based on standard formulas used in electronics and provide answers of a much higher order of accuracy than is commonly needed for the solution of electronics problems. The tables also provide a number of alternate solutions much as do nomographs, allowing the user a choice of practical component values that may be required in circuits.

Of interest to the amateur are tables giving solutions for resistance and conductance involving such things as equivalent resistance of two resistors in parallel, resistance vs. conductance, resistivities of conductors, and design values for three types of attenuator networks, T-pad, H-pad, and π-pad. There are tables on voltage and current, capacitance, inductance, impedance, permeability, power decibels, and sensitivity.

If, for example, you require a simple attenuator pad to supply an insertion loss of 40 dB, you can go to the table on Design Values for Attenuator Networks and, for a T-pad, locate 40 dB in the left-hand column of the table. Then, to the right of this value, read the values for R1 and R2, where R1 represents two resistors each having a value of 588.1 Ohms. R2 is shown as having a value of 12 Ohms. The same method can be used to locate desired resistance values for the H-pads and π-pads.

There is a chapter on antennas which I found of little use for the amateur. The standard publications for amateurs are much better sources of antenna information and it is my feeling that some other aspect of electronics could have been substituted for this short chapter on antennas.

For the amateur interested in computers, there is a chapter on digital logic and number conversion tables and a chapter on symbols, codes, and alphabets which includes the American Standard Code for Information Interchange (ASCII).

For the constructor, there are chapters on transistors covering alpha vs. beta and methods of testing transistors, wire, color codes, time constants, and both RC and RL constants.

As the author indicates in his introduction, there is a limit to the number of electronics tables that can be prepared. When a problem requires more than two component parts of the formula, it is better to use the formulas or nomographs than to try to set up tables.

As stated, this book's purpose is to save time and work, and on this basis I found this book useful and worth its $14.95 price. It is available from *Tab Books, Inc., Blue Ridge Summit PA 17214.*

HAM HELP

We are happy to provide Ham Help listings free, on a space-available basis. We are not happy when we have to take time away from other duties to decipher cryptic notes scrawled illegibly on dog-eared post cards and odd-sized scraps of paper. Please type or print (neatly!), double spaced, your request on an 8½" × 11" sheet of paper and use upper- and lowercase letters where appropriate. Also, please make a "1" look like a "1," not an "l," which could be an "el" or an "eye," and so on. Hard as it may be to believe, we are not familiar with every piece of equipment manufactured on Earth for the last 50 years! Thanks for your cooperation.

I have a Koyo Model JL-451 CCTV camera and need a photocopy of the owner's manual. Also, does anyone have a modification for improving the product detector in an HQ-110A VHF made by Hammarlund?

Finally I need an SSTV alignment tape. I will copy and return.

Ira Linderman WB2RXR
89 Dovecote Ln.
Commack NY 11725

Help! I need some assistance down here in South America.

First, I need help in getting the paperwork completed for my local amateur license. I am told that it would be much faster if I had another ham who knows the ropes to help. I have listened to the local repeater till I am somewhat blue, but no one ever gives out their phone number and of course I do not dare give a call, since the laws here are very strict about that.

Second, I am looking for a simple circuit which will help us in a Bible competition—a question and answer type of program. The requirements would be as follows:

One button per each team member. Three teams, 4-6 members per team. When a team member's button is pushed, it would lock out all other buttons, while lighting a light on the button block and an LED or digital readout for the team and team member on the console. A reset button on the console would also be needed.

Finally, I am looking for an IC that would work with a TT decoder project I am working on for my bench and for possible use with a portable repeater when I return to the United States in three and a half years. For the first prototype, I plan to use 567s since they are somewhat available here (even though very overpriced).

I am looking for a chip that would give me a numeric readout rather than one of a row of LEDs to signify the decoded digit. Being somewhat of a beginner, I am not sure which chip or IC would be a good choice.

At present, the 567 output is fed to a 7402 or one of three 7402s which in turn gives a high output depending on the digit decoded, i.e., 1-0, *, #. Thus, the feed or output to the needed IC would be any one of 12.

I would appreciate any help which readers could give on these matters. Thank you very much and may God bless you.

SOCIAL EVENTS

Listings in this column are provided free of charge on a space-available basis. The following information should be included in every announcement: sponsor, event, date, time, place, city, state, admission charge (if any), features, talk-in frequencies, and the name of whom to contact for further information. Announcements must be received two months prior to the month in which the event takes place. They should be sent directly to Editorial Offices, 73 Magazine, Pine Street, Peterborough NH 03458, Attn: Social Events.

OLD BRIDGE NJ
MAR 1

The Old Bridge Radio Association will hold its first annual auction of ham radio, electronic, and computer equipment on March 1, 1981, at the Cheesequake Firehouse, intersection of Rtes. 35 and 9, Old Bridge NJ. The exhibition will begin Sunday morning at 11:00 am, and the sale will begin at noon. Refreshments will be available. Talk-in on .72/.12 and .52. For more information, call Fred Goldberg at (201)-257-8753.

DAVENPORT IA
MAR 1

The Davenport Radio Amateur Club will hold its tenth annual hamfest on March 1, 1981, from 8:00 am to 4:00 pm at the Davenport Masonic Temple, Highway 61 (Brady Street) and 7th Street, Davenport IA. Tickets are $2.00 in advance, $3.00 at the door. Tables are $4.00 each with a $2.00 additional charge for an electrical hookup (limited number). Features will include over $2,000 worth of major prizes. Hotel discounts and refreshments will be available. There will be a pre-hamfest Saturday night banquet with Paul Graver, midwest ARRL SCM, as guest speaker. Banquet tickets are $8.00 and reservations must be paid by February 18, 1981. Talk-in on 146.28/.88, W0BXR. For advance tickets, dinner, and table reservations, write Dave Johannsen WB0FBP, 2131 Myrtle, Davenport IA 52804.

GRAND JUNCTION CO
MAR 7

The Grand Mesa Repeater Society will hold the second annual indoor Western Slope Swapfest on March 7, 1981, at the Lincoln Park Barn, 12th and Gunnison, Grand Junction CO. Doors will be open from 10:00 am through 4:00 pm and admission is free. Swapfest tables are $4.00 in advance. Attractions will include commercial exhibitors, a flea market, an auction, and prizes. Raffle tickets for the grand prize of a Tempo S-1 are $2.00 each. Talk-in on 146.22/.82. For further information, send an SASE to Larry Brooks WB0ECV, 3185 Bunting Avenue, Grand Junction CO 81501, or call (303)-434-5603.

STERLING IL
MAR 8

The Sterling-Rock Falls Amateur Radio Society will hold its 21st annual hamfest on Sunday, March 8, 1981, at the Sterling High School field house, 1608 4th Avenue, Sterling IL. Advance tickets are $2.00 and tickets at the door are $2.50. A large indoor flea market will be restricted to radio and electronic items only. Tables are available for $5.00 for commercial and $3.00 for others. Plenty of free parking will be available, including an area to accommodate campers and mobile trailers. Many prizes will be given away, including a first prize of a minicomputer. Doors open at 7:30 am. Featured will be a movie, "The World of Amateur Radio," to be shown throughout the day, bargains, good food, and plenty of close-by activities for XYLs and kids. Talk-in on .52 and WR9AER .25/.85. For advance tickets and tables, write Sue Peters KA9GNR, 511 8th Avenue, Sterling IL 61081. Make checks payable to Sterling-Rock Falls Amateur Radio Society and enclose an SASE.

MIDLAND TX
MAR 14-15

The Midland Amateur Radio club will hold its annual swapfest on Saturday, March 14, 1981, from 1:00 pm until 7:00 pm, and on Sunday, March 15, 1981, starting at 8:00 am, at the Midland County Exhibit Building east of Midland TX on Highway 80. There will be door prizes. Preregistration is $4.50 or $5.00 at the door. Talk-in on 146.16/146.76. For more information or to pre-register, write the Midland Amateur Radio Club, Box 4401, Midland TX 79704.

TRENTON NJ
MAR 15

The Delaware Valley Radio Association, W2ZQ, will hold its 9th annual flea market on Sunday, March 15, 1981, from 8:00 am to 4:00 pm at the New Jersey National Guard 112th Field Artillery Armory, Eggerts Crossing Road, in Lawrence Township, NJ. Advance registration is $2.00, $2.50 at the gate. There will be indoor and outdoor flea market areas. Sellers are asked to provide their own tables. Prizes and refreshments will be available. Talk-in on 146.07/.67 and 146.52. For additional information or tickets, write DVRA, PO Box 7024, West Trenton NJ 08628. Please include an SASE.

WINCHESTER IN
MAR 15

The Randolph Amateur Radio Association will hold its 2nd annual hamfest on Sunday, March 15, 1981, from 8:00 am to 5:00 pm, at the National Guard Armory, Winchester IN. Admission is $2.00 in advance or $3.00 at the door. Table space is $2.50 and table space with table (limited supply) is $5.00. Space reservations must be made in advance. Features include prizes, programs, new equipment displays, a flea market, and refreshments—all indoors with security. Talk-in on 147.90/.30, 223.30/224.90, and 146.52. For advance reservations and information, contact Jake Life W9VJX, Box 162, Winchester IN 47394, or phone (317)-584-9361.

CANTON OH
MAR 21

The Canton Amateur Radio Club will hold its annual auction on March 21, 1981, at the Nimishillen Grange Hall, Easton Street NE, Canton OH. The doors will open at 4:00 pm and the auction will start at 7:30 pm. An Icom IC-2A and an antenna tuner will be given away as door prizes. The two-meter check-in prize will be an Avanti antenna. Check-in on 146.19/.79. For advanced tickets and/or further information, send an SASE to R.A. Stellarini WB8VUN, 1003 Shadyside Avenue SW, Canton OH 44710, or phone (216)-453-5896 after 5:00 pm.

MARSHALL MI
MAR 21

The Southern Michigan Amateur Radio Society and the Calhoun County Repeater Association will sponsor the 20th annual "Michigan Crossroads" Hamfest on Saturday, March 21, 1981, at the Marshall High School, Marshall MI. Doors will open at 7:00 am for exhibitors and at 8:00 am for buyers and lookers. Free parking, unloading help, and food service will be available. There will be a special craft section for the ladies, and door prizes and talk-in prizes will be awarded. Table space is $.50 per foot and will be reserved until 9:00 am. Talk-in on .07/.67 and .52. For more information, write SMARS, PO Box 934, Battle Creek MI 49016, or call Earl Goodrich at (616)-781-3554.

SO. SIOUX CITY NE
MAR 21

The 3900 Club and the Sooland Repeater Association will sponsor Hamboree 5 on Saturday, March 21, 1981, at the Marina Inn, So. Sioux City NE. Doors will open at 9:00 am. Advance registration, including the banquet, is $10, tickets at the door are $12, and the Hamboree only (no dinner) is $2. Present will be Midwest Director Paul Graver W0FIR and *QST*'s Stuart Leland W1JEC, who will present two programs. Features include CW contests, a special Novice meeting, many programs throughout the day, commercial exhibitors, a flea market, old-time radio and amateur exhibits, and prize drawings. At 6:00 pm, there will be a banquet featuring Toastmaster John Daniels WA0GQK. There will be special programs for the ladies. Reservations for a 3 x 8 foot table are $2 and can be made by contacting Al Smith W0PEX, 3529 Douglas Street, Sioux City IA 51104. For advance tickets and motel reservations, write Jerry Smith W0DUN, Box 14, Akron IA 51001. For more information, contact Dick Pitner W0FZO or Glen Holder K0TFT.

CHARLOTTE NC
MAR 21-22

The Mecklenburg Amateur Radio Society, Inc., will sponsor The Charlotte Hamfest and ARRL North Carolina state convention on March 21-22, 1981, at the Civic Center, Charlotte NC. Close by are hotels, restaurants, and secure parking. Aisle booths are $60.00 and end

booths (in pairs) are $160.00. This includes a name sign, two tables, dividers, and electricity. For more information or booth reservations, write The 1981 Charlotte Hamfest, Mecklenburg Amateur Radio Society, Inc., 2425 Park Road, Room 023, Charlotte NC 28203, Attention: Bob Darke W4MHF. On Friday, March 20, 1981, the annual Charlotte Hamfest "Attitude Adjustment" party will be held in the Civic Center Hospitality Room.

IRVINGTON NJ
MAR 22

The Irvington Radio Amateur Club will hold its hamfest on Sunday, March 22, 1981, from 9:00 am to 4:00 pm at the P.A.L. Building, 285 Union Avenue, Irvington NJ. Take the Golden State Parkway to exit 143 north or 143A south. There will be refreshments available. Admission is $1.00 and tables are $3.00. Talk-in on .34/.94 and .52. For further information, call Pete WB2FAS (201)-763-8220, or write IRAC, P.A.L. Building, 285 Union Avenue, Irvington NJ 07111.

MAUMEE OH
MAR 22

The Toledo Mobile Radio Association, Inc., will hold its 26th annual auction and hamfest on Sunday, March 22, 1981, at the Lucas County Recreation Center, Key Street, Maumee OH. Hours are from 8:00 am to 5:00 pm. The free auction starts at 10:00 am. There will be ample free parking all day and overnight. Tickets are $2.00 in advance and $3.00 at the door. Flea market tables are available; displays are limited to electronics and ham gear. There will be commercial exhibits, refreshments, door prizes, and a big raffle—all inside. Prizes include a Kenwood TS-130 with power supply, two Icom IC-2AT HTs, a Bird Wattmeter, and many more. There will be an additional ladies' program. Bring your YL, XYL, or OM and make a day of it. Talk-in on 146.52/.52. Area repeaters are 146.01/.61, 146.19/.79, 146.34/.94, 147.87/.27, and 147.975/.375. For additional information, write J. Honisko N8BGH, 1733 Parkway Drive N., Maumee OH 43537.

COLUMBUS GA
MAR 28-29

The Columbus Amateur Radio Club will hold its hamfest on March 28-29, 1981, at the Columbus Municipal Auditorium. Admission is free. A ticket donation is $1.00, and inside swap tables are $5.00 per day. There will be a free outside flea market. This is an ARRL hamfest and will include an ARES forum. Talk-in on .28/.88. For table reservations, contact K4RHU, 2701 Peabody Avenue, Columbus GA 31904, or phone (404)-322-7001. For more information or tickets, contact N4ATI, 263 Logan Avenue, Ft. Benning GA 31905, or phone (404)-687-3272.

PHILADELPHIA PA
MAR 29

Penn Wireless Association, Inc., will hold its Tradefest '81 on Sunday, March 29, 1981, at the National Guard Armory, Southhampton road and Roosevelt Boulevard (Rte. 1), ½ mile south of exit 28 on the Pennsylvania Turnpike, Philadelphia PA. General admission is $3.00 and a 6' x 8' seller's space is $5.00 with an additional $3.00 for a power connection (limited number). Each sales space will entitle the seller to one free admission. Doors will open at 7:00 am for setup and at 8:00 am for general admission. Features will include prizes, refreshments, displays, rest areas, and surprises. Talk-in on 146.115/.715 and .52. For more information, contact Kenneth Marinoff K3FKW, PO Box 734, Langhorne PA 19047.

MADISON OH
MAR 29

The Lake County Amateur Radio Association will hold its 3rd annual Lake County Hamfest on Sunday, March 29, 1981, at the Madison High School, Madison OH. Admission is $2.50 in advance (send an SASE before March 14, 1981) and $3.50 at the gate. Display space, including table(s) if desired, is 85¢ per linear foot. Table rent with reservation will hold a space until 10:00 am. Highlights will include commercial exhibits for ham and computerist, an inside flea market, a computer raffle with a prize of an Ohio Scientific C1P Series 2 personal computer with monitor, cassette, and 8K RAM. Also, door prize drawings will be held hourly, with first prize being a Ten-Tec Delta 580 with 280PS. Plenty of overnight accommodations are available within a 15-minute drive. Talk-in on 147.81/.21. Check-in on 146.52/.52. For further details, write Lake County Hamfest Committee, 5555 Anaconda Road, Mentor OH 44060, or call (215)-953-9784.

BRAINTREE MA
MAR 29

To celebrate its 50th anniversary in amateur radio, the South Shore Amateur Radio Club will hold an indoor flea market on Sunday, March 29, 1981, at the Viking Club, 410 Quincy Avenue, Braintree MA, from 11:00 am to 4:00 pm. The entrance fee of $1.00 includes one chance for the door prizes. Additional chances may be purchased at 3 for $1.00. There will be eight-foot tables available for $7.50 each (which includes one free admission). Vendors will be able to set up at 10:00 am. Plenty of free parking will be available. For advance table reservations, send a check, payable to the South Shore Amateur Radio Club, to Ed Doherty W1MPT, 236 Wildwood Avenue, Braintree MA 02184

ROCHESTER MN
APR 4

The Rochester Amateur Radio Club and the Rochester Repeater Society will sponsor the Rochester Area Hamfest on Saturday, April 4, 1981, at a new location, John Adams Junior High, 1525 NW 31 Street, Rochester MN. Doors will open at 8:30 am. There will be a large indoor flea market for radio and electronics items, prize raffles, refreshments, and plenty of free parking. Talk-in on 146.22/.82 (WRØAFT). For further information, contact RARC, WBØYEE, 2253 Nordic Ct. NW, Rochester MN 55901.

UPPER SADDLE RIVER NJ
APR 4

The Chestnut Ridge Radio Club will hold a ham radio and computer flea market on April 4, 1981, from 9:00 am to 3:00 pm at the Education Building, Saddle River Reformed Church, East Saddle River Road at Weiss Road, Upper Saddle River NJ. Tables will be available for $10; tailgating, $5. There is no admission fee. Food and drink will be available. For further information, contact Jack Meagher W2EHD, (201)-768-8360, or Neil Abitabilo WA2EZN, (201)-767-3575.

GOTEBORG SWEDEN
APR 4-5

The Goteborg Transmitting Amateurs invite all interested hams to an international ham meeting in the Swedish Trade Fair Centre, Goteborg, Sweden, on April 4-5, 1981. Featured will be a thematic stamp exhibition; lectures on VHF, UHF, and SHF; and meetings for YLs, award-hunters, and DXers. Other programs to be announced are fox-hunting, a mobile-radio contest, and a CW speed contest. A hamfest will be held on Saturday night.

PADUCAH KY
APR 5

The Paducah ARES Club will hold its 2nd annual ham/swapfest on Sunday, April 5, 1981, from 8:00 am to 5:00 pm, at the National Guard Armory, Paducah KY. There will be hourly as well as grand prize drawings. Dealers will be on hand. Talk-in on 147.66/.06 and 146.52. For additional information, contact Larry Reid AI4T, Chairman, 220 Longview Drive, Paducah KY 42001.

FRAMINGHAM MA
APR 12

The Framingham Amateur Radio Association will hold its annual Spring flea market on Sunday, April 12, 1981, at the Framingham Police Station drill shed, Framingham MA. Doors will open at 9:00 am and admission is $1.00. Sellers' tables are $7.00 in advance and $8.00 at the door. Talk-in on .75/.15 and .52. For more information or seller pre-registration, contact Ron Egalka K1YHM, 3 Driscoll Drive, Framingham MA 01701, or phone (617)-877-4520.

AMBOY IL
APR 26

The Rock River Amateur Radio Club will hold its 15th annual hamfest on April 26, 1981, at the Lee County 4H Center in Amboy IL, one mile east of the junction of Rtes. 52 and 30, 10 miles south of Dixon IL. There will be free coffee and donuts starting at 8:00 am. Camping space will be available at a nominal charge. Six-foot display tables are $5.00 each and tickets are $1.50 in advance, $2.00 at the gate. Talk-in on .37/.97 and .52. For full details, contact Charles (Chuck) Randall W9LDU, 1414 Ann Avenue, Dixon IL 61021, or phone (815)-284-6380.

LETTERS

from page 20

and more people interested in hamming not only for a possible career but just a "good life." You pursued a career with ham radio. I, the "good life" as an executive in a large corporation!

J. F. Irwin W6ECB
San Francisco CA

ONE MAN'S OPINION

With regard to Wayne's editorial in the December, 1980, issue, it is reasonable to assert that the use of calculus and lots of mathematical equations is not essential to the pursuit of radio technology by amateurs or technicians, and to be guided by this conviction is tailoring the articles which you publish. It is unreasonable to take the same editorial opportunity to condemn college calculus in general as you seem to have done. The danger in such condemnation is its possible influence on impressionable younger readers who admire you for your many accomplishments and thus tend to attach undue importance to what is really just one man's opinion.

Many of these youngsters are faced with important career decisions and will latch on to any guidance they can find. Some are contemplating enrollment in university courses of science or engineering, courses for which calculus is a requirement despite your low opinion of its merit. These people should be advised that opinions differ widely on the role of mathematics in the sciences, and that yours is representative of just one extreme. Everywhere in the ham community can be found dedicated, intelligent, and successful people who are diametrically opposed to the views you express.

Calculus is the mathematics of motion and change. As such, it plays a vital role in the exposition and understanding of physical principles, indeed, so much so that it has become part of the very language in which many sciences are couched. Thus, the student must know a fair amount of calculus to cope with the science texts that he is required to master, or to comprehend the lectures which are an essential part of his science education. To disdain the calculus is to disdain communication with some of the greatest minds of past and present. Most working scientists employ both mathematical and physical reasoning in their work, emphasizing one or the other, depending on their personal tastes and talents. When the going really gets tough, they are happy to try any tool available.

Please bear in mind that nearly a half century has elapsed since Wayne's own, unfortunate encounter with college math. Many drastic changes have occured both in the way the material is presented and in the extent to which students must acquire proficiency in it if they are to get the most from their subsequent courses in the sciences.

In 1940 only a relatively few Americans went on from high school to colleges and only a small fraction of college students enrolled in calculus. Today the subject is taught in many high schools, and probably a lot of the brighter students who opt for the course are themselves part of the very ham fraternity that you are so eager to serve.

In time, these students will acquire proficiency not only in calculus, but in disciplines such as linear analysis and matrix algebra whose practical importance has been amplified by the emergence of electronic computers, and whose practical need has been amplified by things like the increased attention which engineers are devoting to systems theory.

So please try to be more tolerant. When someone submits an article containing a few equations, don't just dismiss it as a display of ego or pedantry. Perhaps the author was just trying to express himself in the way which seemed clearest to him. Can you be so sure that you are an infallible guide as to how it would be clearest to others? No manner of presentation has a monopoly on clarity or success.

Larry Potts W2FOH
Williamsville NY

SAFETY FIRST

I am very far behind in my reading. However, I would still like to comment on the article in the August, 1980, *73* by WB6MXD for constructing the Gel/Cell charger ("A Different Kind of Charger," p. 115).

I would like to point out that any device powered from the 120 V ac power line or even from a battery capable of delivering large amounts of current should never be built without being appropriately fused.

To be safe, this charger should have a fuse not exceeding ½ Amp in the 120 V ac primary circuit, and to be totally safe should also have a fuse not exceeding 1 Amp in the ac secondary circuit.

Most everyone would be amazed at how fast wire insulation can burst into flames when current flow is not restricted. If a diode shorts in a rectifier bridge, this can easily occur.

Rodger Williams N0BRG
Minneapolis MN

CARROT DANGLING

I'd like to comment on Wayne's idea of a code-free (theory-free?) ham license. We already have one! It's called the Novice License. The code and theory required for Novice are so simple that anyone who can read can get a ticket. Even some bright gradeschoolers are licensed.

Most people who don't know about code or electronics are afraid to learn anything about ham radio. Learning code and theory is work. Work should have a reward. The CW-only Novice license is not enough reward for people who are accustomed to voice communication. It's hard to convince a CBer or teenager to learn code, theory, and laws for a radiotelegraph ham license. This is especially so when he finds out he must learn more code, more theory, and more laws, and then have to travel to a distant city for the exam for a radiotelephone ham license.

Almost everyone has had a prospective ham become discouraged to find out that the Novice ticket you're offering to help with will allow only CW contacts and, worse still, that the equipment for the four bands *is* expensive. For the prospective Novice to invest that much work and money is a big decision. I feel that more would make that decision if phone privileges were included in the reward. Not a lot of privileges, but just enough for a carrot.

For example, a new phone subband at 28.4 to 28.5 with a 250-Watt limit. Novices could meet with all other classes of hams on this band, get encouragement, ask questions, and gain experience. I'll bet that more interesting CW contacts would come from Novices who are exposed to a little phone fun. I'll also bet more Novices would be licensed because of phone privileges.

So, how about an easy-code (easy-theory?) license with a carrot to entice the newcomer?

Larry W. Garens WD8CIY/5
Brady TX

QRZ HAWAII

The McKinley High School Amateur Radio Station (KH6NF) is trying to make contact with teenagers and young adults around the world. McKinley High School is the oldest public high school in the state of Hawaii, being 115 years old this school year. We are located in Honolulu, just minutes away from the famous Diamond Head crater and Waikiki Beach. Our student population is just over 2000 students and would rival the United Nations with our diversity of culture and national heritage.

The club station has been in operation since 1966, but this year we are making a special effort to contact other club stations and younger members of the amateur radio society. We are inviting everyone to join us on the bands and make this year an outstanding one for the youth in amateur radio.

Our hours of operation will be from 1730Z to 1815Z and 0045Z to 0130Z Monday through Friday, and 2000Z to 2130Z Monday, Wednesday, and Friday. At present, we operate on 28.530 MHz ± QRM. If 10 meters closes up, we will operate 21.320 MHz or 14.320 MHz. We also operate in the Novice band on 21.195 ± QRM.

If you are unable to contact us because of poor band conditions, please drop a line to set up a schedule and we will do our best to have a QSQ with you.

McKinley High School
Amateur Radio Station
1039 S. King Street
Honolulu HI 96814

SAVE LIVES

Thanks for encouraging repeater owners to install emergency locator transmitter (ELT) monitors. Such monitors definitely assist search and rescue (SAR) forces in two important ways. First, in many areas of the *country no one* monitors 121.5 MHz so repeaters can often be the first to report a distress signal. Second, the moderate height of most repeaters (when compared to a search aircraft or a ground-level search team) provides valuable information in reducing a search area to a manageable size.

Others in the amateur community also can assist in SAR. Homebuilders, designers, and commercial firms can work on creating inexpensive but selective and sensitive 121.5- and 243.0-MHz direction finders and receivers. Commercial firms might also market DFs in kit form to keep costs down. Traffic handlers can offer their services to local SAR teams. Transmitter hunters with equipment for 121.5 or 243.0 are always welcome. All of these areas make good club projects as well. The resulting favorable publicity certainly would help the club and amateur radio in general.

Amateurs interested in this work should get in touch with the SAR organization in their area. If they know someone in their local Mountain Rescue Team or Civil Air Patrol unit, then that's a good place to start. If not, they can write to HQ CAP–USAF, Maxwell AFB, AL 36112, for the address of their state's CAP Wing. I can also provide this information if they wish.

I hope that many more amateurs will find, as I have, that saving lives can be more rewarding than just saving QSLs.

McGuire Air Force Base NJ 08641

ELITISTS

Must we be subjected to such unthinking and irresponsible drivel as KB7HM proposes (*73*, December, 1980), namely the elimination of theory *from* the licensing exams? It has already been tried in the CB service, and look at the mess that has resulted! Do we want this on the ham bands as well? Is learning such a painful process?

To examine the question from another angle, what benefits, if any, do we achieve as a result of theory requirements in the exams? "That," as Mr. Shakespeare said, "is the question."

Hams may well look with pride at their many contributions to the science of radio communications and many associated arts. I submit that much of this progress has come about because the technical requirements that KB7HM would eliminate are accepted as demonstration that the individual knows enough of what it is all about so that the freedom to innovate, to experiment, can safely be entrusted to him or her, as the case may be. As an example, while I cannot buy a ten-meter linear, there is no problem with my making and using one. It is this freedom which has made ham radio what it is, in contrast to the electronic anarchy that we find on eleven meters.

If we were to abandon requirements to have at least a glimmer of what makes the wheels go 'round, the future of ham radio might as well be turned over to the equipment manufacturers, who would certainly lick their figurative chops at the prospect of hordes of new (and ignorant) customers to buy their goodies.

If ham radio is not to degenerate into another CB mess, where a fistful of bucks is the only requirement, technical know-how must remain an important factor in licensing, and ham radio will again be capable of providing many technically oriented men and women for industry, or for national emergency, as in the past.

Elitist group? You're damn right! We hams have over the years earned the right to that title! Those who find it too difficult, too painful, or just don't want to be bothered to learn will always find a Bash to pander to their wants. To each his own! But let's not throw the baby out with the bath water!

Henry S. Keen W5TRS
Fox AR

PROFESSIONAL RADIO

Wayne's answer to the letter concerning radio-theory testing requirements for amateur radio licensing (*73*, December, 1980) was "Let's hear it for the code-free, theory-free license." Such an attitude concerns me greatly.

I do agree with him in principal that code or theory really should not be a requirement, for as one will note, it is called "amateur" radio as opposed to "professional" radio. However, without the requirements we would be in serious trouble. Personally, I had a great deal of trouble passing the theory test (flunked it the first time), I am not capable of designing or repairing (unless very simple) my own equipment, I do not use the code that almost cost me my sanity to learn, yet I am a firm believer in those testing requirements.

I feel this way *not* because I think they make you a better radio operator, not because I think you should be able to fix your own gear (I envy those that can), nor because I think everyone should be a finger-talker, but because it is the only way I know of to date to keep amateur radio from becoming an expanded citizen-band radio.

I will be the first to admit that all the time I spent learning code and theory was a waste of time for I retained none of it; then, again, I feel the same way about the language requirement for my PhD—truly a waste of time, the only French I know today is *oui* (and that is because there is a magazine with that name). I feel that even though I did not choose electronics as my field, and at the same time have no desire to use CW, I do have a right to use the radio as does everyone. In addition, however, I feel that along with that right comes responsibility that must be taken seriously if I am to use this privilege.

Ten years ago I was also into CB. At that time I would say "This is KFK-1988 looking for __," and everyone used callsigns and proper radio procedure. There were a few who didn't take it seriously but we ignored them or asked that they use proper procedure. Slowly, their numbers increased until those of us that used our callsigns were in the minority and considered somewhat weird by the average CBer.

I cannot accept today's CB procedures nor do I want to search the deep abyss of my brain to come up with the world's greatest handle (and let's face it: The most important thing to a good CBer is the handle). Consequently, I have a box full of CB gear in my basement that has not felt a volt of electricity for ten years. Personally, I feel that perhaps they too have a right to the airwaves and if they choose to use a handle instead of a callsign, I can choose not to participate. In addition, it provides a place for the serious radio operator and the not-so-serious operator, each able to use the radio for their enjoyment—everyone has a choice.

Presently, the theory and code requirements are the only mechanisms that keep in check (with pretty good results) the professionalism of this amateur hobby. I know of no test that will scrutinize potential radio operators that would guarantee polite, professional, courteous, careful radio operators, and I recognize that the present system also allows a jackass to occasionally slip by the system.

I sympathize with those potentially fine radio operators that cannot pass that tests and therefore cannot give us the pleasure of their company on the bands. I can only say to keep trying, for we'll be waiting. However, if the FCC does away with the testing requirements, you and I both know what will happen and you and I will also be making a choice between selling our equipment or finding that super-unique handle (how about "Hambone"—seems appropriate).

So, until someone comes up with something better, let's not open the floodgates to the unprofessional, careless, unscrupulous, rude individuals who will turn a hobby that presently brings enjoyment into one which will bring frustrations and ulcers to us all. Amateur radio is still a hobby that generates friendships throughout the country, is considered a privilege, and approached professionally and seriously by 99.9% of its license holders—let's not jeopardize

(down-right lose) it by taking off all testing requirements until a better system is designed which will retain the high caliber it is today. What good would a license to operate be (even if very simple to acquire) if you wouldn't want to use it after you did obtain it?

Timothy W. Joseph WB0MIS
Plainfield IL

SHELL GAME

I hope you will print this letter and that your readers will be as burned as I am. It all started when I read David Sumner's (K1ZZ) "It Seems to Us" article in the December, 1980, *QST*. The more I read the more I felt I was participating in a fast-talking carnival shell game. You know, the old "now you see it—now you don't."

I read the K1ZZ article and the small print tucked away on page 51 of the September, 1980, *QST* five or six times before I got the whole picture. Judging from the letters in the Correspondence section of the December issue, complaining about the 25 kHz on the 40-meter band, many people completely missed the point. The rap occurred on the 20-meter band, but I will get to that later.

K1ZZ almost had me in tears of gratitude with the Board's concern for the ham's plight when the MUF drops below 14 MHz. But he explained that the new 10-MHz band gained at WARC would be the solution to that problem. Oh, joy!

Then he tells me that the Board recommended that this band (that was to be my salvation when the MUF dropped) be used only for CW and RTTY. Egad! What will the majority of the operating hams get out of this band? Nothing! The ARRL has ballyhooed us for months about the new band they gained for us at WARC (now you see it), then they turn right around and recommend restricting its use to CW and RTTY only (now you don't). All that talk about the MUF dropping below 14 MHz was just something to distract attention from the real issue, which is, how they are going to go about slicing the frequency pie.

But that's not all the Board did. The old shell game is just warming up. Since the CW and RTTY boys were handed the best band that was gained at WARC something must be done for the phone operators, right? Wrong!

Well, in all honesty, something was done for approximately 6% of the licensed hams, the Extra class operators. The Board recommended opening up the 7.075-7.100-MHz portion of the 40-meter band and the 14.150-14.200-MHz portion of the 20-meter band to the Extra class guys.

K1ZZ's article was strangely silent in regard to the 50 kHz on 20 meters that was handed over to the Extra class operators. Nor did his article mention that it was this 50 kHz that troubled the Board the most in deciding upon what to recommend. Who took care of the Extra class guys? According to my 1979 *Callbook*, the Board members are:

Name	License
Dannals	Extra
Anderson	Extra
Bieberman*	Extra
Butler	Extra
Carpenter	Advanced
Grauer	Extra
Holladay	Extra
Miller	Extra
Nathanson	Extra
Oubre	Extra
Stevens	Extra
Sullivan	Advanced
Thurston	General
Wangler	General
Wicker	Advanced
Zak	Advanced
Powell*	Canadian

*These board members voted against the resolution.

As you can see, 10 of the 17 board members are Extra class licensees, and they voted to take care of themselves. Don't be unduly grateful to Bieberman (W3KT) for his opposing vote. Apparently he opposed the resolution because his recommendation on how to slice the pie failed. Incidentally, his recommendation opposed giving the General and Advanced class operators the paltry 25 kHz on 20 meters that they did get.

The only board member deserving of any respect is Powell (VE3OT). At least he voted in the best interest of the hams he was representing. We all know it would be in his best interest to keep stateside calls out of the band below 14.2 MHz.

OK, it's time to give you the score, the net effect of the Board's recommendation. If you tried to decipher this from *QST* you would need a magnifying glass and a flowchart to know the outcome. Here are the results complete with the winners and losers.

For Generals, Advanced, and Extras, RTTY and CW will be OK on 10.100-10.150 MHz, a gain of 50 kHz.

Extras only: 7.075-7.100 MHz (25 kHz) and 14.150-14.200 MHz (50 kHz).

Advanced ops in the 14.175-14.200-MHz range get 25 kHz.

Generals: 14.225-14.250 MHz (25 kHz).

The only real winners are the Extra class operators. They gained an additional 75 kHz on phone. I can't argue with the fellow who studies and passes the Extra class exam and as a result gets rewarded with extra privileges. But in this case, the Extras did nothing to earn the 75 kHz. For the same effort, the Generals and Advanced class licensees got only 25 kHz. The 25 kHz are an insult to one's pride and intelligence. It's like pitching a steak bone to a dog.

Based upon the license class statistics in my 1979 *Callbook*, the losers (Generals and Advanced) represent about 51 percent of the licensed hams. I wonder how long the ARRL would survive if it retained only its 6% favored membership?

No doubt about it: The CW operators are losers also. They swapped 75 kHz on 20 and 40 meters for 50 kHz on a band where they don't have any equipment or antennas.

Another big loser is the Advanced class DXer. If you don't believe me, just check your log and notice how many of the really rare countries you bagged on the bottom 25 kHz of 20 meters. The crowded conditions will again push the rare DX to the lower end of 20 which will be out of the Advanced class operators' reach.

I suppose what bothers me most is that I feel like I have been had. The Board feels free to dictate and to manipulate its own ARRL members. They expect me to swallow K1ZZ's snow job. They think they can force the CW operators to move, too, and to open up the new 10-MHz band for them. They think they can force hams to upgrade to Extra by penalizing them 50 kHz. They expect people like me to keep their mouths shut. Well, I've got news for them. I'll upgrade when I get damn good and ready to do so—and I will not keep my mouth shut.

Robert G. Ray WB4TCH
Germantown IN

Picky, picky, picky. —Wayne.

REMEMBERING WHEN

In the December, 1980, issue of *73 Magazine*, I was fanning through in preparation to reading it when two names jumped out at me, MacKinlay Kantor and Bandel Linn. I had the good fortune to meet both in Sarasota back in 1954 and 1955 when I worked for Kent McCinley (*The Sarasota News*). Kent asked me to come down and set up a darkroom and photographic staff and Bandel was doing the cartoons for the *News*.

The first time I met him was a bitter cold morning. The City Editor wanted a shot of the official thermometer over on Midnite Key and I had to go by Bandel's and get him out of the sack because the Editor wanted a snowbird drawn sitting on top

of the louvered cabinet that housed the official thermometer. Bandel's first words were "I dunno what the hell a snowbird looks like."

I met MacKinlay Kantor the first time at the post office where I had been sent to get a shot of him mailing the manuscript to the publisher on a Monday morning. It was later the next year that he won the Pulitzer Prize for that manuscript, *Andersonville*. We became good friends and I used to drop in at his place every time I was over at the beach on an assignment.

We talked about Spain a great deal as I had at one time rented a house in a little village and thought I could loaf for a whole year. But after a month and a half, I was going nuts so I had the agent sub-lease it and I came back to the states.

My tenant was Mac Kantor. We used to get a big laugh out of it. He told Johnny, who owned the Beach Club, that I was a hell of a landlord and wouldn't fix the pipes, but where else could he rent a six-room house on the beach. A house that housed Hemingway, Michener, and myself. Where else could he find a house with all that room and two servants all for fifty dollars a month, and keep a dog, Lobo.

One of the most touching obits I have ever heard was the one Mac wrote when Lobo died. Mac loved that dog.

I met a number of interesting people at Mac's home: Ben Stahl, the artist, had a beautiful home on the key and I did a spread for *House Beautiful* on it. He bulldozed a hill and built the house with a basement—unheard of in Florida those days. There was a *john* in the basement! When you closed the door, a panel on the right-hand wall slid up and a bar with a small refrigerator below was at your elbow.

Another person I met at Mac's was a folk singer with a guitar—Burl Ives.

I left Sarasota and moved to Miami where I lived until I had to have my leg amputated (bad circulation) and then moved to Riverview, a small town south of Brandon which is a small town south of Tampa.

RTTY LOOP

from page 18

tional cassette recorder. The unfortunate side is that no compatible tape system is used for these tapes. So, owners of large 6800 systems cannot assemble programs on the large system, dump them to tape and load that tape into the ATR-6800. They are forced either to figure out some direct way of loading or to type in programs by hand, which is very tedious for long programs.

So, let's see what we have. The Microlog ATR-6800 is a versatile computer-based (Motorola 6800) RTTY/Morse system capable of operating on Baudot, ASCII, or Morse. Enhancement programs are available to add convenience functions in the standard modes, or to add additional modes, namely, transmission of SSTV (reception is not supported). Used on Baudot RTTY, probably the most likely application, the unit can provide good solid communication, once familiarity with the unit is obtained. Other modes can be run with ease equal to Baudot, and operation is similar, no matter what the mode.

Problems? Well, putting the functions on the keycaps would help the learning process immensely. Tuning is marginal with the provided indicator; two LEDs for Mark and Space would make tuning less of a chore. The display size is a function of the amount of RAM dedicated to the video display; nonetheless, forty characters on RTTY is a bit more than half of a standard RTTY line, and any attempt at formatting is useless. A hard-copy printer is probably still needed for any type of message or novelty work; this may be one of the new ASCII printers, however, and need not be an old green-key-greaser. The character generator could be changed to a more standard type, and perhaps another software function provided to switch the keyboard into conventional lowercase unshifted, uppercase shifted format in ASCII.

Fig. 2. ATR-6800 keyboard commands.

Overall, it's a good unit, but I don't think it is the end of the line. Microlog is actively working on new options and features, as are many other manufacturers. I think we all need to keep our eyes open—it can only get better.

We will catch up on some reader input next month, and take a look at more equipment useful to the RTTYer as time goes by. Questions about RTTY? Even if we covered it a few years ago, you may have missed it. Let me know what you need to find out, and look for the answer here in RTTY Loop.

HAM HELP

I recently obtained a Trio 9R59D general-coverage communications receiver, but no schematic or service manual was available from the previous owner. I will gladly pay for photocopies or an original manual. This receiver was manufactured in the 60s and sold by Simpsons-Sears in Canada. Thank you.

F. G. Clark Forrest VE3BOF
102 Richmond St. N.
Hensall, Ontario
Canada N0M 1X0

I need two things. First, a schematic for a Knight C-577 speech compressor. Second, a schematic/manual for a signal monitor, Model SM7403, made by Defense Electronics, Inc., of Rockville MD. Most important, I need to know what i-f frequency the signal monitor operates with. Without that, I cannot use it!

Any costs for schematics/manuals or copies thereof will be happily reimbursed. Please notify me of what you have.

CONTESTS

from page 14

BARTG SPRING RTTY CONTEST

0200 GMT March 21 to
0200 GMT March 23

The total contest period is 48 hours but not more than 30 hours of operation is permitted. Time spent as listening counts as operating time. The 18 hours of non-operating time can be taken at any time during the contest but off-periods may not be less than 3 hours at a time. Times on the air must be summarized on the summary sheet. There are separate categories for single-operators, multi-operator, and shortwave listener stations. Use all amateur bands from 80 through 10 meters. Stations may not be contacted more than once on any one band.

EXCHANGE:

The message exchange consists of 1) time in GMT; this must consist of a full four-figure group and the use of the expression "same" or "same as yours" will not be acceptable. 2) RST and message number; the message must consist of a three-figure group starting with 001 for the first contact made.

SCORING:

All two-way RTTY contacts with other stations within one's own country earn two points; those contacts outside your country are worth ten points. All stations can claim a bonus of 200 points for each country worked, including their own. Note that any one country may be counted again if worked on a different band, but continents are counted once only. The ARRL country list is used and, in addition, each W/K, VE/VO, and VK call area will be counted as a separate country. Final score is sum of QSO points times the total number of countries worked added to the number of countries times 200 bonus points each times the number of continents. Note, proof of contact will be required in cases where the station worked does not appear in any other contest log received or the station worked does not submit a check log.

AWARDS:

Certificates will be awarded to the leading stations in each of the three classes, the top station in each continent, and to the top station in each W/K, VE/VO, and VK area. If a contestant manages to contact 25 or more different countries on two-way RTTY during the contest, a claim may be made for the Quarter Century Award (QCA) issued by BARTG and for which a charge of $3.00 (USA) or 15 IRCs is made. Make your claim at the same time you send in your log. Holders of existing QCA awards will automatically have new countries added to their records. However, due to the high volume of work, it will not be possible to prepare and dispatch any new awards or update any existing awards until the final results of the contest have been evaluated and published.

Additionally, if any contestant manages to contact stations on two-way RTTY with each of the six continents and BARTG Contest Manager has received either a contest or check log from each of the six stations concerned, a claim may be made for the WAC Award issued by the American *RTTY Journal.* The necessary information will be sent to the *Journal,* which will issue the WAC Award free of charge.

ENTRIES:

Use a separate sheet for each band and indicate all times on the air. Logs should contain: date/time in GMT, callsign of station worked, RST and message number sent, time, RST and number received, and points claimed. Logs received from shortwave listeners *must* contain both the full report sent and received by the station logged. Incomplete loggings are not eligible for scoring. The summary sheet should show the full scoring, the times on the air, and in the case of multi-operator stations, the names and callsigns of all operators involved with the operation of the station. All logs must be received by May 31, 1981, in order to qualify. Summary and log sheets are available from the Contest Manager at the address shown below. The judges' decision will be final and no correspondence can be entered into, in respect of incorrect or late entries, and all logs submitted will remain the property of the British Amateur Radio Teleprinter Group. Send entries to: Ted Double G8CDW, 89 Linden Gardens, Enfield, Middlesex England EN1 4DX.

TENNESSEE QSO PARTY

2100 GMT March 21 to
0500 GMT March 22
1400 to 2200 GMT March 22

This is the 11th annual QSO party sponsored by the Tennessee Council of ARC. You may work the same station on different bands, modes, or counties. Repeater contacts are not allowed. Mobiles compete against mobiles, portables against portables. Single-transmitter entries only, please. No county-line operations allowed for multiple contacts. Portable stations must set up per Field Day rules. No "list" operations are allowed.

EXCHANGE:

Signal report and state, province, country, or TN county.

SCORING:

Score one point per phone QSO; two points per CW QSO on 80, 1.5 points on other bands. Combine phone and CW score as one contest. TN stations multiply QSO points by sum of number of different states, TN counties, and VE/VO provinces. All others multiply QSO points by the number of different TN counties worked. For stations working outside their home TN county, score 200 bonus points for each county with a minimum of 10 QSOs. A power bonus multiplier of 1.5 is available to all stations operating at 200 Watts dc or less during the entire contest period.

FREQUENCIES:

Phone—3980, 7280, 14280, 21380, 28580.

CW—approx. 50 kHz up from bottom of each band, Novices within their bands.

AWARDS:

Plaque to TN winner, TN mobile, and portable, plus out-of-state winners. Certificates with complete contest summary to every station sending in logs with at least 15 contacts.

ENTRIES:

Logs must show date/time in GMT, station worked, band, mode, exchange, and score. Use separate log sheets for each band with over 50 contacts. Submit a cross-check sheet similar to ARRL CD77 if over 200 QSOs are made. Logs must be legible to avoid disqualification. Logs must be mailed by May 1, 1981, to: Dave Goggio W4OGG, 1419 Favell Dr., Memphis TN 38116. Please include a business-sized SASE with your logs.

CARF PHONE COMMONWEALTH CONTEST

1200 GMT March 21 to
1200 GMT March 22

This contest is sponsored by the Canadian Amateur Radio Federation (CARF) and is open to all radio amateurs licensed to operate within the Commonwealth or British Mandated Territories. Operators may use the entire 24-hour contest period. All contacts must be made on SSB using 80 through 10 meters. Only one contact may be made with any station using a Commonwealth callsign except those within the entrant's own call area. UK stations may not work each other for points.

EXCHANGE:

RS report and a three-figure serial number commencing with 001 and increasing by one for each successive contact in the contest period, irrespective of the band in use. Each exchange must be acknowledged by the receiving station.

FREQUENCIES:

Suggested frequencies are a plus or minus 20 kHz of 3600, 3780, 7080, 14180, 21200, 28480.

SCORING:

Each completed contact scores five points. Additionally, a bonus score of 20 points may be claimed for the first, second, and third contacts with each Commonwealth call area on each band. All UK stations count as one call area.

ENTRIES:

Entries may be single- or multiband. Single-band entries should show contacts on one band only; details of contacts made on other bands should be enclosed separately for checking purposes. Only single-operator entries will be accepted. A single-operator station is

one manned by an individual who received no assistance whatsoever during the contest period. Multiband entries will not be eligible for single-band awards. Points are deducted for errors in the logs. For unmarked duplicate contacts for which points have been claimed, additional penalty points may be deducted. Each entry will consist of the separate band logs, including call area check lists, a summary sheet, and dupe check sheets. Each entry must also be accompanied by a signed declaration that the spirit and rules of the contest were observed, as well as the terms of the contestant's license. Entries should be addressed to: CARF Contests and Awards Committee, PO Box 2172, Station D, Ottawa, Ontario, K1P 5W4 Canada. Under no circumstances should entries be sent via RSGB. The closing date for entries is June 1, 1981.

SPRING VHF QSO PARTY

1800 GMT March 28 to 0400 GMT March 30

Sponsored by the Ramapo Mountain ARC. The contest rules are the same as for the ARRL VHF QSO Parties except FM operation is not permitted below 450 MHz.

EXCHANGE:

Signal report and ARRL section.

SCORING:

One QSO point for 50- to 144-MHz contacts, 2 points for 220- to 430-MHz contacts, and 3 points for 1215 MHz and up. Multiply QSO points by the sum of ARRL sections per band.

ENTRIES:

Use the ARRL VHF QSO Party or similar forms, or send an SASE to RMARC for entry forms. All who submit entries will receive a copy of the results. Mail entries by April 27, 1981, to: Ramapo Mountain ARC, PO Box 364, Oakland NJ 07436.

YL ISSB QSO PARTY—CW

0001 GMT March 28 to 2359 GMT March 29

Two six-hour rest periods are required. Operating categories include: single-operator, DX/WK teams, and YL/OM teams. All bands will be used and the same station may be contacted on different bands for contact points but not as country multipliers. All contacts, however, must be made outside the American phone bands. Two meters may be used, but contacts must be direct and not through repeaters.

EXCHANGE:

Name, RST, SSB'er number, country, state, and partner's call. If no partner, leave blank. If non-member, send "no number."

FREQUENCIES:

3665, 7070, 14070, 21070.

SCORING:

Score eight points for each member contacted on any continent. Non-member contacts count one point. Only member station contacts count for multipliers. Multipliers are each state, country, and province, also, each team contacted, but only once for each team. When DX/WK partners contact each other, it counts as a double multiplier. Final score is sum of QSO points times the total multiplier.

AWARDS:

Extraordinary certificates will be issued to the highest individual score, DX/WK teams, YL/OM teams, and score for highest single-operator category. Regular certificates to the highest state, country, and Canadian province winners.

ENTRIES:

Logs must show date/time (GMT), RST, SSB'er number, partner's call, mode of operation, band, and period of rest time. Summary sheets show number of states, Canadian provinces, countries, YL/OM teams, DX/WK teams, and partner contacts. All entries must be postmarked by May 15, 1981.

Any member desiring to enter the DX/WK Team category should immediately send request to Lyle F. Shaw KC4LF, 6329 Fairway Blvd., Apollo Beach FL 33570. For record purposes, requests should be made in writing. In the week preceding the QSO party, members desiring a partner may request one through system controls on SSB'ers daily systems. No team assignments will be made after the party begins.

YL/OM teams are self-evident in their operation and need not file. Single-operator category members are eligible unless entered with teams. Non-members enter single op only! DX/WK teams consists of a DX and WK member. The team score is the sum of both partners. Score to be determined when both logs are received. When only one log is received, credit will be given as a single-operator. YL/OM teams consist of one YL member and one OM member who are related: husband/wife, father/daughter, mother/son, and brother/sister. Operation must be from the same QTH, using the rig with his/her own call.

WORLD RTTY CHAMPIONSHIP

The IATG Radiocommmunications and CD publications are again sponsoring a series of contests for RTTYers on all continents. The purpose of the contest is not only to increase interest among radio amateurs for RTTY, but also to promote interest in long-range contacts. That is, to stress intercontinental contacts rather than domestic contacts as in previous contests. For this purpose, IATG and CD have organized three contests during the year. The first was back in January but information was received too late for publication. The remaining contests are the North and South American RTTY Flash Contest this month and the Europe and Africa RTTY Giant Flash Contest in May.

For each of the three contests there will be a general winner plus a winner from each of the two continents involved. Separate standings for each continent plus a general standing for each contest, will be published in various magazines. Points for the overall championship will be awarded as follows:

For contest winners—First place, 50 points; Second, 46 points; Third, 43 points; Fourth, 41 points; Etc. to 44th, 1 point.

For continental winners—First place, 25 points; Second, 22 points; Third, 20 points; Fourth, 18 points; Fifth, 17 points; Etc. to 21st, 1 point.

Standings are independent, continental winners can also be general winners.

At the end of the three contests, continental and general standing points will be totaled and a World Champion of the Five Continents will be declared according to the new final standing obtained. Prizes as usual are awarded for the four first-place winners. Consolation prizes will also be awarded.

NORTH AND SOUTH AMERICA RTTY FLASH

1800 GMT March 28 to 0200 GMT March 29
1200 to 2400 GMT March 29

The points and multipliers are awarded in a manner to encourage long-range contacts, which are an indication of the operator's ability and the efficiency of his equipment. The contest committee is open for suggestions or constructive criticism which will be considered for the rules for future contests. They are especially interested in suggestions as to what regulation they might incorporate in future contests to encourage the use of home-made microprocessor and/or programming on commercially available equipment in RTTY. Use all bands from 80 to 10 meters. Operating classes include single- and multi-operator with single transmitter plus SWLs. Each station may be contacted only once on any one band. Remember that all contacts must be on RTTY!

EXCHANGE;

RST, QSO number, and your continent.

SCORING:

QSO points are earned as follows: QSO on 80 or 40 meters—2 points; 20—3 points; 15—6 points; 10—8 points. No points or multipliers for contacts with one's own country. Only two-way RTTY contacts are valid.

Multipliers are given for countries and continents. Use the DXCC country list, plus count each call area of VE/VO, W/K, VK, PY, LU, JA, and UAØ/9 as separate countries. A multiplier is given for each country worked on the 20 through 10 meters. *No* multipliers for contacts on 80 or 40 meters with one's own continent. A separate multiplier may be claimed for the same country if a different band is used (maximum of 3 times). Only countries which appear in at least 3 other logs will be valid multipliers, unless a QSL confirmation is submitted. One's own country is not valid as a multiplier. For contacts with North and South America, both the sender and the receiver will receive 100 points as a multiplier. Each of the remaining continents receive 50 points. An additional 100 points will be given for each contact with North and South America on 15 or 10 meters.

The final score is the total QSO points times the total number of countries times the total number of continents plus the total points for NA and SA stations worked. Example: 600 QSO points times 10 countries worked times 100 continent points equals 600,000, plus 20 stations of NA and SA worked on 15-10 meters gives a grand total of 602,000 points.

Attention! Two promotional periods are included in the contest: 1900 to 2000 GMT March 28 and 1200 to 1400 GMT March 29. Stations operating from Europe, Africa, Australia-Oceania, and Asia contacting NA and SA during these hours will *double* their points for these periods.

Beginner handicaps are offered to RTTYers entering logs in the contest who have not participated in previous contests. They will receive an additional 5% of their final score. Additional handicaps offered are 10% of the total final score of the winner of previous RTTY Championships or 8% of the total final score for the winner of one or more preceding RTTY contests. SWLs also may enter and they should use the same scoring rules. A separate results table will be made for these entries.

AWARDS:

Prizes, as usual, are reserved for the four first-place winners. Consolation prizes will also be awarded.

ENTRIES:

Use separate log sheets for each band. Logs must contain date/time in GMT, callsign, RST and QSO number sent/received, country and continent multipliers, points, and final score. The contest disqualification criteria used by the ARRL in its contests apply also to this contest. Failure to observe any rules will result in exclusion of the entry for the final results and any such log will be considered as a check log. Logs compiling errors exceding 10% of the final score will also be excluded from the final standing. Each log received becomes the property of the IATG Radiocommunications and will not be returned. The decision of the organizing committee in any dispute will be final and any subsequent controversy may not be referred to the civil court. Remember that the contest is valid towards the final standing of the 5-Continent World Championship.

In order to qualify, all logs must be received no later than April 30, 1981. Send logs to: Prof. Franco Fanti, Via A. Dallolio n 19, Bologna 40139 Italy.

AWARDS

from page 22

managers of this new service? Meet Laryl Myers N7BMY who is the General Manager. She is relatively new to amateur radio but is already a dedicated brass-pounder— when she finds time. She has an extensive background in filing system management. It took Laryl only two weeks to learn the code and theory for her Technician license and then another two weeks after her ticket arrived to upgrade to General. She has definite goals of attaining 60 wpm on CW and indicates she will be an Extra someday soon! Jokingly, Laryl expresses regret that she doesn't expect to be on the phone bands for some time to come.

As for her counterpart, Laryl's assistant manager is Pat Berry KB7JW. Pat was first licensed in 1962 as K7SGX. He is strictly a CW operator who takes pride in working high-speed rag-chews, So far, his longest QSO has been 24½ hours continuous, but he hopes someday to top that time. Low end of 80 meters, anyone?

How do you use the service? It's all relatively simple. Keep at least two, preferably three, legal sized SASEs on file with the service at all times. Make sure they contain the current amount of first-class postage. Place your callsign in large block letters in the upper left-hand corner and in the middle of the flap on the back of your SASE. When you receive one of your SASEs, send another one to replace it. Don't forget your outgoing QSLs that you owe people. The service needs them to stuff waiting envelopes of the people you've had a QSO with.

To send cards into the outgoing bureau, pre-sort them in alphabetical order by call area. Place no more than 20 in each envelope, along with your 25¢ handling fee. Make sure you place proper postage on your envelope as the service cannot accept postage-due material. Address your cards to: US QSL Service, PO Box 814, Mulino OR 97042.

SIX-METER CROSSBAND AWARD

Sponsored by the Society for the Preservation and Encouragement of Six Meters, this new Crossband Award is awarded in acknowledgement of attaining two or more DX contacts made via six-to-ten meters crossband.

For those not familiar with crossband operation, this particular procedure becomes necessary for a good many European operators whose countries do not allow six-meter transmission due to commercial broadcasting frequencies being subjected to interference. To satisfy both the government needs as well as the wants and wishes of many European six-meter enthusiasts, a crossband effort has proven to be extremely effective and ever increasingly popular.

To apply for this award or to obtain more information about this society, write Armin Montavon WB9ØVC, SPESM Secretary, PO Box 268, S. Elgin IL 60177. The cost of the award is $1.00 to cover the postage and handling.

For those award seekers interested in specialized communications, let's review a couple of video awards being offered for SSTV and ATV respectively.

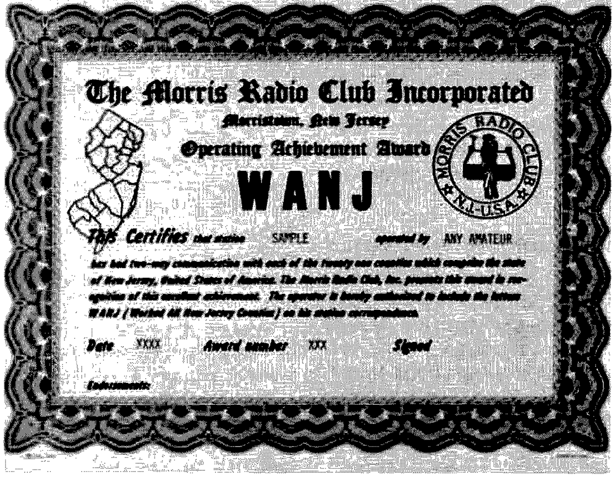
10-METER SSTV NET AWARD

There is a very successful SSTV-Video Net taking place each Saturday at 1800 GMT on 28.680 MHz. An average of 30 stations have been checking in with various interests in SSTV transmissions. To those who make 3 SSTV Net Check-ins, a very special Net Award certificate will be issued. For more details, why not check into the net or write one of the founders of the net? Contact Mike Stone WBØQCD, PO Box H, Lowden IA 52255.

ATV MASTER SCANNERS AWARD

Henry Ruh WB9WWM, publisher of *ATV Magazine*, has written and provided me with details of their Master Scanner Award. The award has various levels of operating achievement: work 5 stations on each of 5 bands, 6 stations on each of 6 bands, 7 stations on each of 7 bands, 8 stations on each of 8 bands, 9 stations on each of 9 bands, and 10 stations on each of 10 bands, or work 25 stations on 10 meters, 10 stations on 6 meters, or 10 stations on any band above 144 MHz.

Only contacts made after August 1, 1978, count toward this award. Submit your verified list of contacts with a $1.00



award fee to Master Scanner Award, PO Box 1347, Bloomington IN 47402.

WORKED ALL NEW JERSEY AWARD

The original Worked All New Jersey Award certificate is again being offered by the Morris Radio Club to all amateurs having established contact with all 21 New Jersey counties. There are no specific modes or bands required but endorsements will be granted for single band or mode accomplishments.

To apply, have your list of 21 counties verified by at least two amateurs or a radio club secretary. Forward this list along with an award fee of $2.00 to: Morris Radio Club, PO Box 53, Whippany NJ 07981.

100 CCXX AWARD

To the many (220-MHz) operators who read this column, the *220 NOTES* of the metropolitan Chicago area have an awards program designed expressly for you.

An attractive certificate is awarded to amateur radio operators who contact a minimum of 100 separate stations anywhere on the 220-MHz band, through a repeater or simplex.

To apply, prepare your list of contacts in order of date and time (GMT) worked. Have this list verified by at least two amateurs or a radio club secretary. Forward this application along with an award fee of $1.00 to: *220 NOTES*, Greg Pietrucha WB9SNZ, 2216 N. Kildare Avenue, Chicago IL 60639.

THE LITTLE BAY AWARD

This seems to be the month for amateur radio clubs. We hope other organizations will take the hint and submit their own awards as the L'Anse Creuse Amateur Radio Club has done. Here we announce their Little Bay Award.

Applicants need to confirm contact with 10 individual members from the radio club. DX stations require only 3 member contacts. A list of members and actual frequencies they monitor may be obtained by writing Ted Bak WB8ZME, 35751 Dunston, Sterling Heights MI 48077.

Once you have established the required contacts and obtained confirmation, submit your list to Ted along with an award fee of $1.00 to cover postage and handling.

WORKED ALL VERMONT AWARD

The Central Vermont Amateur Radio Club wishes to announce that it has once again reactivated the Worked All Vermont Operator Award.

To qualify for this award program, applicants must work 13 of the 14 counties of the state of Vermont. Applicants may utilize any band or mode or any combination thereof, with the exception of repeater operation. There are no time limitations.

To apply, prepare a list of qualifying contacts and have it verified by at least two amateurs or by a local radio club official. Send this list with an award fee of $2.00 to: Central Vermont Amateur Radio Club, c/o Grant Taylor, RFD #1, Box 150, Cabot VT 05647.

FCC

from page 32

would be able to make the call lawfully because then two amateur radio stations would be involved. No such convoluted rationale underlies the provisions of § 97.79(d). On its face, § 97.79(d) gives discretion to an amateur operator to allow a non-licensed person (i.e. a third party) to engage in communications using his transmitter, under proper monitoring conditions and supervision by the licensee. We concur with the staff's view that this refers to two-way communications. To say that this would preclude the licensed operator himself, as control operator, from using his own station to make a phonepatch strains credulity and we reject the inference that petitioner draws from its hypothetical situation.

10. Appealing on an equity basis, petitioner avers that under our interpretation of the rule, model aircraft enthusiasts who are not yet licensed amateur operators will be deprived of exposure to amateur radio activity because they are not permitted to control the aircraft by operating the amateur radio transmitter. We reject this argument for the reason that the person who truly has an avid interest in amateur radio has a myriad number of opportunities to advance his interest and to acquire proficiency in the art and hobby of amateur radio. In fact, it is quite probable that the model airplane enthusiast's major interest is in model airplanes, not radio.

11. We believe that any need for more channels for control of model aircraft should be met in the Radio Control Radio Service. In this connection, it is noted that AMA has a petition for rulemaking (RM-3248) currently on file with the Commission which asks for such additional frequencies.

12. In summary, we believe that it would be contrary to the public interest to permit a person who is not a licensed amateur radio operator to operate an amateur radio station to control a model aircraft. For all of the foregoing reasons, the interpretation of § 97.79(d) made by the Commission's staff is hereby affirmed.

Federal Communications Commission.
William J. Tricarico,
Secretary.

HAM HELP

I would like to obtain information on connecting an FSK/AFSK unit to use with a Macrotronics M-80 (M-800) ham Interface (TRS-80) in conjunction with a Kenwood TS-520. Any type of information is appreciated. All inquiries will be answered!!

James Gonsalves, Sr.
2257 Manhattan Place
Santa Clara CA 95051

I need the current address of Omega-T Systems, or a repair facility for the Omega-T antenna noise bridge, Model TE-01. The company is no longer receiving mail at 516 W. Belt Line Rd., Richardson TX. My bridge generates noise but will not null, even into a dummy load.

Bill Koczon W2HWQ

Brick Town NJ 08723

W2NSD/1 NEVER SAY DIE

editorial by Wayne Green

from page 8

als to work with, only the organization to make use of them is lacking.

The obvious thing then is to make a trip to Africa, sit down with the leaders of these countries and make them aware of the fantastic resource they have at hand and are not using. Unfortunately, the obvious is not always the best approach... and I guess that holds particularly with the Third World nations.

The weakness of the idea lies in the leaders, who are for the most part occupied largely with staying leaders. Just as the first item of business for an elected official in the US is to get started with his reelection campaign, the bulk of the effort for an African leader is in staying alive and in control. It is a fight for most of them and as a result they are far too busy to really consider matters of benefit to their countries.

Remember, if you will, my writing about the fear that most African governments have of personal communications. A leader who is having to fight daily to stay in power is going to have very little interest in the introduction of low-cost, portable personal communications. He'll rightly think that this will be an invitation for his foes and for terrorists to set up their communications for the purpose of doing him in. This is why the ARRL miniature transistor rigs were so completely rejected. Not that that has been much of a problem, for as far as I know most of these rigs have been either stolen or "mislaid" right here in the US and the whole project a disaster which the ARRL would prefer to cover up.

Visiting hams do not present any perceived danger to these African governments, so our DXpeditions are able to visit and operate from many of these countries. But when it comes to organizing anything in the way of communications for their citizens, that's another matter. The fact is that one is hard put to point to any African nation which appears stable at this time. I've visited a number of them and am getting letters from hams in others, so I'm keeping on top of the situation fairly well. You may be sure that if I see a good opportunity to visit a country with the expectation that I might succeed in getting amateur radio set up, I will be on the next jet.

In the meanwhile, we should be laying the groundwork for this. It *is* important that some representative of amateur radio reach the heads of the African countries and explain about amateur radio. While little may be possible right now, the stage can be set for something later on. The time just might come when the leader of a country is well enough established so he will have the luxury of starting some long-range plans to benefit his country. I hope we are there at that time...with our homework done.

THINKING OF WRITING?

While our top priority for articles is on state-of-the-art construction projects, the fact is that virtually every one of you has at least one good article bottled up in you, just waiting to get into print.

What do *you* enjoy reading about? Well, most other readers are just the same as you...so give some serious thought to having at a typewriter and getting into print.

If you're doing any kind of original designing and construction, be sure that you document every step so that you can help others to enjoy what you've done. Sure, you'll get paid for the article...and you'll hear about it from just about everyone you contact on the air or at clubs. Authors achieve a sort of instant stardom which is remembered for an amazingly long time.

If you're not into building, perhaps you've done some other things which would be of interest...a DXpedition...or even some interesting perspective on everyday hamming. When is the last time you read something interesting about traffic handling? About repeaters? DXing? Or even some idea which might help rag chewers...and heaven knows rag chewers need help more than any other group.

Have you been running some Novice classes and thus have some ideas which might help us get more hams? Or has your club come up with a project which might spark others into similar cooperative projects? Perhaps you know a ham who has done an outstanding job of helping others, organizing a net, or other work which would be of interest and inspiration to all of us?

How do you write? Simple... use a typewriter, double space, leaving generous margins for editing, send in hand-drawn sketches of circuits and the best photos you can manage. *73* pays for all material accepted for publication, unlike other magazines which either do not pay at all...or else may pay upon publication, which can be months later. Many hams, whose names you see often in print, are making their hobby pay very well for them...and in addition are getting the satisfaction of providing pleasure and inspiration for about 150,000 *73 Magazine* readers.

(Send for "How To Write For *73*"—just drop a card to Editorial Offices, *73 Magazine*, at the address below.)

As an author, you certainly want to get the top dollar for your work, not just give it away. You also want it to be read by the widest possible readership. This means you should get it to *73* for publication. Our technical staff will look it over and get back to you within several weeks and let you know if it has been accepted (along with a check). Or they may ask for some changes or additions... or even reject it. You still have three more ham magazine which are hungry for articles, so your chances of not being published at all are remote.

73, which publishes the most articles of all the ham magazines...and which reaches the active and enthusiastic hams ...is your best bet. Is that boast of publishing the most articles just smoke or is it fact? You can count 'em yourself. During 1980, *73 Magazine* published 290 feature articles. In the same time period, *QST*, the next largest ham magazine, published 142 articles...less than half as many.

Send your article to Jeff DeTray, *73 Magazine*, Peterborough NH 03458.

FUN!

Glendale NY 11385

What are hams *really* like? Have you, like many of us, ever pondered this question? What is it that draws people into amateur radio rather than, say, stamp collecting?

This month, we're setting aside the usual crossword, acrostic, matching, and other puzzles, and replacing them with something different. Something, we hope, that will be just as enjoyable as any puzzle to complete. What follows is a poll—a survey—that will tell us something about ourselves, who we are and why we do what we do.

This is not a scientific survey. For it to be such, we would have to solicit responses from a carefully selected cross section of hams. Instead, what we hope to gather are the random responses of readers of this column. A collection of the gut feelings of amateurs as they answer questions ranging from their personal life-styles to how they view emerging trends in our hobby.

So, please take the time to fill out the responses and mail them back to the address at the top of this column. If you don't want to cut up the magazine, photocopies are fine. You will note that there is no place on the form for your name, address, or call—this is an anonymous survey and we really don't want to know who you are, just what you think! In a few months, we'll be printing and analyzing the responses, and the results should be, to say the least, interesting. Have FUN!

ELEMENT 1—BACKGROUND

1) Sex:
   - A) Male
   - B) Female

2) Age:
   - A) 15 or below
   - B) 16-21
   - C) 22-39
   - D) 40-59
   - E) 60 and above

3) License class:
   - A) Novice
   - B) Technician
   - C) General
   - D) Advanced
   - E) Extra

4) Number of years licensed:
   - A) 1 year or less
   - B) 1-5 years
   - C) 6-10 years
   - D) 11-20 years
   - E) 21 years and up

5) Do you have a new (post-March '78) call?
   - A) Yes
   - B) No

6) How many hours a week do you devote to amateur radio?
   - A) 0-1 hour
   - B) 2-5 hours
   - C) 6-10 hours
   - D) 11-20 hours
   - E) 21 or more hours

7) Which HF band do you use most?
   - A) 80-75 meters
   - B) 40 meters
   - C) 20 meters
   - D) 15 and/or 10 meters
   - E) Don't operate HF

8) Which VHF-UHF band do you use most?
   - A) 6 meters
   - B) 2 meters
   - C) 220 MHz
   - D) 420 MHz and/or up
   - E) Don't operate VHF-UHF

9) Which mode do you use most?
   - A) SSB
   - B) CW
   - C) FM
   - D) AM
   - E) Other

10) How much money have you spent on amateur radio within the past year? (Include QSL expenses, magazine subscriptions, club dues, and other incidental expenditures.)
   - A) 0-$250
   - B) $251-$500
   - C) $501-$1,000
   - D) $1,001-$2,500
   - E) $2,501 and up

ELEMENT 2—SOCIAL CHARACTERISTICS

11) Has amateur radio influenced your career choice?
   - A) Greatly
   - B) Somewhat
   - C) Not at all

RESPONSE FORM

Instructions: Read each question and mark your response by circling the appropriate letter next to the number of the question. Please note that some questions have up to five possible responses, while others have as few as two. Please make only one circle next to each question number or, like the FCC, we will not count the entire question. Attach a separate sheet for any comments you might have.

Element 1:

1) A B
2) A B C D E

50) A B

12) If a Novice sent you a QSL after a QSO with no return package, would you answer it?
A) Yes
B) No
13) Do you routinely look up the license class of the person you're talking to in the *Callbook*?
A) Yes
B) No
14) Do you think amateur radio was better 10 years ago?
A) Much better
B) Somewhat better
C) The same
D) Somewhat worse
E) Much worse
15) Do you think amateur radio was better 20 years ago?
A) Much better
B) Somewhat better
C) The same
D) Somewhat worse
E) Much worse
16) Did you ever use a "cheat book" to upgrade your license?
A) Yes
B) No
17) If someone offered you a million dollars, tax free, on the condition that you give up amateur radio forever, would you?
A) Yes
B) No
18) Has ham radio ever interfered in your personal relationships? (I.e., time with your wife, husband, children, lover, etc.).
A) Yes
B) No
19) Have you ever tried to interest a family member in amateur radio?
A) Yes
B) No
20) Do you think most hams have a sense of humor?
A) Yes
B) No
21) Do you get upset when you hear hams "kidding around" on the air?
A) Yes
B) No
22) Have you ever intentionally jammed a repeater or otherwise purposely interfered with a QSO?
A) Yes
B) No
23) Do you think amateur radio lowers your neighbor's opinion of you?
A) Yes
B) No
24) If your closest ham friend beat you in a major contest, how would you feel?
A) He must be a better operator than me
B) Contesting is just luck
C) The contest was set up unfairly
D) It was easy for him to win, he has better equipment
E) He must have cheated
25) Do you make most of your friends through amateur radio?
A) Yes
B) No
26) When attending a ham club meeting, flea market, or convention, do you wear a callsign badge?
A) Yes
B) No
27) If you answered yes to the above question, what size is your badge?
A) 1 line
B) 2 lines
C) 3 lines
D) 4 lines
E) Larger
28) If your closest friend won a Collins KWM-380 in a contest, would you feel jealous?
A) Yes B) No

ELEMENT 3—OPERATING HABITS

29) Do you depend on a Morse code reader or microcomputer code display for most of your CW QSOs?
A) Yes
B) No
30) What sort of CW sending devices do you use most?
A) Straight key
B) Regular keyer
C) Memory keyer
D) Keyboard
E) Never send CW
31) If required, could you solidly copy CW at the speed at which you were licensed?
A) Yes
B) No
32) Have you ever purposely operated in an amateur subband you weren't licensed to use?
A) Yes
B) No
33) Do you think the FCC affects amateur radio in a positive manner?
A) Yes
B) No
34) What do you think of the new ham exams? (Answer this even if you have never personally taken one of these new tests.)
A) Excellent
B) Good
C) Fair
D) Poor
E) Terrible
35) Just for the heck of it, have you ever talked to a friend on the "wrong" sideband? (e.g., LSB on 20 meters.)
A) Yes
B) No
36) Do you ever speak to foreign, non-English-speaking hams, in their own language?
A) Always
B) Sometimes
C) I attempt it
D) Rarely
E) Never
37) Do you think "gentlemen's agreements" have any value?
A) Always
B) Sometimes
C) Never
38) Do you feel you are competent to replace the finals in a tube-type rig?
A) Yes
B) No
39) Do you feel you are competent to replace the finals in a transistor-type rig?
A) Yes
B) No
40) Have you ever built an electronic project from a kit?
A) Yes
B) No
41) Have you ever home-brewed an electronic project from a book or magazine?
A) Yes
B) No
42) Have you ever designed your own electronic project?
A) Yes
B) No
43) After meeting a ham radio acquaintance in person for the first time, do you usually think:
A) He is better looking than you thought
B) He is worse looking than you thought
C) He is about what you expected
44) On the whole, compared to the general public, do you think:
A) Hams are much better looking
B) Hams are somewhat better looking
C) Hams are average looking
D) Hams are somewhat worse looking
E) Hams are much worse looking

45) Have you ever operated a specialized mode? (i.e., RTTY, slow scan, etc.)
A) Yes
B) No

46) What do you think of contesting?
A) Great
B) Good
C) Okay
D) Don't like it
E) Despise it

47) What do you think of DXing?
A) Great
B) Good
C) Okay
D) Don't like it
E) Despise it

48) What do you think of repeaters?
A) Great
B) Good
C) Okay
D) Don't like them
E) Despise them

49) What do you think of traffic handling?
A) Great
B) Good
C) Okay
D) Don't like it
E) Despise it

50) Do you ever secretly hope that a mild disaster will strike your community just so you could display your amateur radio skills?
A) Yes
B) No

CORRECTIONS

There are two errors in "The Sweet Sounding Probe" (July, 1980, p. 84). First, output capacitor C6 is drawn with its polarity reversed. Second, there should be a connection indicated at the four-way crossover point of pin 8 of the 555, the left-hand lead of R6, the +12 V line from the regulator, and the line which eventually leads to pin D.

Howard Batie W7BBX
12002 Cheviot Drive
Herndon VA 22070

Readers interested in contacting the author of "Super Duper for Field Day" (November, 1980), p. 114, should use my new address and call. I have moved and there is little hope of any correspondence being forwarded.

David Hein WB8CEB
3004 Bandolino Lane
Plano TX 75075

In "Tracker—The Ultimate OSCAR Finder," January, 1981, pp. 88–95, there are some errors which have caused a bit of aggravation.

The address and telephone number of author WD8DRK, which appear near the start of the program listing on page 92, are incorrect. The correct address is given at the beginning of the article. Bruce's new phone number is (313)-835-0169. The trucking company which has been receiving his calls will appreciate your using the new number.

Lines 492 and 1830 should be deleted from the program; they are not needed.

Line 452 should be changed to read:

```
452 S$=CHR$(162)+CHR$(166)
```

The GOTO 7520 command at the end of line 1505 should be changed to GOTO 1520.

In line 1860, the left-hand bracket should actually be an up-arrow, indicating exponentiation.

Line 3190 should be changed and lines 3192 and 3194 added as follows:

```
3190 IF S=0 THEN S$="00"
3192 IF S<10 THEN S$="0"+RIGHT$(S$,1)
3194 IF S>=10 THEN S$=RIGHT$(S$,2)
```

Finally, the PET version of "Tracker" is no longer available from the authors. A version for the Apple II being planned, but it is not yet available.

Jeff DeTray WB8BTH
Assistant Publisher/Editor

It should be noted that in my article, "CB to 10—part XXIX: put that Hy-Gain CB board to use" (September, 1980, p. 102), if a 40-channel switch is used, then a jumper must be installed at the points on the board indicated by "J104."

All of my boards had it installed, although I have seen boards without them. I guess Hy-Gain had some units using different switches, or the trunk-mounted versions with interface cards that didn't require the jumper.

Many hams have written me about problems getting the trunk-mounted version running. As I cautioned in the article, you also need the mike and interface board. These parts, as described in my article, connect up to the standard circuit board in place of the channel switch (and other controls) to create the trunk-mounted version. There are, however, some nonstandard PC cards which can only be made into the fancy Hy-Gain 16 trunk-mount, microprocessor-controlled rig.

The mike on this rig looks like a calculator, with its keypad and small LED readout. The big difference is that the mike talks to the rig via a serial data line which is decoded by a special IC in the PLL chip location on the board. The main circuit board can be identified easily since it has an 18-pin MM58141N IC in place of the usual 16-pin PLL chip. Because of the serial data connection, the PLL cannot be converted as described in my article unless someone is willing to do a lot of digital design work with the microphone—definitely not worth the effort on a $10 circuit board.

I have talked to the people at Meshna, and they are willing to ship the convertible standard board (current price $8 for the board or $10 for the trunk-mount chassis) to anyone specifying that it is for conversion as in my article. This is a bit of extra work for them as they have to sort through the pile to find a standard unit. People should address requests to John Meshna, *Jr.*, PO Box 62, E. Lynn MA 01904.

available, over-the-counter, from electronic and personal computer component stores throughout the United States and Canada. Highlighted are microcomputer interface boards, Vector Plugbords™, motherboards, cases, tools, wiring terminals, and kits. A complete price list is included. *Vector Electronic Company, Inc., 12460 Gladstone Avenue, Sylmar CA 91342; (213)-365-9661.* Reader Service number 478.

FIVE-MODE KEYBOARD

A five-mode sending terminal introduced by Curtis Electro Devices offers keyboard origination of Morse, ASCII, and Baudot codes in addition to being a paddle keyer, code practice generator, and contest memory unit. Called the KB-4900, this unit blends the power of a microprocessor with the ease of analog controls and indicators.

Features include a 256-key sending buffer and a 256-key soft-sectored message memory with up to four callups. The two-key lockout and fully debounced keyboard offers all domestic, European, and many commercial prosigns for CW, all Baudot characters, and upper- and lowercase ASCII communication characters. Automatic line length control, word wraparound, hold, and backspace are included. All LTRS and FIGS shifts are automatic in the Baudot mode.

Analog controls (pots) are provided for speed, weight, pitch, and volume, and meters display Morse speed and buffer status. Output is via mercury relays for the keyline and PTT (or KOS) line. RTTY output is a loop switch.

The message memories include three fixed preambles (CQ, CQ TEST, ID and QRZ) plus up to four programmable memories. An automatic serial number can be inserted in any memory or the buffer for contests. An optional real-time clock inserts 24-hour time in the buffer of memory.

The code-practice mode generates either true random (no answers) or pseudo-random five-letter Morse groups in eight lists (with answers). Character spacing can be expanded for easier learning. Powered by either ac or +12 V dc, the KB-4900 measures 12" × ½" × 4½" and weighs 5 lbs.

For detailed specifications, write *Curtis Electro Devices, Inc., Box 4090, Mountain View CA 94040; (415)-494-7223.* Reader Service number 476.

Five-mode keyboard from Curtis Electro Devices.

HYBRID IC USES TOUCH-TONE® PHONE FOR DATA INPUT

The Teltone M-927 accepts all 16 dual-tone multi-frequency (DTMF or touch-tone) digits, plus rotary dial pulses, from a telephone, radio, or other source. Logic output drives transistor, low-power Schottky TTL, MOS, or CMOS devices. When coupled with a CMOS driver, the M-927 can operate a digital display.

DTMF signals can be transmitted anywhere in the world over the switched telephone network because DTMF digit frequencies fall in the voice band. Access to data entry and control devices is literally universal. The Teltone M-927 is an easy and reliable way to interface telephones to data processing, control, and monitoring equipment, and to consumer-oriented financial service systems. Pin-selectable logic outputs include: binary, 2 of 8 (2 of 7), 1 of 12, or blank. Strobe, three convenient clock frequencies, signal presence, and DTMF/dial pulse mode indications are provided.

The 40-pin DIP hybrid contains a proprietary Teltone LSI device, dial-tone filters, band-split filters, and clock circuits. It requires only a 3.579-MHz color burst crystal and a single 12 V dc source to become a complete decoder circuit. *Teltone Corporation, 10801-120th Avenue N.E., Kirkland WA 98033; (206)-827-9626.* Reader Service number 477.

HIGH PERFORMANCE TOWER GUYS

Philadelphia Resins Corporation announces a new line of PHILLYSTRAN® high performance tower guys which shows significant improvement in performance over previous offerings, particularly in the area of low stretch.

PHILLYSTRAN® has been used successfully by over 400 commercial broadcast stations since its introduction in 1973. In these applications, PHILLYSTRAN® was chosen over competitive materials such as wire strand and GRP rod primarily because of its combination of light weight, high strength, good dielectric properties, and ease of installation. Recently a survey conducted among tower manufacturers, riggers, and station engineers showed that minimizing tower deflection is the most important concern in selecting guys. With this in mind, Philadelphia Resins Corporation initiated a program to improve the performance of its tower guys. The result is an entirely new family of cables called PHILLYSTRAN® HPTG which is specifically designed to be used for supporting large towers.

The major improvement found in PHILLYSTRAN® HPTG is its much lower elongation, not exceeding 0.3% at usual working loads and less than 1% at tensile loads up to 50% of the minimum break strength. This low elongation together with negligible creep will decrease tower deflection and also makes possible a simple tensioning procedure when installing the guys. In addition to favorable stretch characteristics, PHILLYSTRAN® HPTG shows enhancement in other areas. Diameter for diameter, it is stronger than extra-high-strength galvanized steel strand and also enjoys a three- to fourfold advantage in weight per foot.

For further information, contact *Philadelphia Resins Corporation, 20 Commerce Drive, Montgomeryville PA 18936; (215)-855-8450.* Reader Service number 481.

MOLDABLE PLASTIC COAX-SEAL

COAX-SEAL is a pliable, plastic material which is wound over coax fittings of any size or shape and then hand-molded to provide a long-lasting, flexible, waterproof and dustproof seal. This new material stays flexible at temperatures from −25° F to 350° F.

COAX-SEAL maintains its sealing qualities regardless of movement of the coax and adheres to polyvinyl or vinyl coax jackets. The material allows the quick decoupling of a coax fitting and also the resealing of the fitting using the same material. Application is by hand—roll off approximately 6" of COAX-SEAL, remove backing paper, wrap starting at outer covering, and work towards fitting, allowing a one-half overlap as you go. After the wrap is completed, gently knead to form a smooth surface and to force out any air.

COAX-SEAL comes in rolls 60" long, 1/8" thick, and 1/2" wide. 50-foot industrial rolls also are available. *Universal Electronics, Inc., 1280 Aida Drive, Reynoldsburg OH 43068; (614)-866-4605.* Reader Service number 479.

DEALER DIRECTORY

San Jose CA

Bay area's newest Amateur Radio store. New & used Amateur Radio sales & service. We feature Kenwood, ICOM, Azden, Yaesu, Ten-Tec, VHF Engineering & many more. **Shaver Radio, Inc., 1378 So. Bascom Ave., San Jose CA 95128, 998-1103.**

KENWOOD—YAESU—DRAKE

The world's most fantastic amateur showroom! You gotta see it to believe it! **Radio Wholesale, 2012 Auburn Avenue, Columbus GA 31906, 561-7000.**

Boise ID

Adzen, Amidon, Ameco, ARRL, B&W, Callbook, Collins, CushCraft, Dentron, Hustler, ICOM, Jim-Pak, KDK, MFJ, NPC, Nye, Sams, SST, Swan, Ten-Tec, Wanzer, Wilson. **Custom Electronics, 1209 Broadway, Boise ID 83706, Bob W7SC 344-5084.**

Preston ID

Ross WB7BYZ, has the Largest Stock of Amateur Gear in the Intermountain West and the Best Prices. Call me for all your ham needs. **Ross Distributing, 78 So. State, Preston ID 83263, 852-0830.**

Terre Haute IN

Your ham headquarters located in the heart of the midwest. **Hoosier Electronics, Inc., 43B Meadows Shopping Center, P.O. Box 2001, Terre Haute IN 47802, 238-1456.**

Littleton MA

The ham store of N.E. you can rely on. Kenwood, ICOM, Wilson, Yaesu, DenTron, KLM amps, B&W switches & wattmeters, Whistler radar detectors, Bearcat, Regency, antennas by Larsen, Wilson, Hustler, GAM. **TEL-COM Inc. Communications & Electronics, 675 Great Rd., Rt. 119, Littleton MA 01460, 486-3040.**

St. Louis MO

Experimenter's paradise! Electronic and mechanical components for computer people, audio people, hams, robot builders, experimenters. Open six days a week. **Gateway Electronics Corp., 8123-25 Page Blvd., St. Louis MO 63130, 427-6116.**

Phila. PA/Camden NJ

Waveguide & coaxial microwave components & equipment. Laboratory grade test instruments, power supplies. Buy, sell & trade all popular makes, HP, GR, FXR, ESI, Sorensen, Singer, etc. **Lectronic Research Labs., 1423 Ferry Ave., Camden NJ 08104, 541-4200.**

Syracuse–Rome–Utica NY

Featuring: Kenwood, Yaesu, ICOM, Drake, Ten-Tec, Swan, DenTron, Alpha, Robot, MFJ, Tempo, Astron, KLM, Hy Gain, Mosley, Larsen, Cushcraft, Hustler, Mini Products. You won't be disappointed with equipment/service. **Radio World, Oneida County Airport-Terminal Building, Oriskany NY 13424, 337-0203.**

Mocksville NC
AMATEUR-REPAIR

Quality Service, reasonable rates, all brands. Now USA KDK repair center. **Amateur Radio Repair Center of IEC, Inc., 79 Town Square, Mocksville, NC 27028, 998-2627.**

Columbus OH

All major brands featured in the biggest and best ham store for miles around. Come in and twist the knobs before you buy. **Universal Amateur Radio, Inc., 1280 Aida Dr., Reynoldsburg (Columbus) OH 43068, 866-4267.**

Houston TX

Experimenter's paradise! Electronic and mechanical components for computer people, audio people, hams, robot builders, experimenters. Open six days a week. **Gateway Electronics Inc., 8932 Clarkcrest, Houston TX 77063, 978-6575.**

San Antonio TX

Complete 2 way service shop. Call Dee, W5FSP. Selling Antenna Specialists, Avanti, Azden, Bird, Hy-gain, Standard communications, Genave, Henry, CushCraft, Dielectric, Hustler, ICOM, MFJ, Nye, Shure, Swan, Tempo, Ten-Tec and others. **Appliance & Equipment Co., Inc., 2317 Vance Jackson Road, San Antonio TX 78213, 734-7793.**

DEALERS

Your company name and message can contain up to 25 words for as little as $150 yearly (prepaid), or $15 per month (prepaid quarterly). No mention of mail-order business or area code permitted. Directory text and payment must reach us 60 days in advance of publication. For example, advertising for the May issue must be in our hands by March 1st. Mail to 73 Magazine, Peterborough NH 03458. ATTN: Nancy Ciampa.

W2NSD/1 NEVER SAY DIE

editorial by Wayne Green

DOING SOMETHING ABOUT IT

There is one basic reason why the ham market has been soft during the last year and it has little to do with the job market, stagflation, or the recession. The main reason why hams have not been buying very much ham gear lately is that there have been far fewer new hams...and this means fewer enthusiastic newcomers looking for fun.

If amateur radio was growing at the rate of 11% as it did before the proposal of "Incentive Licensing," we would be welcoming about 75,000 new Novices a year. That would represent the 11% growth plus those needed to make up for the dropouts and silent keys. That represents a buying market of over $100M. Even when you spread that amount around among about 200 ham stores, that represents another half million dollars in sales for each store.

Tufts Electronics has moved things around in their store and set up a classroom for teaching the Novice course. It has been so successful that they are now planning for General and Advanced courses as well. They have been charging $35 for the course, which runs for ten weeks, one night a week. Judging from the interest shown in the courses, Tufts is now estimating that they will be able to license about 50 new hams a month.

The money for the courses goes for some of the instruction materials, some for the instructor, and the rest for advertising and overhead. Clubs running Novice courses have found that the more a student has invested in a course, the more likely he is to complete it. That makes sense, when you think about it, but the anti-profit nuisance who turns up now and then wanting the classes to be free louses it up for everyone.

Perhaps you can talk this over with your local ham supplier and get him to set up Novice courses. Remind him that each Novice historically buys about $1,500 in ham gear and books, so it is well worth his while to see that we have as many newcomers as possible. We should also do all we can to get our clubs to have Novice classes and try to empty out the high schools for prospects. Remember that about 80% of these teenage Novices will decide to make electronics their career ...and they just might be the answer to the loss of technology to Japan.

One more reminder: The *73* series of code tapes is the world's fastest way to learn the code...and the *73* theory course is the best one on the market because it stresses learning the theory rather than memorizing questions and answers. These are ideal teaching adjuncts to any Novice class.

RADAR CRUISE CONTROL

One of the benefits of the recent interest in police radar and its detection has been a good deal of research on the use of radar for cars. RCA, in particular, has been working on the problems and has come up with a system which would enable a car to automatically follow the car ahead, keeping pace with it. This is a small radar unit which is connected to the cruise control of a car, either allowing the following of the car ahead or else maintaining speed until a car is detected ahead, at which time the radar would disable the cruise control automatically.

Speaking of radar, the car magazines all seem to be of the opinion that Reagan will be backing an end to the 55-mph speed limit, putting the responsibility for speed control back on the states. Many of the western states are not at all enthusiastic about the limit.

There seems to be convincing proof that our government agencies have been covering up the facts about the speed limit and have been supplying us with highly distorted reports on the supposed benefits. Rather than either saving lives or oil, the speed limit may have both increased traffic fatalities and saved hardly any oil. The major benefit has been to the makers and dealers selling radar units to the police...and detectors to the public. Cozy arrangement.

The other major benefactors of the speed limit have been the CB industry and the communities which have gotten the take from the speeding tickets...billions of dollars.

Some psychologists have pointed out that one of the results of making virtually everyone a criminal is to alienate the public from the police and thus encourage crime...and reduce the cooperation needed.

Perhaps the bright spot of all this will be the developments we can see coming as a result of the radar research.

SAROC

Having been unable to locate anyone who attended, I'm going by reports from third parties: UGH.

Not only were there fewer than 1,000 in attendance, what few there were apparently were

TECH WIZARDS

We seem to be getting more and more technical questions whose answers require more and more of our time which we seem to have less and less of. We would like to revive the Technical Aid Group concept which appeared here 10 years ago.

Please, you wizards out there who *want* to help (without compensation), send us your qualifications (experience, degrees, area of expertise, if any, etc.) and complete address. Then when readers have questions they can talk to an expert.

Don't take this lightly—some questions are difficult and will require some digging. But if you can help, you might save someone a lot of grief.

Write to Editorial Offices, *73 Magazine*, Pine Street, Peterborough NH 03458, attention: Tech Wizards.

TRAVELING HAMS

We believe that there are many interesting stories related to ham radio across this wide world that are begging to be told. When you do travel, keep that in mind. You may be the only outsider who is a ham to visit a hidden valley somewhere. Neither *73* nor any other amateur radio publication has the staff to do this adequately; we are depending on you.

When you have a trip coming up, let us know. We may have heard about something along your route that may be of interest to us all. You might even make a few dollars to put toward your next trip. So, put a note pad and pencil in your camera case and start thinking like a roving reporter.

If you are interested, send your travel plans to Editorial Offices, *73 Magazine*, Pine Street, Peterborough NH 03458, attention: Traveling Hams.

siphoned off by a competing event put on by the local ham club, which has not been silent in its bitter feelings about the SAROC hamfest . . . an event put on mostly by one chap for profit . . . and supported almost solely by *Ham Radio* magazine.

The show did get a great review in *HR*'s Half Right Reports, thus preserving their record for objectivity. Will there be another debacle next year? It seems unlikely.

VEGAS

Though I didn't go to the SAROC mess this year, I did have to get out to Vegas for the Winter Consumer Electronics Show (CES) a couple of days later. The weather was perfect and the town was crowded with about 60,000 attending the CES. With the casinos vying with each other to provide low-cost eats, you can do very well in the town on about $6 per day. Even the local people come to the strip to get in on the $1.49 breakfast buffets.

Other than that, most of the things in Vegas are so tacky that I really dislike the place. The casinos are packed most of the day and night with people pulling the levers of the slots. Are they having fun? I watched several hundred of them and I saw not one smile. Even when the jackpot would eventually dump on them they accepted it stoically and went back to seeing how fast they could get the coins back into the machine.

At the airport, while I was waiting for my plane, I watched a shabbily-dressed couple get $100 in dollars and start feeding them into a slot machine. By the time I'd finished my ice cream, the $100 was gone. I never saw one sign that either of them was enjoying the experience. They just stood there silently, as though hypnotized, sliding in the dollars, three at a time.

It is not really difficult to win in Vegas . . . at least until they get to know you . . . but you have to know what you are doing and spend some time learning how. I've written about this in one of my other magazines in more detail. Obviously, before you tackle the professionals, you want to have your system not only perfected, but very well practiced. This is where the computer comes in . . . affording you practice without having to pay for it. It is far better to learn for free and take your lumps than to try to get your gambling education at $2 a throw.

Quite a number of people have come up to me at shows and tried to argue that you can't really win at gambling in Vegas. When I pry into their knowledge of the subject, I find that they know virtually nothing about it.

AWARDS

Bill Gosney WB7BFK
Micro-80, Inc.
2665 North Busby Road
Oak Harbor WA 98277

I wish to thank the many readers who have supported the *73* Awards Program and this Awards column over the past year and a half. I've received letters from all over the world supporting both projects.

In answer to the many letters received recently, the *73* Awards Program is quite extensive. As you read through the September and October, 1980, editions of *73*, you see featured nearly twenty individual awards being made available to licensed amateurs. We would like to cater to your many ideas for adding a few more awards to the program, but we have to limit our portfolio so that it is manageable by the staff. As we all know, *73 Magazine* is only one function of the Peterborough crew!

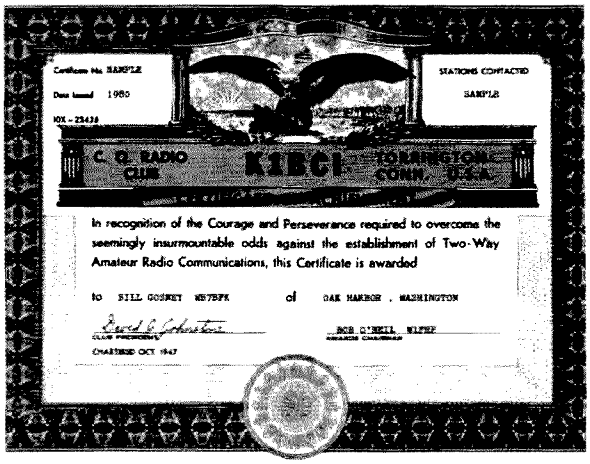
Please, don't let my comment discourage you. You people have a lot of super ideas for different awards. Personally, I would recommend that you initiate and fund your award concept locally. What a great way for a radio club, for example, to gain international recognition! Take the Whidbey Island DX Club...with the founding of the International Island DX Award, we have seen applications made from even the rarest of countries and stations. We've seen the popularity of the club and its DX Award grow significantly over the past three years to where now it is the center of attraction.

A radio club award can mean a way of strengthening the club's treasury. Those projects which previously were restricted due to finances now can become reality. The easiest part of it all, once you have your award program organized and can send your rules to me to publish in this column, is just standing by...within a month you'll begin seeing letters of application pouring in.

The most important comment I can offer about a newly-founded award is that it has to be something different to be in demand. So, give your award idea some thought. Plan your requirements with the thought in mind that your award is not for everyone. Make the rules somewhat difficult, yet not too restrictive. Don't make the award so simple that you practically give it away. If an operator doesn't have to work towards a goal, the certificate on the wall won't be of any value to him or those who see it on display.

Finally, I would like to see clubs getting involved with award programs on a larger scale. The majority of award sponsors seem to be major magazine publishers and national radio societies. Somewhere along the line, most of the clubs lost their confidence and only a few have taken the initiative to design an award and offer a challenge to award seekers of the world.

Perhaps now clubs will recognize the significance award programs have to an active group. Why not form a committee and consider such an endeavor this week?



CQ AWARD

The CQ Radio Club of Torrington offers a certificate for contact with its club members. This is open to any amateur station on any band, any mode, at any time.

To qualify, amateurs within Connecticut must make 15 contacts with members; other stateside amateurs need to contact only 10 member stations; DX stations must establish 5 member contacts.

There are no charges for this award; however, donations to offset postage would be appreciated. Send your list of contacts to: Robert J. O'Neil W1FHP, Awards Manager, Hard Hill Road, Bethlehem CT 06751.

THE HEX AWARD

Paul Hilton N3BCZ recently wrote and provided me with details of an award being sponsored by the Lancaster Radio Transmitting Society, Inc. The award is a beautiful hand-colored certificate, authenticated by the officers of the Lancaster organization.

To qualify, applicants must make contact with at least thirteen Lancaster County radio operators. There are no mode restrictions, but contacts via repeater are not valid.

To apply for the award, send your QSL confirmations to the club trustee. Be sure to enclose sufficient postage for the safe return of your cards. In his letter, Paul failed to mention if there was an award fee. It is assumed there is not. You may forward your application to: Robert Wenger, 402 S. State Street, Ephrata PA 17522.

If you are an active county hunter, which a heck of a lot of our readers are, you might take a hard look at four very challenging awards being offered by Ray Teeter N2RT.

THE UNITED STATES OF AMERICA COUNTY AWARD

The USA County Award is available to applicants who can meet the requirements of any of the 12 award categories.

There is a category for each call district, and an applicant must work the required number of counties in that district to qualify.

1st call district—67 counties
2nd call district—83 counties
3rd call district—94 counties
4th call district—749 counties
5th call district—584 counties
6th call district—58 counties
7th call district—257 counties
8th call district—226 counties
9th call district—266 counties
10th call district—681 counties
Alaskan call district—4 counties (judicial districts)
Hawaiian call district—5 counties

When applying, you *must* state which call district you are applying for. Claiming all call districts requires 12 applications, and the recipient also will receive a nice trophy.

For each Call Area Award, there are three award classes. Class A—all counties in the call area worked; Class B—⅔ of the counties worked in the call area; and Class C—⅓ of the counties worked in the call area.

To apply for the USA County Award, prepare a list of claimed contacts in order by county within each call area. Be sure to list the usual logbook information, including the county and state of the contact. Do not send QSL cards! Have your list verified by at least two amateurs or a local radio club secretary. While there are no mode or band restrictions for this award, you may request endorsements and receive recognition at no additional charge if a request for such is made at the time of application.

For each Call Area Award being applied for, enclose an award fee of $1.00 and forward to: Ray Teeter N2RT, RD 2, Canaan Heights, Locke NY 13092.

CHN MOBILE ACHIEVEMENT AWARD

Also made available by Ray Teeter, the CHN Mobile Achievement Award is offered in three award categories.

To qualify, applicants must either (1) work mobiles in all the counties of any one state, (2) work the same mobile in all counties of any one state, or (3)

CONTESTS

Robert Baker WB2GFE
15 Windsor Dr.
Atco NJ 08004

QRP ARCI ANNUAL QSO PARTY

2000 GMT April 18 to
0200 GMT April 20

The contest is open to all amateurs and all are eligible for the awards. Stations may be worked once per band for QSO and multiplier credits.

EXCHANGE:

Members—RST, state-province-country, and QRP number.

Non-Members—RST, state-province-country, power input.

SCORING:

Each member QSO counts 3 points. Non-member QSOs are 2 points, and stations other than W/VE count 4 points each. Multipliers are as follows: More than 100 Watts input, ×1; 30-100 Watts, ×1.5; 10-30 Watts, ×2; 3-10 Watts, ×4; 1-3 Watts, ×6; less than 1 Watt input, ×10.

Final score is total QSO points times total number of states-provinces-countries per band times the power multiplier.

FREQUENCIES:

Novice—3710, 7110, 21110, 28110.

SSB—1810, 3985, 7285, 14285, 21385, 28885, 50385.

CW—1810, 3560, 7040, 14060, 21060, 28060, 50360.

Try SSB on even hours, and don't forget Novice frequencies.

AWARDS:

Certificates to the highest scoring station in each state, province, or country with two or more entries. Other awards will be given depending on activity. One certificate to highest scoring Novice/Technican overall. One certificate for the station showing three skip contacts using the lowest power.

LOGS AND ENTRIES:

Send full log data, including full name, address, and bands used, equipment, antennas, and power used. Entrants desiring results sheet and scores, *please* enclose a business-sized envelope with sufficient return postage. Logs must be received by May 20th to qualify. Send all logs and data to: QRP ARCI Contest Chairman, William W. Dickerson WA2JOC, 352 Crampton Drive, Monroe MI 48161.

YL ISSB QSO PARTY—PHONE

0001 GMT April 18 to
2359 GMT April 19

Two six-hour rest periods are required. Operating categories include: single operator, DX/WK teams, and YL/OM teams. All bands will be used, and the same station may be contacted on different bands for contact points but not as country multipliers. Two meters may be used, but contacts must be direct and not through repeaters.

EXCHANGE:

Name, RS, SSBer number, country, state, and partner's call. If no partner, leave blank. If non-member, send "No Number."

FREQUENCIES:

3925, 7290, 14332, 21373, 28673. Listen for DX on 3765 and 7090. Listen for VK on 3690 on 75-meter phone, as their top frequency is 3700. It is requested that stations spread out to relieve congestion on 14332. Use frequencies from 14280 to 14345. Remember the nets on 14313 and 14336. Also DX stations use 14160 to 14190 for contacts among themselves.

SCORING:

Score five points for each member contacted on any continent. Non-member contacts count one point. Only member station contacts count for multipliers. Multipliers are each state, country, and province. Also, each team contacted, but

FCC

TYPE-ACCEPTANCE REQUIREMENTS EXTENDED FOR EXTERNAL RADIO FREQUENCY POWER AMPLIFIERS (DOCKET NO. 21117)

The Commission has decided to extend for an indefinite period its type-acceptance requirements for external radio frequency power amplifiers of the kind used to amplify Citizens Band radio transmissions illegally.

The Commission instructed its staff to draft an order extending the type-acceptance and related technical requirements indefinitely. The requirements were adopted in 1978, effective for three years, to cope with the problem created by the large number of amplifiers being marketed and promoted for use in and around the CB frequencies. External amplifiers of the sort used to amplify CB signals illegally can cause serious interference to TV and radio reception.

Type acceptance, in this case, requires submission of a sample of the model amplifier to the FCC for approval, along with technical data, before it is manufactured and placed on the market. The number of prototype units that can be manufactured in preparation for submission for type acceptance is limited to 10.

The requirements apply to all amplifiers and amplifier kits capable of operation below 144 MHz. They cover most amplifiers used in the Amateur Radio Service.

The Commission said numerous manufacturers and distributors of amplifiers designed for illegal operation have ceased manufacture and marketing since the requirements were adopted, though some are continuing.

The effectiveness of the type-acceptance requirements in halting promotion of amplifiers for illegal applications indicates that they should be continued, it said. Notice of the continuation was given in the order that originally implemented the type-acceptance requirement.

Action by the Commission, December 18, 1980, by Second Report and Order (FCC 80-750). Commissioners Ferris (Chairman), Lee, Washburn, Fogarty, and Brown.

CORRECTIONS

In the January, 1981, Review section, the first two TS-820 mod kits (front end and balanced mixer) were incorrectly sourced to S-F Amateur Radio Services. These mods are, in fact, produced by W6TOG, and are available through authorized distributors (S-F is not one). All mail-order inquiries should be directed to the address given below. Both the QRO kit and the Magicom board are available still from S-F at the address given at the end of the review.

Most of us thought that the world had learned its lesson about appeasement when Neville Chamberlain and Edouard Daladier engineered the Munich Pact, thus preparing the way for Adolf Hitler's rapacious appetite for territorial aggrandizement. We thought that appeasement had been thoroughly discredited as a bankrupt tactic, unworthy strategically and unworkable from a practical sense.

It appears that we have not learned that historical lesson, and we may be compelled to relearn it.

We show overweening leniency toward parasites and criminals; we extend the hand of friendship (generally prompted by either economic or political expediency) toward foreign nations which despise us; we lower academic standards so that unqualified boobs can occupy space in our universities, and, closer to home, we grant concessions to the undeserving in amateur radio.

Two things happen when you appease. You sharpen the recipient's appetite for more, and you make it unnecessary for him to appreciate what he has, for he comes to the swift conclusion that he deserved to get it all the time. Giving something for nothing is a certain prelude to disaster.

Through the years, we have witnessed a gradual frittering-away of quality in favor of quantity, and nowhere is this more clearly evident than in ham radio. The implementation of the "mail order" license was a costly mistake. Likewise, the reinstitution of Incentive Licensing was a kick in the teeth, not only to the Amateur Service, but to every ham holding a General class ticket, for it arbitrarily deprived him of privileges once fairly earned and rightfully enjoyed. At the same time, it fell far short of the intended mark, which was to encourage upgrading on a wide scale.

The sad fact is that only a small proportion pursued the golden goal of Extra class. They went as far as Advanced simply because their sole interest in upgrading was to continue operating on accustomed frequencies. I have asked literally thousands of hams why they upgraded, and most had not done it in order to improve skills or knowledge but merely in order to be able to work DX or avoid the congestion in the crowded General portions. Certainly the piddling few kilohertz of sequestered space in the CW portions and in 15- and 75-meter phone bands did not strike anyone as all that attractive, at least not when measured against the difficulty of learning Extra class theory and increasing the CW speed up to twenty words per minute.

I cannot speak for all amateurs, of course, but as a DXer of long standing, I can state with conviction that to those who share that interest with me, there is little point in acquiring the Extra; it is meaningless in real terms.

Newington, ever-obsessed with the idea of recruiting more and more members, has sold itself a delusion: that there is an unlimited pool of potential amateurs out there, and that any and all of them should be recruited through any means, even code-free licensing. Perhaps amateur radio has gained several good people who were at first unqualified, but it is even more likely that there is a huge army of lids who could never be anything but a detriment, no matter what was done for them.

All that separates the deserving from the undeserving is the FCC examination. And for the ARRL to keep granting credence to the idea of an "entry level" code-free license (a cryptic term which means a giveaway) is an absolute abomination, a breach of faith with every League member. The major contributing factor toward the mess on 27 MHz is that anyone can apply and get a license without lifting a finger to prove that he is qualified. The regulations may call for the CBer to possess a copy of the appropriate rules, but he is not required to read them or to be familiar with their provisions. He does not have to know anything, nor does he have to demonstrate his willingness to learn anything. All he needs to do is to buy a piece of equipment, hook it up to an antenna, plug it into the wall socket, and begin yammering into a microphone.

And now the powers that be are again proposing that the door be opened to more unqualified "space cadets," so that they can bring their ignorance into the Amateur Service. Pursuant to a request by FCC Chairman Ferris, and with the support of three "high level" officials on the Commission Staff, a Notice of Proposed Rulemaking is being drafted which is intended to implement a waiver of the code for amateur licenses.

That this ostensibly is aimed at bringing in those who are involved in computer science is altogether beside the point. Of course there is an important future in amateur radio for all sorts of applications of the new digital techniques. An editorial in *QST* for June, 1980, mentioned several areas: station control, contest logging, satellite applications, repeater "bookkeeping," orbital predictions, azimuth-elevation tables, signal processing, automatic error correction, antenna design computations, direction-finding techniques, and message handling. But, as I say, all this is beside the point. The fact is that the doorway to ham radio has never been closed. Anyone with a desire to become an amateur can acquire the necessary knowledge and skill. The only thing that ever stood in the way was an applicant's laziness and inertia.

But the FCC operates on the present-day assumption that high standards are set up as a deliberate bar to the entry of the broadest possible number, that difficult criteria are evidences of some desire to exclude, and are therefore undemocratic. And, instead of opposing this with all the strength at its command, we see our ARRL expressing uncertainty with respect to amateurs' feelings in the matter. I will wager anything that with the possible exception of a few isolated bubble-headed utopian idealists, the huge majority of U.S. amateurs firmly oppose the granting of any code-free license.

Some insist that because some, even most, have no use for CW, it ought to be abolished as a prerequisite. I say, bullfeathers! It may not be in general use by the majority; I won't argue the point. But to me, its chief purpose is to test the willingness of applicants to earn the license.

There are some individuals who can't qualify for driving and flying licenses. They are incapable of sufficient coordination, or their minds can't grasp the written material. But you don't see anyone proposing an "entry license" for them. You don't see bar associations endorsing an "entry level" so that incompetents can practice law, nor do you see a State Medical Board asking for changes that would permit the non-qualified to acquire "entry level" licenses to practice obstetrics or neurosurgery!

Yet, this is precisely what proponents of such schemes are really driving at. Do you seriously believe that they do so because they are sincerely interested in the growth and future of amateur radio? Or is it somehow tenuously connected to a bonanza in the sales of equipment to new licensees? Not that I object to that; it is important to our free enterprise system. But, at the same time, nothing prevents anyone from buying the *License Manual* in order to qualify for a

NO-CODE LICENSE?

Here's your chance to speak up! Send us a postcard with your **Yes or No** answer to this question:

Should there be *any* form of no-code license in the Amateur Service?

Mail your reply to Editorial Offices, *73 Magazine*, Pine Street, Peterborough NH 03458.

RTTY LOOP

Marc I. Leavey, M.D. WA3AJR
4006 Winlee Road
Randallstown MD 21133

April may be the month for fools, but the biggest fool of all around here would be me if I ignored your letters and questions. So this month let's turn to the mailbag.

Some time back, I mentioned that Dave Lundquist WA2UWK was in need of information for the Lenkurt 25-A demodulator that he had acquired. Indications are that Dave got all the information that he asked for, and more. With the help of Sheldon Daitch WA4MZZ and Rich Strehlow KAØCSG, and who knows how many others, both Dave and I now have a bit more information on the Lenkurt.

This unit was (is?) in use by various wire services to distribute signals on slow-speed teleprinter channels. It is configured to allow tone pairs from around 300 Hz to 7 kHz, center frequency, to be used. Thus, several different signals could share the same line, using different audio tone frequencies, with the differentiation made by the receive filter in the Lenkurt unit. Hopefully, Dave will be able to adapt the thing to amateur RTTY. Good luck, Dave!

There seems to be quite a bit of interest in connecting various teleprinters to low-level TTL circuits. A1C Randy L. Bray, stationed at Bergstrom AFB, Texas, writes that he tried to drive a compact Model 28-KSR Teletype® from a demodulator yielding a TTL-level output. A slight lack of drive there, no? Well, being the industrious serviceman that he is, Randy went on to devise the circuit shown in Fig. 1. This uses a matched pair of 4N25 optoisolators to convert the TTL level to a plus-minus six-volt swing, suitable for driving the polar input of his printer. To take care of occasional upside-down stations, he uses one section of a 7404 TTL hex inverter, which may be switched in to up-side-up the upside-down renegade. Looks like a nice piece of work, Randy.

Along the lines of interfacing, Reginald Theriault, from Rimouski, Quebec, is currently using a Model 28-ASR Teletype and a HAL ST-5 demodulator on 60-wpm, 5-level RTTY. He has recently come by a video terminal and wonders how to use it on RTTY. Reg, the terminal you describe is set up, as are most terminals, to use the eight-bit ASCII code, described in RTTY Loop a few months back. As a serial RS-232 output is available, the physical connection of the terminal to a demodulator such as the ST-5 should not be too hard. However, you will be running ASCII, not Baudot/Murray code. Although this is legal in the United States, I am not sure about Canada's viewpoint. Further, most RTTYers are still using Murray/Baudot (try to keep things fair!). There are two main ways to convert to five-level code, if you want to: a stand-alone hardware conversion or a computer.

The hardware conversion would use a UART to input the serial data and convert it to parallel, a ROM and associated chips to look up and change code groups, and another UART to output the transformed code, perhaps at a different speed. This method is cheap, it works, and several schemes have been published in *73* through the years.

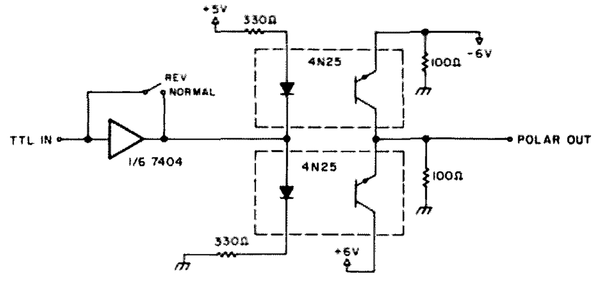

Fig. 1. TTL-to-polar conversion.

A computer may be programmed to do the same conversion, from one code to another and back again, and will do it just as well as a simple board, at many times the cost. But what you gain is some intelligence in the conversion. The computer can provide features such as message buffers, automatic identifiers, and other bells and whistles which make operating a real pleasure. Now, I don't think I would run out and buy a computer just to run RTTY, but once you have one you won't believe how many new uses you can find.

This leads us to another question: which computer? Well, from the RTTY point of view, I really don't think that matters much. My biases run toward the 6800 family, but that is because I have one and have written quite a bit of software for it. The TRS-80, by Radio Shack, is clearly one of the most popular microcomputers on the market, spawning accessory suppliers and even whole magazines (have you tried *80 Microcomputing* yet?). A typical question comes from John. T. Gubernard K2LSX, of Bergenfield, New Jersey, who writes that he has a TRS-80 and is looking for ways to get on the air with it.

Guess what else the mail brought? One of our *73* advertisers, Vic Frump K8EXJ, passes along information about his Bit-Byter RTTY system for the TRS-80. This system is designed for either a Level I or Level II computer and has quite a list of features, including split-screen operation, with received information scrolled in the bottom two-thirds of the screen and the transmit buffer in the top third, automatic RTTY and CW identification, single-key CQ, RY, or QBF, and 60- or 100-wpm operation. The unit keys the loop, so interfacing to most systems should be straightforward. Interested? Drop Vic a line at UHF Sales & Service Co., Route 1, Box 52A, Evans WV 25241. Be sure to mention RTTY Loop when you write, OK?

Pictures on RTTY is always a good topic, but, unfortunately, one which has caused quite a bit of concern in these pages in months past. As I write this (in January), there still is no word on the ongoing saga of Teleprinter Art, Ltd. There are pictures out there, however, and you don't have to pay for them! Russ Lawson K1MOU drops me a note that several active hams have reams of pictures they will gladly send to anyone, over the air. Ken WA4MNT, in St. James City, Florida, says that he has quite a few, and W. E. Symons K4IH passes along a similar list as long as your arm.

Most letters I get are questions or requests for this and that bit of information. I would like to acknowledge one this month that was just a nice note. I can remember back a few years, when I was an intern, how tight my time was and how precious every spare moment became. This schedule only gets worse the further into the system you go, through residency and Fellowship. That is why this note, from Joseph R. Salvatore, M.D., now a Fellow at Roger Williams General Hospital in Providence, Rhode Island, means so much. Joe was one of my interns a few years ago, and I lost track of him when he left the area to further his education. I don't know what his callsign is now, but I am sure that he does not have much time to operate. Thanks for reading the magazine, Joe, and best of luck.

Our sister publication, *Kilobaud Microcomputing*, has been giving quite a bit of space to communicating over telephone lines. These Computer Bulletin Board Systems (CBBS) now form a viable means of getting information across the country without worrying about propagation conditions. Users of 6800 systems might be interested in an article in the February, 1981, issue which details the method I use to hook up to the CBBS locally. By the way, if you want to leave me a message, you might try the Baltimore Micro-Mail Service, at (301)-655-0393, calling *only* between the hours of 10 am and 10 pm, eastern time, or the Prodigy system, at (301)-337-8825, available 24 hours a day. Both of these systems are ring-back, CP/M-based computers. To access, call the number, let the phone ring once, then hang up and dial again. The computer will answer when you call back in.

Going to look at another piece of equipment next month. What is it? You may not think you need it, but once you've bought one you wouldn't be without it. Curious? Don't miss next month's RTTY Loop!

LETTERS

AMATEUR RADIO DAY

About 40 amateurs live in this northwest area of Arkansas, around Rogers. We have secured through the Official Centennial Commission, Saturday, May 9, to be set aside as Amateur Radio Day, as part of the events during the summer. Please help us celebrate that day by working one of the Official Centennial Amateur Radio Stations. The K5BP call letters will be used on about 7,283 kHz LSB or 21,363 kHz USB from 1400 UTC to 2200 UTC. Send confirming QSL card with a #10 SASE to K5BP, Dept. 1881, General Delivery, Rogers AR 72756 to receive an Official Centennial Certificate.

Glenn E. Webster W5VIX
Rogers AR

DE PY2AA

We, from LABRE—Liga de Amadores Brasileiros de Radio Emissao—are glad to announce that there has been set up a beacon, here in Sao Paulo—SP—on the six-meter band, for propagation research purposes.

The beacon is on 50.055 MHz and has an output power of 25 Watts. The antenna is an omnidirectional ground plane which is about 25 feet above the ground level, on the top of the League building.

The format transmitted is a long dash, along with "de" and the call: — de PY2AA.

We would very much appreciate any kind of report; they can be sent directly to PY2AA—Beacon Project, PO Box 22, 01000—Sao Paulo—SP, Brazil.

We will keep you informed on all free local beacon activity.

Hugo Adelino da Silva PY2DSQ
Sao Paulo—SP—Brazil

AND WAYNE SAYS...

There seems to be quite a controversy over Dick Bash's publications, and the fire was recently fueled by Skip Tenney's editorial. If I remember correctly, you were quite enthusiastic about Dick's publications. We find we are being put on the spot by some of our customers after seeing Skip's editorial, and I am trying to feel out some of the more prominent members of the amateur fraternity to determine what their thoughts are on this whole issue.

Warren L. Spindler K2IXN
Ham-Radio World, Inc.
Oriskany NY

Yes, Warren, I have some thoughts on the Bash cheat books. I am not aware of ever having been enthusiastic about them. Indeed, I have refused from the first to allow Bash to advertise in 73, for which we are paying with the loss of about $1,000 per month. I'd say that we are putting our money where my mouth is.

The editorial in HR *about the Bash books was read with entertainment by many. If you will look back in the April, May, and June, 1980, issues of* HR *(and some in* HRH*), you'll find that their Ham Radio Bookstore advertised and sold the book they are now being righteous about. I refused to carry ads for the book or to handle it in our Radio Bookshop.*

As I understand it, HR *was enthusiastic about the Bash books up until they got a call from the FCC. The FCC has been very uptight over the books and I have heard that they called Tenney of* HR *and put it on the line: If he wanted any more FCC information for his Half Right Reports, he should stop advertising for Bash. The ads stopped and the info to* HRR *continued.*

The Bash books are not much worse than the old ARRL Q & A manual in that they strongly encourage the memorization of answers rather than the understanding of theory. I feel that this is bad for those who suck in on this easy way to their first license. This is why my license manuals emphasize learning the theory rather than memorizing answers. Memory quickly fails... and any change of questions quickly confuses applicants. If the theory is understood, not only is any test simple but the foundation for going ahead to higher classes of license has been laid.

The memory route leaves the Novice with no real comprehension of radio theory, so he is then committed to ever more difficult memorization as he goes for the General and Advanced licenses. His ignorance will immediately be perceived by anyone he talks with over the air, making the use of his license less than fun. You can't fool people into thinking you really are a ham when you aren't. They see through the sham.

The really sad part of all this is that there is nothing complicated about understanding the theory. We've had kids four years old able to comprehend it and pass the test. Yes, it takes a bit of time and thinking. You know, it is incredible how much effort people will devote to not having to think! You might get the idea that it is painful to think instead of it being one of the most exciting of human experiences.

Now, to answer your question ... if I were in your position, I would not *sell the Bash books. —Wayne.*

AN UNBIASED VIEW

Just finished reading Larry Kahaner's excellent article, "Who Really Invented Radio?," but found it to be a "floppy copy" of hundreds of other writings, with the exception of a few new names with numbers identifying the modern-day authority of early radio.

Like many others, I also agree that America's N. B. Stubblefield invented, manufactured, and demonstrated a wireless device that transmitted and received both music and voice *before anyone on this planet*, and, like L. H. Hortin, I am tired of explaining that today's radio, as we know it, is Stubblefield's "wireless telephone" transmitter/receiver, and not Signor Marconi's dot and dash performer, or even Tesla's electrostatic transmitter.

Furthermore, English scientific publications such as yours really invented the word *"radio"* —several years *after* Stubblefield's famous broadcast demonstrations—to describe any and all sources of energy that radiated and/or created heat. The truth of the matter is that Stubblefield's scientific "wireless telephone" terminology and achievements were lost to the world by the stroke of a writer's pen, confusing knowledgeable men of both that time and even now! Luckily, Murrayites such as Hortin, Johnson, and many others, who know the real story, still exist.

It would appear that those two radio shack jocks, Riley Ray and William Call (also known as W4LMF and KJ4W respectively), should have known that "wireless telephone" is radio, no matter how you look at it, feel it, broadcast it, or just plain hear it, before tattling Murray's local gossip to the world.

Troy Cory Stubblefield,
Grandson of N. B. Stubblefield,
and son of Oliver Stubblefield
Universal City CA

73 METHODS WORK

I've never written a letter to any magazine before, but I feel I must this time.

I have no technical background or training whatsoever that is electronics or radio-related. In fact, until 1979 I didn't even know how to use a soldering iron! Using your *73* code tapes and theory courses, I have progressed from Novice to Extra class since July of 1979 (just passed Extra class exams January 7, 1981). That's a period of a little over 1½ years, and there is no way I could have done it without the help of your code tapes and study guides.

I can't thank you enough for all that your organization has to offer. Your training and teaching aids are second to none. Keep up the good work and you'll make a lot of newcomers, like myself, very pleased.

Bob Burdick KA1DOS
Ayer MA

PEKING TRAVELS

I read your article in this January's *73* and I thought I should mention that I was in China in December, 1979, and at that time I saw several allband radios in the communes.

In Shanghai, at the Children's Palace (for bright kids), there was a room where the students were assembling transistor radio kits.

I stayed at the Peking Hotel in

REVIEW

KENWOOD TR-7800

I have operated a lot of different two-meter rigs in my short life, and I am picky. When I first saw the Kenwood TR-7800 two-meter FM transceiver at a show last year, I made several unkind remarks about the rig to my companions. "Ha!" I said. "Look at that ridiculous keyboard entry system. That won't work in the car!"

I now wipe the egg off my face and present my sincerest apologies to my friends, not to mention the poor tortured soul in the booth. This is one of the best two-meter rigs I have ever used! Kenwood has designed this rig to be at home in both base and mobile applications, which is no minor undertaking.

In a way, my first impression was right—the keyboard is not easy to use while driving. What I missed was that it is rarely necessary to use that keyboard at all. This rig is equipped with an extremely flexible memory system, which allows 15 frequencies and their transmitter offsets to be stored in memory and recalled with the push of a button on the microphone. The memories are maintained even when the power switch is off.

Add four AA nicads and the rig will remember your favorite frequencies when there isn't a 12-volt power supply for miles around. No more peering at a washed-out display while fighting rush-hour traffic. No more calling a friend feverishly while your rig is on the wrong offset. Groping for the MHz switch or the 5-kHz button also have been mercifully banished from the two-meter experience. In short, this rig offers just about everything the dedicated FMer could ask for—either in a mobile installation or as a base station.

TR-7800 (front view) with Bird Ham-Mate Thruline* Wattmeter.*

Basic Performance

It's no use having all these sophisticated features if the basic performance isn't up to snuff. Before we go any further, let's examine the 7800's performance characteristics.

The 7800 is very compact, measuring only 6-7/8" wide, 2-1/2" high, and 8-1/16" deep. Electronic performance is excellent. Actually, the design of the receiver and transmitter sections of the 7800 is very similar to that of its older brother, the TR-7625. Many improvements have been made, but the basic design is a tried and proven one. There appears to be some additional filtering in the receiver to increase selectivity, and more reliable finals were used in the transmitter output stage.

Southern New Hampshire is not what could be considered an rf saturated area, so the fact that we never encountered any intermod problems doesn't mean too much. Still, all indications are that the 7800 should handle intermod at least as well as any other top-quality synthesized rig. Squelch action was very sensitive and sharp, more so than other popular rigs we have tested. The squelch control can be set barely above the noise threshold, and weak signals will open the squelch, but noise won't. Received audio is excellent, both through an external speaker and through the larger-than-usual built-in speaker. Since the built-in speaker is top firing, you won't have any problems if you mount the rig on a shelf or the transmission hump of a car.

Transmitter deviation was set perfectly, as was the output of the DTMP encoder. The *73* repeater uses a digital tone decoder, and if the tone levels on a pad are set too high, the decoder rejects them. The TR-7800 has one of the few pads we have seen that doesn't need some adjustment to work properly.

Transmitter output is rated at 25 Watts on high power. Our sample put out over 30 Watts throughout the entire 144-147-MHz range. Low-power output is internally adjustable and we set it at 2.5 Watts. The transmitter's final stage is protected against high swr by sampling reflected power. As swr climbs, transmitter drive is reduced. I left the rig key-down with no load for over a minute, and the only thing that failed was my nerve. I figure that if anyone transmits for more than a minute without any antenna connected, it won't be Kenwood's fault if the finals blow!

Squelched receive current consumption was 0.4 A and maximum current required was 6 A in the high-power transmit mode. The rig draws about 3 mA even when the power switch is off to maintain the frequency and offset memories. Four AA nicad batteries can be installed inside the case to maintain the memories when the rig is completely disconnected from a power source. The nicads will maintain the memories for several days at a time and are automatically charged at 30 mA whenever the transceiver is on.

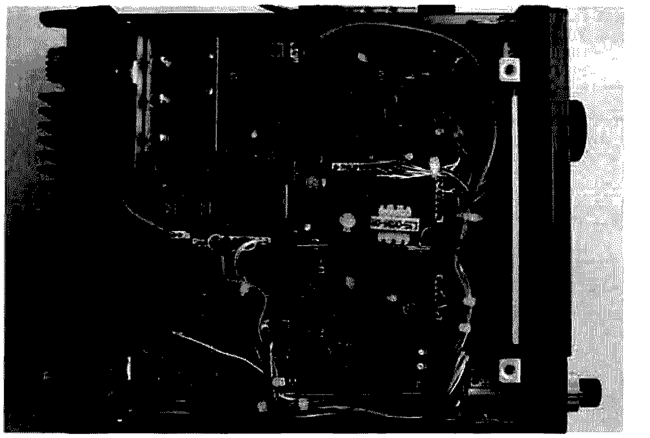
In short, the TR-7800 functions so well that its basic performance characteristics can safely be taken for granted. There is nothing temperamental about this rig, so you are free to enjoy its sophisticated bells and whistles. With no further ado, let's take a good look at those bells and whistles.

Frequency Agility

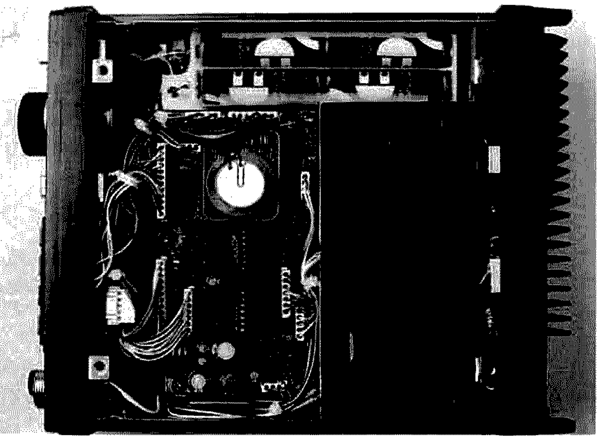
The front panel is fairly simple and the controls are easy to understand. There are several methods of selecting an operating frequency on the 7800. The first is by entering the last four digits of the desired frequency on the keypad. 146.52 MHz would be entered as 6520. If operation other than simplex is desired, the offset also is entered via the keypad.

The second method of frequency selection is to scan through the band using the up/down switches located on the microphone. The band can be scanned in 5- or 10-kHz steps, with an audio tone accompanying each step.

A third way to change frequencies is by depressing the SC button on the front panel. Don't ask me what SC means—I haven't a clue! What it *does* is automatically scan the band looking for signals. When it finds a signal, it pauses for about five seconds and then continues its scan. If you want the 7800 to come to a complete stop, you can press the transmit switch, the C button on the tone



Top view of TR-7800.



Bottom view of TR-7800.

pad, or one of the scan buttons on the microphone.

Each time you change frequencies using one of the above methods, the 7800 reverts to the simplex mode. Let's suppose that you are operating on 146.76, with the transmitter offset set to −600 kHz. If you scan up to 146.85, the rig will revert to simplex, and you'll have to punch the negative-offset button again. This would be annoying if there weren't yet a fourth method of frequency selection. This fourth method of tuning is one of the features that makes the TR-7800 a truly outstanding two-meter rig, and it deserves close examination.

There are fifteen memories available to the 7800's operator and they hold the offset as well as the frequency. Memories 1 through 13 are programmed by entering the receive frequency and a standard offset (+, −, or simplex). Memories 0 and 14 allow the receive frequency and any transmit frequency to be entered separately, so you can operate on any repeater split. Memories are selectable from the scan switches on the microphone, the SC switch on the keypad, or rotary knob on the front of the rig. The large LED readout always displays the frequency of operation, and the smaller two-digit display tells which memory has been selected.

The memories really enhance my enjoyment of two-meter activities. The ability to scan through 15 memories from the microphone makes this rig as safe in mobile use as a crystal-controlled rig, yet it offers almost unlimited frequency options. Since the rig beeps every time it steps through a frequency, you can go from repeater to repeater without even looking at the rig, much less touching it. The little keyboard also works fine, even with my large fingers, but the keyboard is a little too small to be used safely by the driver of a vehicle in motion.

The 15 memories also can be automatically scanned. When you use any rig in the band-scanning mode, it is always stopping on something that you don't want to hear. The 7800's memory scan feature allows you to be very selective about what you listen to.

More Features

I already can hear the screams of protest from all you old codgers who were weaned on big Motorola microphones. Yes, the microphone is small, but it seems to have been carefully designed. Even my massive paws handle it with ease. There is a very good reason for Kenwood's little microphone—stick-shift cars.

Ever try to jam 'er down into third with a big clunky microphone in your hand? Hard to do. You'll have no trouble shifting while holding on to the little Kenwood mike. Clearly, small microphones have arrived!

I have one complaint about the Kenwood microphone: It isn't equipped with a standard hang-up lug. It does have some kind of hook arrangement that is apparently popular in Japan, but since no mating hang-up clip is provided with the radio, you'll have to home-brew your own.

The instruction manual does a fairly good job of explaining how to connect and use the rig, and it contains a good schematic and block diagram. The manual would be a lot more effective if it made better use of the English language. I would encourage Kenwood to have their manuals proofed and edited by a native speaker of English in the future! A separate service manual is also available, but it wasn't ordered in time for review.

Compulsive input checkers will be pleased with the momentary-contact "reverse" switch, which allows one to listen on the input frequency and transmit on the output frequency of a repeater. Priority channel operation is also available. When the priority Alert switch is depressed, the 7800 scans whatever frequency is programmed in channel 0 for activity every five seconds. If there is activity, the rig beeps to let you know. You can switch over to the priority channel by pushing the priority Operate switch. Handy, eh what!

Also on the front panel is a tone switch. Activation of this switch supplies power to a user-supplied CTCSS encoder. Connections are provided inside the rig for ground, post-filter audio input, and +8 V dc. The +8 V dc is supplied only during transmit. The setup is tailor-made for a Communications Specialists encoder, but something could be home-brewed to fit in the space fairly easily.

To those of you concerned that all of this flexibility may be unreliable, relax. I remember a radio (which shall remain nameless) that came out a few years ago offering most of the features of the TR-7800. This disaster was filled with acres of mechanical switches and TTL chips. Naturally, it ran extremely hot and was unreliable. The features of this rig and the TR-7800 may be similar, but the designs are worlds apart. The 7800 uses a single microprocessor rather than discrete logic chips, and its schematic positively reeks of conservative design. It's not at all unreasonable to expect the TR-7800 to stand up to the rigors of daily use and abuse better than more conventional synthesized rigs.

There are a lot of other details that quickly endear the TR-7800 to the jaded two-meter operator. Ever scratched up a rig when you stack your two-meter rig on top of other equipment in the ham shack? Kenwood thoughtfully included four rubber feet that screw into the bottom of the rig. The slide-in mounting bracket included with the rig is one of the slickest acts in town.

Many rigs have a front-panel layout that makes them difficult to operate in the dark. The knobs and switches on the TR-7800 are carefully shaped and placed for ease of use.

The microphone would need five pins to connect the ground, audio, scanning, and PTT lines to the rig, but the TR-7800 has six pins in its mike connector, leaving a spare for the inventive ham. One possible application that immediately comes to mind is the power connection for a touchtone™ mike or an autodialer. Just connect 12 volts to the spare terminal in the mike connector and you're in business!

Conclusion

The TR-7800 is one of the most carefully thought out rigs I have ever used. Unlike many other synthesized rigs, the fancy features don't substitute for good performance. This rig's basic characteristics are beyond reproach, and I could explain

every function to another ham in less than three minutes. I rarely see a piece of equipment that doesn't have some peculiar flaw that really aggravates me. The 7800 is one of the few that doesn't. If you are about to exchange some of your hard-earned dollars for a two-meter rig, the Kenwood TR-7800 deserves your serious consideration.

KANTRONICS MINI-READER

The age of functional miniaturization is upon us. Kantronics, well established for their reputation in amateur license training tapes and accessories, has released an ultra-compact version of their famous Field Day RTTY/Morse reader.

The Mini-Reader still possesses all of the features of its larger predecessor, but has been reduced to the approximate size of a standard calculator. Measuring only 5-3/4" W × 3-5/8" H × 1-1/4"D, the Mini-Reader features 10 brilliant fluorescent characters. The display moves from right to left, Times-Square style, as the message writes across the full range of alphanumeric characters.

The primary mode is its RTTY/CW reading capability. The Mini-Reader will follow the mark signal at 60, 66, 75, and 100 wpm—any shift. A sharp audio bandpass filter rejects co-channel interference and heterodynes, assuring accurate copy. For CW reception, the Morse function will automatically track 3-80 wpm, self-adjusting to speed. Two of the characters may be used to display the Morse speed.

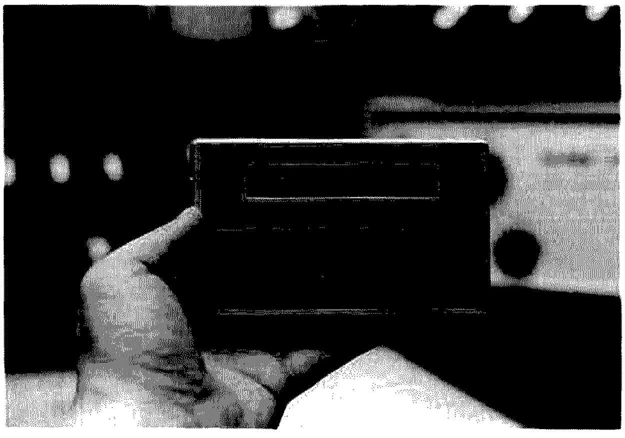
The Mini-Reader can be used as a code-practice display, assisting the user to develop a perfect fist. If your "v"s look like "e e e t" you have some work to do!

A built-in digital clock shows hours, minutes, and seconds, and may be used as a 24-hour timer as well. And for audio circuit design around the shack, the Mini-Reader can double as a frequency counter from dc to 79 kHz! Computer buffs will find the 100- and 300-baud ASCII a little fast to read, but isolated data sets can be stored and displayed.

We decided to give the Mini-Reader a thorough workout by coupling it to a Kenwood R-1000 general-coverage receiver and seeing how it would perform throughout the shortwave bands. One of the most pleasing observations was made right at the start: no RFI! The Mini-Reader switching circuitry was totally inaudible in the adjacent receiver, meaning that the days of RFI from RTTY demodulators have been relegated to the past, and they won't be missed!

In actual use, the Mini-Reader is simply affixed to an appropriate ac adapter (12 V dc at 240 mA) and plugged into the speaker or earphone jack of the receiver or transceiver. Front-panel push-button selection allows the user to select the functions of his choice.

We found the brilliant fluorescent characters even easier to read than the LEDs of the larger and more expensive Field Day model. And even happier, the price of the Mini-Reader is $150 less than the Field Day II SWL model—$314.95!



Kantronics' Mini-Reader.

We were told by Kantronics that the small size of the Mini-Reader was made possible by abandoning the pure digital circuitry of the earlier Field Day products and programming a microprocessor for control.

The Mini-Reader portends a new breed of microprocessor applications, and amateur radio will benefit from the wave of products.

For more information, contact *Kantronics, 1202 E. 23 Street, Lawrence KS 66044.* Reader Service number 479.

THE UNIVERSAL COMMUNICATIONS 2300-MHZ DOWNCONVERTER KITS

Coffee cans, snow scooters, and stop-sign-shaped PC boards in every direction. That was the general situation when a group of friends and I recently purchased a number of the 2100-MHz downconverter kits from Universal Communications. These MDS, or pay-TV, converter kits were advertised in *73*, and they seemed like an ideal way to try the rapidly growing frontier of microwave TV. We were not sure exactly what we were getting into, but the enticement of unique movies was definitely an incentive!

I won't elaborate on our phone-order difficulties, but it soon became apparent that we were in a pileup with the rest of the U.S. in trying to place our order. Fortunately, we got through on the third day of trying. The downconverter kits arrived COD three days later. Fast! The Universal Communications kit consists of the PC board, all associated board parts, a short length of hardline coax which is used for the antenna, and very good instructions/information on microwave techniques.

Construction began (immediately!) by winding three rf chokes on supplied resistors, then mounting all the components on the PC board. The board was then tack-soldered onto the back (bottom) of a one-pound coffee can, with the hardline coax routed through a small hole into a whip antenna. This arrangement provided an approximate 11-dB gain over the basic whip, and perfectly mated the PC board to the coffee can. This one particular trademark, we later learned, is what sets Universal Communications' boards apart from its competitors'.

Finally, the local oscillator's stripline was trimmed to the desired frequency range (a cutting chart was included) and a coax output cable was connected. (This single line feeds dc voltage to the converter while also feeding converter output to the TV set. Varying the voltage remote-controls downconverter tuning.) All six of us sequentially used a borrowed 0-to-16-volt power supply for checkout, and five converters worked the first time. The sixth unit was cleared soon thereafter, with simple soldering techniques being at fault. Each of us then modified existing 12-volt regulated power supplies using information supplied in the Universal Communications packet.

A day later, we were into studying microwave systems, components, and gain-improving techniques for fringe-area setups. Several nearby residents mysteriously lost their shiny, new garbage can lids around this time, then we found a local source of "snow scooters" and gain flourished. The "snow scooter," or "snow coaster," is an approximately three-foot, parabolicly-shaped dish which, when fitted with struts to support the coffee-can setup, provides approximately 18 dB of gain—and relatively good picture reception compared to the basic coffee-can or garbage-can-lid setup. Our personal observations revealed that previous pictures with sustantial snow were improved to almost snow-free quality, and each additional improvement of approximately one dB made further substantially noticeable improvements.

Gain improvement at these microwave frequencies, however, is slow in happening: A larger dish helps; a higher-gain rf amplifier also helps. (Universal Communications also sells these transistors for $15, and they are definitely worth it, unless one can wrangle a very high-gain/low-noise 50- or 75-dollar equivalent.) We also found that adding extra lengths of parallel conductors to the Universal Communications PC board capacitors and using low-noise microwave diodes provid-

FUN!

Shortwave listening? Why not! While SWLing may not be a part of amateur radio, there's no denying the very close relationship between the two hobbies. While CBing may have usurped SWLing as the main gateway to ham radio, thousands still get their first taste of hobby radio by listening to the international shortwave giants on a portable radio. In any event, it's a well-known fact that many hams are closet SWLs. As a matter of fact, more than one prominent DXer has been known to guard his top shortwave QSLs as jealously as many of his most-prized ham pasteboards.

So, whether the closest you get to shortwave listening is fighting the BBC World Service on 40, or if you regularly scan 41, 19, and 13 meters more often then 40, 20, and 15, the world of SWLing is something we should all know a little more about.

ELEMENT 2—MATCHING

While not "shortwave" in a strict technical sense, listening to distant broadcast-band stations is an activity stretching back over 60 years. Here, match the call of the station to its QTH. All stations listed run 50 kW and operate 24 hours a day. All have been licensed since the earliest days of broadcasting.

Column A	Column B
1) KDKA	A) Atlanta GA
2) WOR	B) Nashville TN
3) WWL	C) Portland OR
4) KGO	D) Denver CO

NEW PRODUCTS

The MFJ-494 Keyboard Keyer.

NEW MFJ KEYBOARD

The all-new MFJ Keyboard Keyer, model MFJ-494, is a full-fledged keyboard that sends CW, Baudot, and ASCII, with 50-character text buffer, 30-character programmable message memory, 4 automatic messages, 2 random-code practice modes, speed and buffer metering, back-space delete function, and buffer memory hold function; just plug it in your paddle and it's a full-function keyer.

Simple one- or two-keystroke combinations execute all commands.

The 50-character text buffer can be filled prior to sending (preprogrammed) or it can be filled at any given speed if you type faster than the code is being sent. When the buffer approaches full, the sidetone pitch changes and a red LED comes on to warn you to slow down to prevent buffer overflow.

The 30 characters of programmable memory provide enough memory for contester or DXer when used in conjunction with the 4 automatic messages contained in the keyboard. The 4 automatic messages let you call CQ, CQ TEST, QRZ, and ID without using all of your programmable memory.

Two code-practice modes let you work on your code proficiency. The first mode is pure random code with random-length groups. The second mode is 5-letter groups with 8 separate repeatable lists (with answers) to check your learning progress. Space between letters may be expanded to improve recognition in both modes, and in the second mode you may select alphabet only or alphanumeric plus punctuation.

A meter tells you your sending speed (speed may be set before sending begins), or you may just push a button and the meter tells you how much buffer you have used and how much you have left.

The model 494 will forgive you for making errors while the buffer is in use. To correct an error, simply backspace over the error and resume typing.

A buffer memory-hold function lets you hold the buffer memory or pause without losing the buffer. You can send with paddles while the buffer is being held; this makes possible operating full break-in.

A push-button lets you key your rig continously for tuning and testing, and a 2-keystroke combination gives you continuous dits for tuning and testing that extends the life of your finals.

The keyboard is also a full-function keyer. Just plug in your

OSCAR ORBITS

Courtesy of AMSAT

The OSCAR satellites are subject to atmospheric drag, of course, and the present period of intense solar activity has accentuated the problem. During this period, our sun has been expelling huge numbers of charged particles, some of which find their way into the Earth's upper atmosphere, increasing the density (and thus the drag) there. It is through this region that the OSCARs must pass. OSCAR 8, in a lower orbit than OSCAR 7, is the more seriously affected of the two.

If the drag factor is not considered when OSCAR calculations are performed, long-range orbital projections will be in error. For example, by the end of 1979, OSCAR 8 was more than 20 minutes ahead of some published schedules. The nature of orbital mechanics is such that extra drag on a satellite causes it to move into a lower orbit, resulting in a shorter orbital period. Thus, the satellite arrives above a given Earthbound location earlier than predicted.

Using data supplied to us by Dr. Thomas A. Clark W3IWI of AMSAT, the equatorial crossing tables shown here were generated with the aid of a TRS-80™ microcomputer. The tables take into account the effects of atmospheric drag and should be in error by a few seconds at most.

The listed data tells you the time and place that OSCAR 7 and OSCAR 8 cross the equator in an ascending orbit for the first time each day. To calculate successive OSCAR 7 orbits, make a list of the first orbit number and the next twelve orbits for that day. List the time of the first orbit. Each successive orbit is 115 minutes later (two hours less five minutes). The chart gives the longitude of the day's first ascending (northbound) equatorial crossing. Add 29° for each succeeding orbit. When OSCAR is ascending on the other side of the world from you, it will descend over you. To find the equatorial descending longitude, subtract 166° from the ascending longitude. To find the time OSCAR 7 passes the North Pole, add 29 minutes to the time it passes the equator. You should be able to hear OSCAR 7 when it is within 45 degrees of you. The easiest way to determine if OSCAR is above the horizon (and thus within range) at your location is to take a globe and draw a circle with a radius of 2450 miles (4000 kilometers) from your QTH. If OSCAR passes above that circle, you should be able to hear it. If it passes right overhead, you should hear it for about 24 minutes total. OSCAR 7 will pass an imaginary line drawn from San Francisco to Norfolk about 12 minutes after passing the equator. Add about a minute for each 200 miles that you live north of this line. If OSCAR passes 15° east or west of you, add another minute; at 30°, three minutes; at 45°, ten minutes. Mode A: 145.85-.95 MHz uplink, 29.4-29.5 MHz downlink, beacon at 29.502 MHz. Mode B: 432.125-.175 MHz uplink, 145.975-.925 MHz downlink, beacon at 145.972 MHz.

At press time, OSCAR 7 was scheduled to be in Mode A on odd numbered days of the year and in Mode B on even numbered days. Monday is QRP day on OSCAR 7, while Wednesdays are set aside for experiments and are not available for use.

OSCAR 8 calculations are similar to those for OSCAR 7, with some important exceptions. Instead of making 13 orbits each day, OSCAR 8 makes 14 orbits during each 24-hour period. The orbital period of OSCAR 8 is therefore somewhat shorter: 103 minutes.

To calculate successive OSCAR 8 orbits, make a list of the first orbit number (from the OSCAR 8 chart) and the next thirteen orbits for that day. List the time of the first orbit. Each successive orbit is then 103 minutes later. The chart gives the longitude of the day's first ascending equatorial crossing. Add 26° for each succeeding orbit. To find the time OSCAR 8 passes the North Pole, add 26 minutes to the time it crosses the equator. OSCAR 8 will cross the imaginary San Francisco-to-Norfolk line about 11 minutes after crossing the equator. Mode A: 145.85-.95 MHz uplink, 29.4-29.50 MHz downlink, beacon at 29.40 MHz. Mode J: 145.90-146.00 MHz uplink, 435.20-435.10 MHz downlink, beacon on 435.090 MHz.

OSCAR 8 is in Mode A on Mondays and Thursdays, Mode J on Saturdays and Sundays, and both modes simultaneously on Tuesdays and Fridays. As with OSCAR 7, Wednesdays are reserved for experiments.

AWARDS

from page 12

be a mobile station yourself, giving out contacts in all the counties of any one state. As you can see, there are 50 state awards for each category listed above. A potential of 150 individual awards if you mastered them all! Whew! You may work any band or mode.

As with the other awards, do not send QSL cards! Have your contacts verified by at least two amateurs and forward this list and a $1.00 award fee to Ray Teeter N2RT, RD 2, Canaan Heights, Locke NY 13092.

Full details of the *73* Awards Program can be found in the August and September, 1980, issues of this magazine. Why not become part of the fastest growing awards program around!

BONANZA AWARD

The Bonanza award is probably the most demanding of all the awards being offered by Ray.

To qualify, applicants must work the same mobile in the various counties of a single state. There are three categories in which to apply. Class A—working the same mobile in all counties of a single state; Class B—working the same mobile in ⅔ of the counties within a single state; and Class C—working the same mobile in at least ⅓ of the counties of a single state.

Both the applicant and the mobile contact will get awards for their efforts. To apply, prepare your list of contact dates and times, band and mode of operation, county and state of operation, and last and most important, the mobile contacted in each case.

Have your list of contacts verified by at least two amateurs or a local radio club secretary. Send a $1.00 award fee and your application to: Ray Teeter N2RT, RD 2, Canaan Heights, Locke NY 13092.

UNION COUNTY AWARD

Here is an historical award being offered by Ray which requires the applicant to work Union counties of the United States.

Offered in three award categories, applicants must, for Class A, work 18 Union counties of the USA; for Class B, work 12 Union countries; and for Class C, work at least 6 Union counties of the USA.

Send your list of verified contacts along with a $1.00 award fee to Ray Teeter N2RT, RD 2, Canaan Heights, Locke NY 13092.

ARMSTRONG PIONEER AWARD

The Major Armstrong Memorial Amateur Radio Club has instituted the Armstrong Pioneer Award, an honor to be bestowed annually on the amateur who has, in the opinion of the voting members, done outstanding service for an amateur community.

Any amateur operator or group of amateurs may nominate a ham whom they feel meets the criteria listed below. Nominations opened November, 1979, and will be accepted for as long as the award program exists. Members of the Major Armstrong Memorial ARC will review each year's nominations every spring, determining by vote the amateur who, in the spirit of Major Edwin H. Armstrong, inventor of Frequency Modulation, has contributed the most to amateur radio through pioneering efforts.

The following criteria should be observed when considering an amateur for nomination: (1) the nominee should be a licensed amateur or group of amateurs; (2) the nominee should have made a significant contribution to ham radio by experimentation and development in new or little-used bands or modes (examples: development of equipment for SSTV, OSCAR, RTTY, EME; revival of neglected modes like facsimile; technical developments that help populate little-used bands, etc.); or (3) the nominee should have made a significant contribution to ham radio by promoting the use of such bands or modes (examples: efforts to keep 10 meters during sunspot minima via nets, clubs, beacons, etc.; efforts to increase activity on 1296 MHz and microwave bands; efforts to keep AM or other obsolete modes alive via nets, contests, etc.; efforts to promote the concept of amateur radio in countries where it is not permitted, etc.).

The examples are only that; the committee hopes the ham fraternity will respond with news of any kind of amateur radio pioneering.

Talk about this award nomination at your next club meeting. Send your statement about the nominee you select to: Major Armstrong Memorial Amateur Radio Club, Inc., PO Box 1234, Englewood Cliffs NJ 07632.

THE REVEREND JOHN FLYNN MEMORIAL AWARD

This award has been instigated by the Alice Springs Community College Radio Club of Australia. It was founded in memory of Reverend John Flynn, who pioneered the Australian Inland Mission, the Royal Flying Doc-

THE SIX-METER READER REACTION DEPARTMENT:

Though it's taken some time, we are now really getting input and ideas concerning amateur radio's repopulation of the six-meter band. One of the most interesting letters received came from Lew Collins W1GXT, and it reads:

I read your September, 1980, column, Looking West, with much interest since I have been working on the development of a six-meter bandplan for a number of years. In addition, I have been a user of the band during all those years, and thus feel I am qualified to offer some insights into the six-meter problem that are not available to a passive observer such as you. I am hopeful that the comments that I am offering, which may on the surface sound a bit negative, will be received by you in the constructive spirit in which they are intended.

In my opinion, *three* factors led to the demise of six meters as you remember it: 1) The growth of two-meter FM/repeater operation, 2) The ever-present TVI problem on six, and 3) The decrease in solar activity. Probably item 1), as correctly observed in your article, was the major factor. I claim that the bulk of six-meter activity was of the low-power, rag-chewing local nature that you remember, with a little DX sprinkled in for excitement. The six-meter station with a pair of 4-400s and six-over-six yagis was the exception, rather than the rule.

TVI has always been a serious problem for the six-meter operator, particularly in those areas with channel 2 (Boston, New York, Los Angeles, etc.). The consumer electronic equipment of the 70s not only exists in unprecedented quantity, but the interference rejection properties in general are poorer as manufacturers strive to remain competitive. Many six-meter operators who went QRT because of TVI discovered they could have as good or better local communication without the TVI hassles by getting on the local two-meter repeater. Unknown to you, the diehards with the big rigs and big antennas sat quietly by waiting for the DX openings of 1979-80. Just read a few issues of K5ZMS's newsletter if you don't believe me!

I must take exception with your statement that none of the existing input-output spacings is workable. (Otherwise, why would so many different standards flourish?) I could list numerous counter examples to your claim, but perhaps the most striking is the repeater located on the WCAU-TV tower in Philadelphia which uses 120-kHz input-output separation! This repeater has wide-area coverage and hundreds of users.

The basic parameter in designing a duplex transmission system, such as an amateur repeater, is *not* the number of kilohertz separation between the transmitter and receiver frequencies, but rather the percentage separation. Thus, if we are to adopt 220-MHz standards for use on six meters, the optimum input-output separation is: $1.6/223.5 = 0.0072$, which works out to be 380 kHz at 53 MHz. Interesting enough, North Shore RF Technology, who pioneered the notch-type duplexer for the amateur market, produced a six-meter duplexer for 400-kHz spacing.

The 220-kHz separation used in southern California and the 200-kHz value used in eastern New England were both derived the same way, but starting with the now universal 600-kHz separation used on two meters. $0.600/147.0 = 0.0041$, which gives 216 kHz at 53 MHz.

There is another side to this input-output separation issue which you totally neglected in your article. While it is true that the greater the input-output separation, the easier it is to make a repeater work, that is not necessarily true for the *system* consisting of *one* repeater plus a *number* of mobile users. Specifically, many of the amateurs who operate six-meter FM use high-quality transceivers which were originally manufactured for the land-mobile market by Motorola, General Electric, RCA, etc. These are not the old vacuum-tube boat anchors you remember from your early days of amateur FM, but are frequently solid-state or hybrid designs offering the state-of-the-art in mobile transceiver performance.

In order to produce a quality transceiver, the front-end as well as the transmitter exciter stages are fairly narrowband to minimize spurious output and responses. Consequently, there is a definite upper limit imposed upon a repeater's input-output separation by the user's radio, assuming that the user desires to have the capability of simplex as well as repeater operation. (It is my observation that most six-meter FMers desire to maintain a simplex capability. In fact, one of the major advantages of six over two is that the simplex working range is greater. That is why I originally got on six meters.)

"...I believe you do not take the amateur radio control enthusiasts seriously enough...they will not QSY without a fight. I would like to see you propose a plan based on FCC regulations as *they now exist*...so that it could be put into effect sooner rather than later."

I must also point out that you have made an error in using and interpreting Carson's Rule. Carson's Rule *does not* say that the bandwidth of an FM signal is infinite, although an *exact* mathematical analysis of an FM signal does lead to that conclusion. What Carson's Rule *does* say is that an FM signal does not have *appreciable* sideband energy outside of the band $B = 2f + 2W$. All Carson's Rule says is that an FM signal occupies more bandwidth than does AM; practically speaking, both have finite bandwidth.

The issue of whether the repeater or user transmitter should be closer to TV channel 2 is a bit more complex than you have indicated. Although I happen to agree with your position on this matter, others have argued loud and long for the other way around.

Unfortunately, I believe you do not take the amateur radio control enthusiasts seriously enough, and if you have not heard from them by now, it is merely because they have not read your proposal. In my experience, they view 53.1, 53.2, 53.3, 53.4, and 53.5 MHz as their private domain, and they will not QSY without a fight. Space does not permit going into this complex issue here.

There have been numerous attempts over the past ten years to move the national simplex channel from 52.525 MHz to something else, such as 52.520, with no success. There are hundreds (maybe thousands) of six-meter FMers in the less densely populated areas who operate 52.525 MHz exclusively, and, consequently, there is a great deal of resistance to change. I believe that any realistic bandplan will have to accommodate this long-established frequency, even if it doesn't make sense logically.

Your proposed use of 50.00 to 50.25 MHz is slightly at variance with accepted practice there, and needs slight revision. SMIRK, the Central States VHF Society, and other well-known VHF DX groups should be consulted on this point.

In summary, I am in complete support of your appeal for a national six-meter bandplan. However, I believe your proposal has some major flaws which must be corrected if it is to gain acceptance. Otherwise, we will just progress from having N different six-meter plans to having N + 1 such plans. In addition, I would like to see you propose a plan based on the FCC regulations as *they now exist*, so that it could be put into effect sooner rather than later.

Keep up the good work.

Best regards,
Lewis D. Collins W1GXT

As you can see, Lew spent quite a bit of time in preparing his commentary. There is much with which I agree, and points on which I disagree. The important thing is that he took the time to write. Next month, I'll answer Lew's letter. In the meantime, keep your thinking caps on.

The History of Ham Radio
—part XIII

Reprinted from QCC News, a publication of the Chicago Area Chapter of the QCWA.

On the lighter side of amateur radio, during the long winter nights, there evolved within the fraternity a new phase of activity. It had its inception in the many curious, humorous, and indescribable stories under the pen name of

The Old Man

who now, through the lapse of time, has become a hallowed legend. The legend is now permanently memorialized in the Wouff Hong Story.

According to research, the ever-present references to the fabulous wouff hong came about like this: In the days when amateur radio was in swaddling clothes, way back in about 1914, there emerged a personality known as the Old Man.

As reality would have it, this individual was, as all amateurs were and are to this day, afflicted with the sad but ever-present problem of raucous disturbances, be they man-made, nature-made, or even fabricated right within the shack of the beholder. This perpetual problem was known in the days of yore as "Rotten QRM." But to go on with the research.

Plagued in the very early days of wireless communication with such interference, driving sane but determined listeners (wishing to remain that way) to distraction, especially when the headphones were securely clamped over both ears, listening intently for what the Morse dots and dashes were meant to convey, there emerged the following effusive but clear and loud verbiage into print [the Old Man exclaiming]:

"Fellows, [all excited and boiling over] fellows, this QRM business is getting my nanny—here it is midnight—I have smoked myself into a state of funk—the floor is covered with burnt matches—I am losing a perfectly good temper—there is no sign this will not continue all night long . . . How long do the radio bugs sit up at night anyway?—What are we going to do about

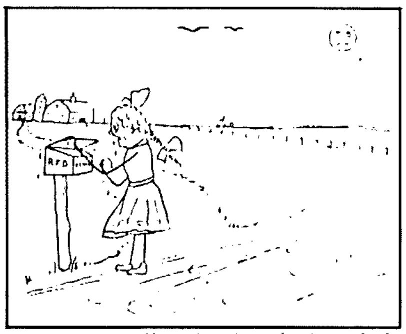
8 QST January, 1917

Rotten QRM

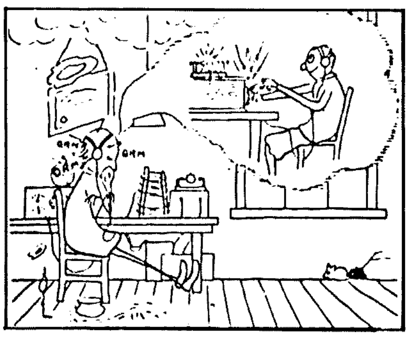
By "The Old Man."

Say, fellows, here's the old man again This time he's all excited and boiling over. In fact he's so wild about some "Rotten" subject that he has fallen back to some queer dialect and shouts about "wouff hong's", "rettysnitches", and some disorder known to the trade as "ugerumf". What do all these mean? Better read the article and see. —Editor.

Smoked himself into a state of funk.



Poor girl in Ill. who hasn't heard from her fellow in 24 hours.



Rubber band—Commercial tone.

this business?—When we heard some commercial station say QRM we had to look it up on the chart to see what it meant. . . Later we began talking to the fellow over on the other side of town, and then was born our amateur QRM.

"But when we have a fellow who has not written to his girl for a full twenty-four hours, and who positively must get the message to her over in Illinois, it becomes a serious matter to have someone else getting gay with the ether, especially when the latter has no conception of the existence of the word 'brevity.' The trouble is, the young squirts don't stop to think. Willy with his sputtering spark coil discharge sends out this hogwash—now listen to this . . .

" 'Yes yes jst wyd glucky wait a mt muddy wouff hong bliftsky monkey motor.' We assume from this message that Glucky is being asked to wait a minute while Bliftsky seeks a wouff hong with which to wallop a monkey the next time the latter faces towards the motor. I do not think I know just exactly what a wouff hong is. Probably some piece of apparatus used in the southern states to beat monkeys with.

"It is this form of uninteresting 'conversation' which clutters up the air with QRM. Of what moment is it to the rest of the world that this fellow Bliftsky is going to smear somebody's monkey with a wouff hong? When anybody relapses into such a mental slop as to want to operate with a thing named a wouff hong, he ought to keep his trouble to himself and not compel all of us respectable amateurs to listen to his drool. To slave and slobber a lot of foolish twaddle like this when that poor girl in Illinois has not had a letter since yesterday is plain wicked.

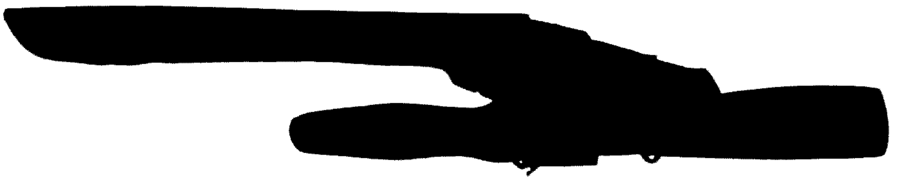
"Or just cast a lingering look at this:

" 'Biirgrmph bru rotary ge ge ugerumf om with my set rettysnitch spitty tone hit in potimus?' Now what do you suppose the poor gink was trying to say when he unreeled that? You have to guess a lot in wireless, and how would you guess this? Something is wrong with this fellow's biirgrmph, his rotary also has a bad case of the ugerumf and somebody around the place must have spit on his rettysnitch, because his tone was so rotten it hit him on his potimus. Sounds bad to me. Why will some people send such personal matter by wireless when the whole country can overhear? It isn't decent, and it makes the QRM more rotten than ever, and just think of the way it makes a perfectly good logbook appear.

"I spent the better part of an hour trying to make out what ailed the poor fellow's biirgrmph, but had to give it up. What we ought to do is to organize an Anti-QRM Association. Then let us elect for Chairman the worst plug-ugly we can find in these U.S.A. Then let us chip in a little money and hire a clerk with a bad disposition who will write letters threatening the life of everybody whom the members report as causing needless QRM. Let us rise, fellow bugs—down with the fellow with the scratchy spark coil—down with the fellow, the unspeakable skunk who calls somebody and sends a long relay message repeating each word three times when the station to which he is sending is sending one thing at a time himself.

"There, by heck, I have that stuff off my back and chest. Now you over there in Illinois, get this call—let everybody stand back from now on—I'm tired and sleepy and cross—and I don't care who I QRM, until I get that pin cleared off. . ."

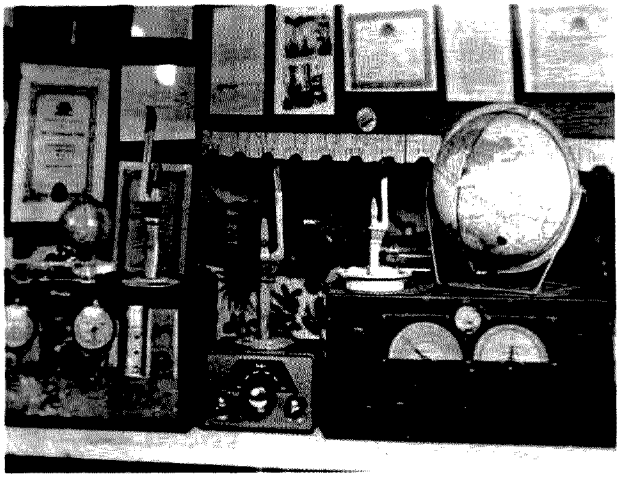
That was the way the Wouff Hong was brought into being, and it will continue to dominate the cold and blustery nights at ham gatherings to perpetuity—Believe it or not!! ■



THE ORIGINAL WOUFF HONG.

THE OLD MAN

WELL! WELL! WELL! LOOK WHO'S HERE. A picture of THE OLD MAN. It came in the mail, just like all his stories.



Three Wouff Hongs decorate a ham shack.

Build a Frequency Counter—That TALKS!

—state-of-the-art for blind hams

The availability of low-cost speech synthesizer technology has opened many doors for the sightless amateur. The introduction of a "talking calculator" several years ago was the first and most affordable example of synthesized speech instruments which are useful to the visually-handicapped amateur.

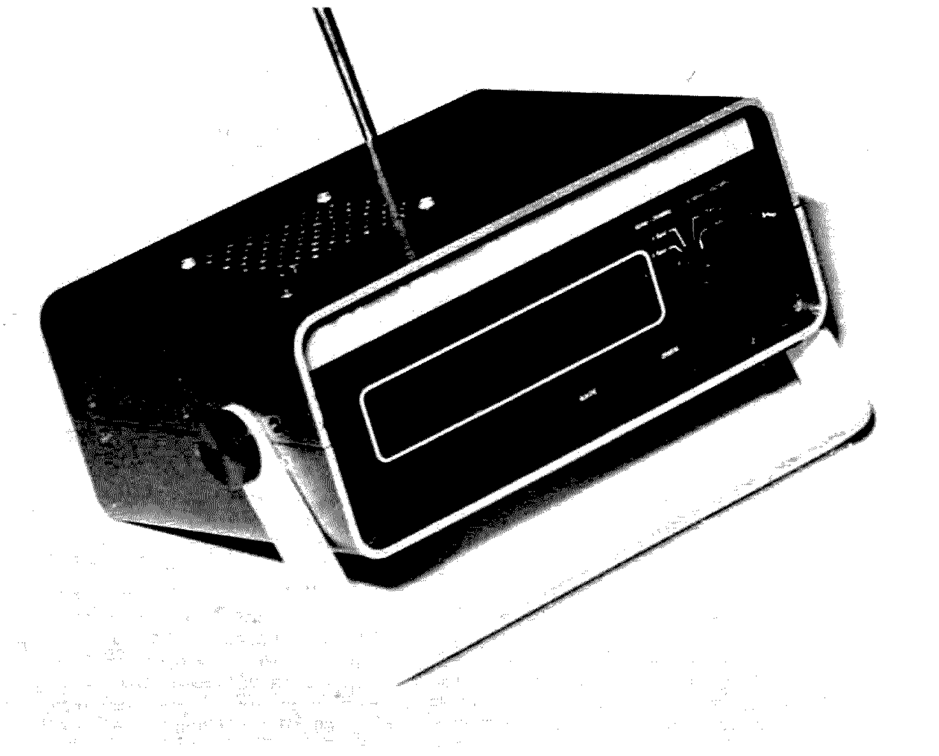

Photo A. There is little evidence that this DSI Model C-700 frequency counter has a voice of its own. The push-button in the left-hand corner of the cabinet top triggers an 8-digit readout. Volume and audio-visual controls are on rear panel.

Through the courtesy of the manufacturer, Telesensory Systems, Inc., of Palo Alto, California, the heart (or, more appropriately, the voicebox) of the Speech Plus Calculator recently has been made available at a reasonable price. Since that time, several efforts have been made to interface this module to available amateur equipment. Most have been relatively complicated, requiring from 10 to 30 or more IC packages.

Thanks to the forethought of the designers, a simple and very easy to duplicate interface is possible, eliminating a major barrier to more widespread use of synthesized speech in digital equipment. The model C-700 frequency counter, manufactured by DSI Instruments of San Diego, California, is based upon the LSI Computer Systems LS 7031 counter IC, which is ideal for this application. Other test equipment may be connected to the synthesizer module in a similar manner. The only

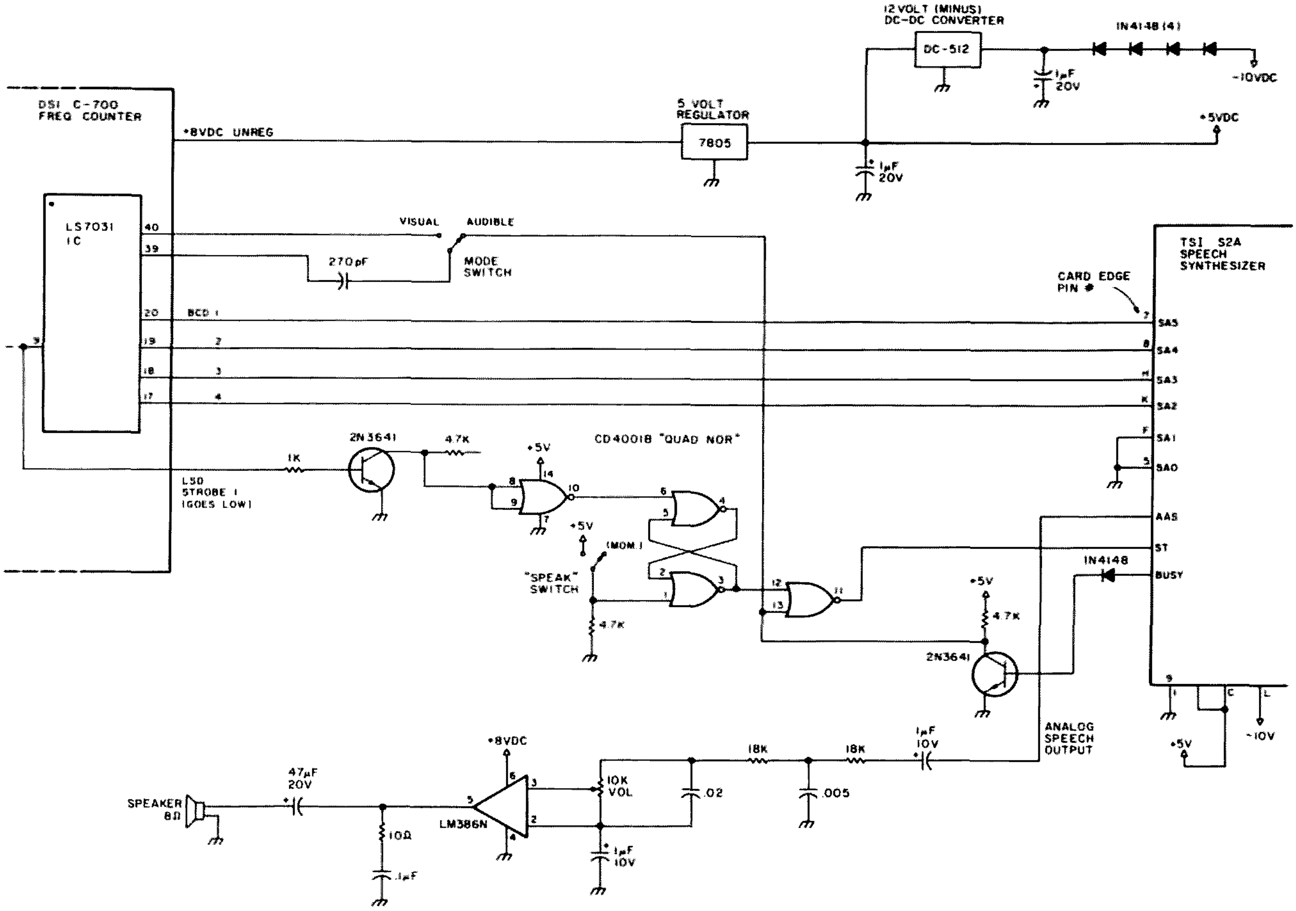

Fig. 1. Talking Counter schematic.

requirement is access to the display multiplexer clock circuit, as will be explained later.

The Telesensory Systems (TSI) model S2A synthesizer module was selected for the Talking Counter. This module provides all ten numerals, plus a few common math and calculator-type words in its 24-word vocabulary (see Table 1). Larger, 64-word models are available, but their higher cost and added features weren't necessary for this application.

The TSI module is easily interfaced to TTL levels using a negative bias voltage which can be easily obtained by use of a small and inexpensive dc/dc converter in systems where a source of minus voltage is not available. In a year of playing with the synthesizer module, it has proven to be quite rugged and resistant to handling and breadboard accidents. So, perish the thought of ruining a $95 board!

TSI provides application notes which offer suggestions on appropriate filtering to eliminate excessive noise and hiss from the digitized audio signal. Since a non-standard audio amplifier was used in the prototype, some changes were made. The filter shown on the schematic is recommended by TSI for the common LM386 audio amplifier IC. Some conditioning is required to make the "Busy" line TTL compatible, but all inputs can be driven directly by TTL or CMOS circuitry.

To make speech, the appropriate BCD code is set up on the S2A input and the Start line is pulsed. Speech will begin on the negative edge of the strobe signal. Also, once speech has begun, the S2A will signal this by means of the Busy line. This pin will go active when the module is "talking," returning to the off state when finished. By simple gating, it is easy to make the speech board say complete words, without "stuttering" or interrupting itself.

In order to make a typical digital display "speak," it will be necessary to start at the left-hand side and step across the display from left to right, "saying" each digit along the way. Some designs choose to latch every digit or to try to get in sync while the display is operating. Neither approach is easy, and neither is necessary, because of what started out as a shortcut for the chip designer.

With a limited number of pins on an IC, it is impractical to dedicate an individual set of digit and segment pins to each digit in a multidigit display. So, nearly every display designer relies on multiplexed displays, where four common BCD data lines are shared by all digits. Then, each individual digit is turned-on or "strobed" when its data is valid. Since the digit strobes occur pretty often (usually every millisecond or so), persistence of vision makes it appear that each display is lit up all the time. The multiplexing clock runs fast, to avoid flicker, but isn't critical.

It is so non-critical that the chip designer often relies on a simple RC time delay to make the oscillator

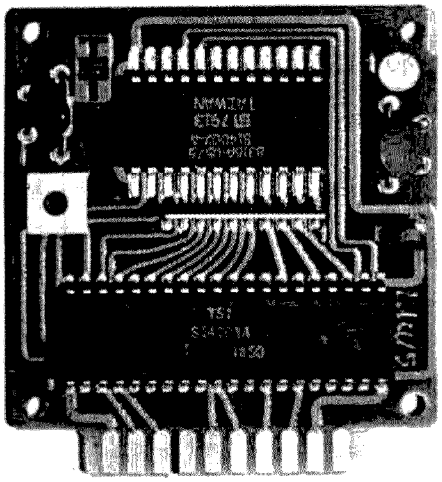

Photo B. The S2A speech synthesizer board from Telesensory Systems, Inc. The large IC is the CRC micro-controller. The entire 24-word vocabulary is contained in the smaller 16K ROM. All connections are by way of the double-sided card edge connector (10 pins per side).

work. But, recognizing potential need for a specific multiplex rate, the designers at LSI allowed provision for user control of the multiplex rate on the LSI 7031 counter IC. By removing the capacitor normally used for the on-board clock, it is possible to control the scan oscillator in the chip.

A Scan Reset pin is provided, which advances the scan counter in the IC to the left-hand digit. This pin could be used to reset the scan counter, but it wasn't found to be necessary. However, by applying a pulse to pin 39, the scan input, the counter IC would step across the display, left to right, just as was desired!

The actual interface is very simple, consisting of just one 40-cent CMOS gate package in addition to power supply and audio amplifier parts (see Fig. 1). The speech readout is initiated by pressing the Speak switch, which sets an R-S flip-flop and allows the strobe line to go true. There will be a short pulse when the Busy line signals the end of the word, and this acts as a clock pulse to move the scan counter in the counter IC on to the next digit.

The process continues until the last digit is spoken, when the positive edge from the eighth counter digit serves to reset the flip-flop and terminate the speech. The only connections required to the counter are the four BCD data lines, the addition of a switch to the scan input to select visual or audible display, and a wire to the eighth digit strobe. Because of the ease of interfacing this circuit, it should be easily duplicated, and

Table 1. The "voice" of the S2A is that of Dr. Forrest Mozer, inventor of the speech-generation algorithm used by the LSI controller. The speech synthesizer is a static-sensitive device and normal MOS handling precautions should be observed.

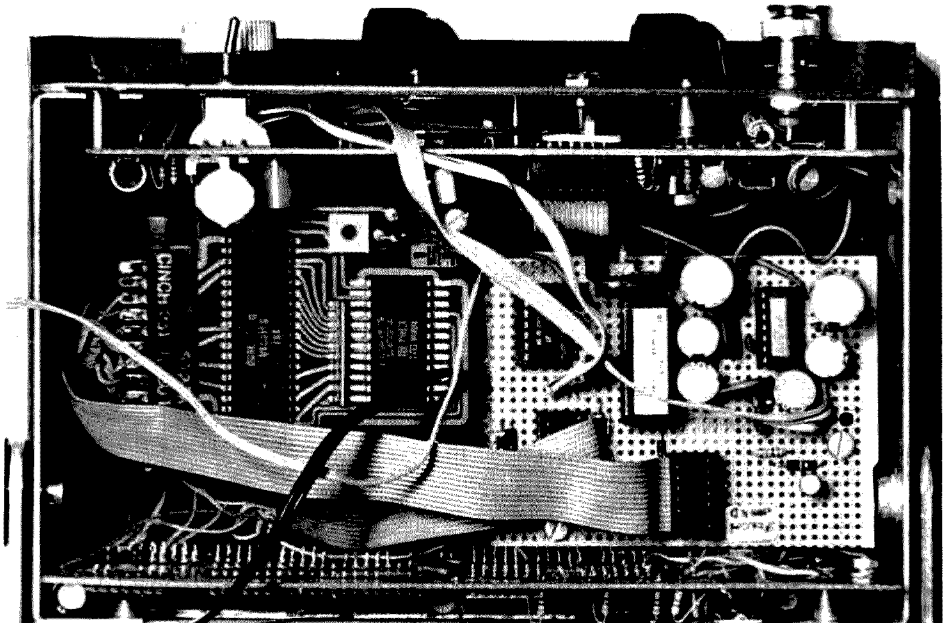

Photo C. Inside the counter. The speech board is visible on the left and the power supply and amplifier-interface circuit board are on the right. Note DIP-plug connections to counter mainframe. Large module at right is dc/dc converter that generates −10 volts for synthesizer. Speaker is mounted to top cover.

possibly adaptable to other equipment.

A glance at the databook reveals that several popular A/D chips commonly used in digital multimeters and some clock ICs provide similar access to the multiplex scan clock. In fact, just about any device with a multiplexed display would be a good candidate for an artificial voice implant!

Construction is non-critical, and inside the metal DSI case, no problems with rf have been encountered. Removal of the lead-acid battery pack provided plenty of space for the TSI module and the interface/amplifier board. Connections are merely tack-soldered to the counter PC board, with plug-in DIP cables to the added board. Power can easily be robbed from the counter, with a 7805 regulator and the dc/dc converter used to power the synthesizer. Minus 10 volts is needed, but since a minus 12-volt converter was available, a few diodes were used to drop the voltage a bit. Some experimentation may be needed to fine tune the audio filtering for a specific amplifier-speaker configuration. Use of a good-sized speaker helps intelligibility, as does tweaking the clock pot on the S2A board.

Further enhancements could include leading-zero suppression and automatic "point" insertion for locating the decimal. But the added complexity and circuitry required may offset any possible advantage. After a few minutes use, one becomes quite adept at reading frequencies, and frills aren't missed while enjoying the "Cylon-like" sound of the counter!

One idea worth exploring, though, is to separate the "talker" by itself, making it easier to use one synthesizer on several instruments. But in a few years, advances in speech technology will decrease costs enough that one won't mind having a dedicated voicebox in every instrument. In fact, applications for artificial-speech devices are by no means limited to aids for the handicapped.

It is quite handy to check frequency without crawling underneath a dash-mounted radio, or to be able to get a frequency report right from the repeater's mouth. At least one repeater uses the TSI modules for ID and telemetry, and more applications for this versatile and affordable module just await the experimenter's imagination!

A Talking Counter is a valuable tool for the blind ham or technician. The marriage of the DSI counter and the TSI synthesizer is a natural and, hopefully, will open the door for more useful and inexpensive applications of modern artificial speech synthesis techniques. ■

In the Stack

—R/Cers, don't be grounded by control channel congestion! Put your ship on six!

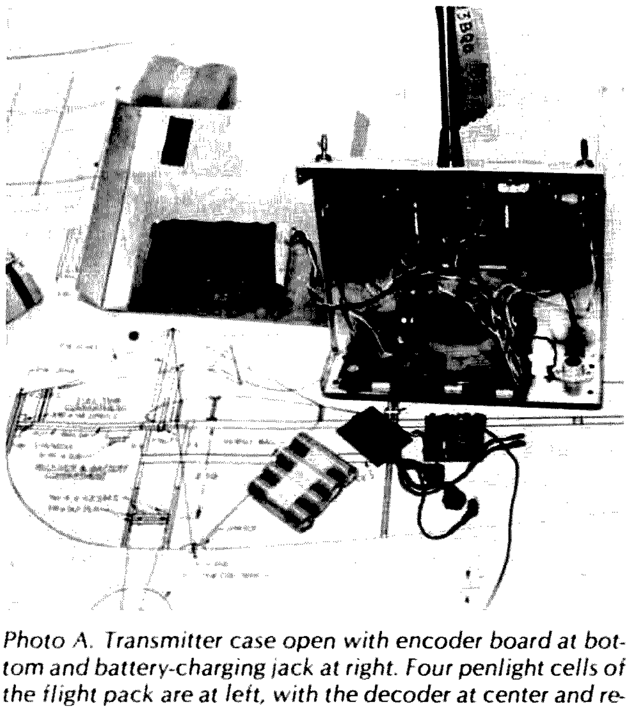

Photo A. Transmitter case open with encoder board at bottom and battery-charging jack at right. Four penlight cells of the flight pack are at left, with the decoder at center and receiver at right. Eight-cell transmitter pack at upper left is held to the rear panel of the case with silicone rubber. Switches at the top of the transmitter case are sixth- and seventh-channel controls. They are for dropping bombs or parachutes, operating retractable landing gear, or anything that does not need to be proportionally controlled.

The model airplane contest is under way. Over a hundred pilots and their planes are gathered in the open meadow. At the pilots' briefing, your radio control frequency is announced as being the most crowded. This means that instead of selecting the time to fly when conditions are best, you must wait to be called to the flight line to fly. Only one R/C rig can be in operation at one time, or the resulting interference will cause the model to crash.

With ten or more pilots on the same frequency as you, the rotation of the roster means a long wait between flights, and being hurried when your name is called. The additional pressure of being on a crowded frequency on top of the usual "first flight nerves" is unsettling and will not help your scores. There ought to be a better way!

For hams, there is a better way. While there are only seven channels for R/C operation in the 72-MHz band for non-hams, there are five channels from 50.100 to 50.500 MHz in the six-meter band. While these are not exclusively for R/C operation, the ARRL and most ham groups throughout the world have agreed to reserve them for radio-control purposes. At a typical contest, there may be four or five hams flying, so the crowding on any particular frequency will be very light. Now, instead of having to wait to be called up to fly, you can pick the best time and choose the right conditions, not being bound by the frequency roster.

While there are several factory-built radios on the six-meter band, most hams prefer to put together a kit. The best known of these is from Heathkit®, and this brand is always well represented at the flying field.

Ace R/C, Inc., of Higginsville, Missouri, and Royal Electronics of Denver, Colorado, also make radio kits for the six-meter band. While all three firms offer some flexibility in the choice of styles in components, Ace seemed to have the widest variety of gear at lower prices than the others.

Since most R/C rigs operate on the same basic principle, the choice of gear comes down to the specific use to which the rig will be put. For small three-foot-wingspan models flown in small spaces such as school yards, the smallest and lightest rig is best. For quarter-scale monsters weighing twenty-five pounds and spanning nine or ten feet, the size and weight of the rig don't mean a thing. It takes very powerful servos powered by large capacity batteries to move the ailerons or elevator on these biggies.

The radio in the photos is the seven-channel kit from Ace R/C, with the transmitter housed in a Royal Electronics case. In operation, the rig controls the plane like this: The pilot's thumbs rest on the two control sticks on the transmitter. Each stick moves both forward and back as well as from side to side. The right stick controls the ailerons (left/right) and the elevator (forward/back). The left stick controls the rudder (left/right) and the motor speed (forward/back). The remaining controls are operated from switches and levers on the front and top of the case—bomb-drop, landing-gear retract, and wing flaps.

Each stick moves a potentiometer which varies the width of a digital pulse that becomes part of a pulse train. The pulse train has a clock pulse and seven data pulses, one for each control. The transmit carrier is turned on and off by the pulse width (A1 emission) set by the pulse train. In the aircraft, demodulated pulses come from the receiver, which is of standard superhet design, to the decoder board. Here, the clock pulse enables the circuitry to route the first pulse after the clock to the elevator, the next pulse to the ailerons, and so on, until all seven data pulses are distributed to the proper servos.

A servo is an electronically-controlled electric motor. It moves an arm that is mechanically connected to whatever control on the plane you wish to control. When the data pulse enters the servo, it is compared to an on-board pulse-generator output which is controlled by a pot, physically positioned by the servo output arm. The on-board pulse is determined by where the arm is currently, while the data pulse from the ground indicates where the pilot wants the arm to be positioned. A difference between these two pulses produces an error, which causes the servo motor to rotate in the proper direction to move the arm/pot combination to reduce the error. At zero error, the motor stops and the servo idles, waiting for a new position indication to be sent up from the ground via the pulse train. While the transmission method is digital pulse, the net effect on the plane is smooth control, since the pulse-recurrence frequency is high enough to preclude stepping of the controls.

In actual use, all this highbrow theory is not important to the pilot and his plane. As the pilot thinks "let's do an axial right roll," his thumb moves the transmitter's right stick to the right, and as the plane half-rolls to inverted, he pushes the stick forward for down elevator, holding the nose up as the second half of the

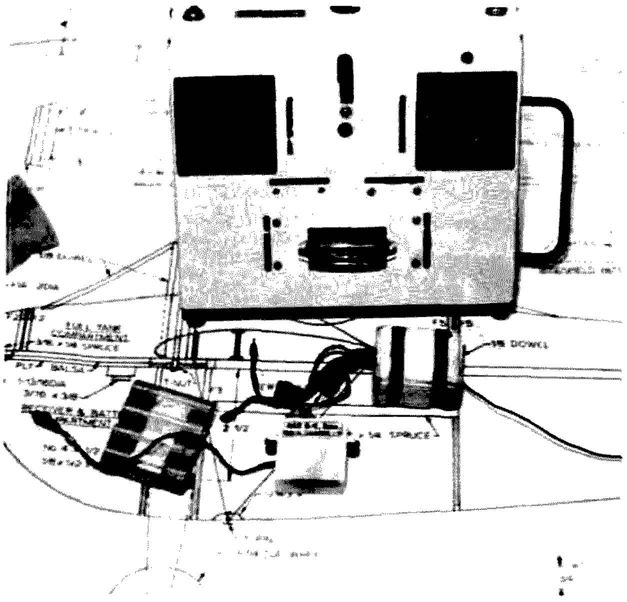

Photo B. The system buttoned up and ready to install in the aircraft. A 6PDT switch (not shown) turns the airborne unit on and off. The receiver/decoder case is covered with thin foam rubber for protection. The servo at lower center is one of four in the basic system.

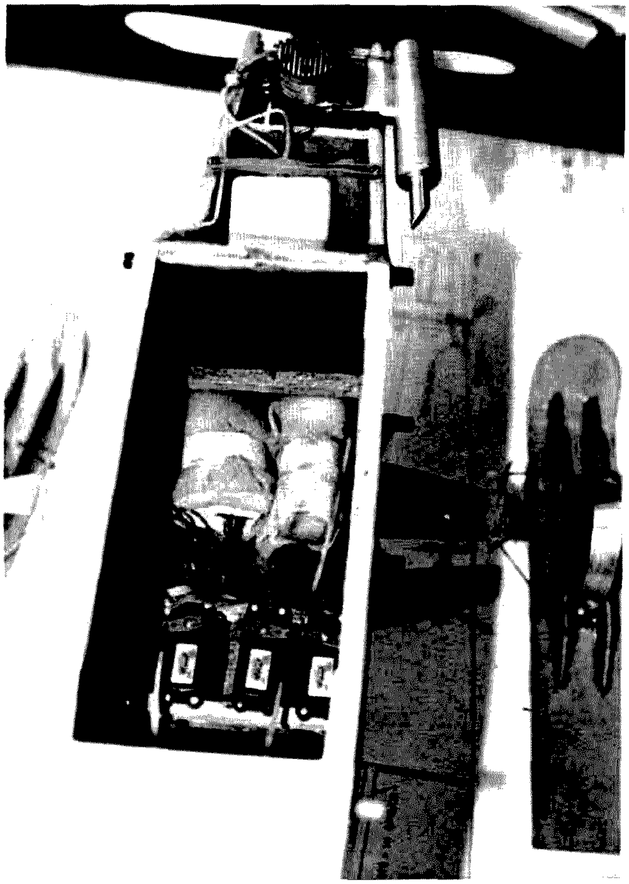

Photo C. The radio room of a typical powered aircraft. Receiver/decoder and battery are both wrapped in one-inch foam to dampen vibration from the engine. The three servos control rudder, elevator, and motor speed.

roll is completed. The system allows the pilot to make the plane behave realistically, as if under the guidance of a miniature pilot. It allows the pilot to fly famous historical aircraft in the same way that the full-size aircraft were operated, and to try new designs with no personal risk.

The instructions for building the kit are laid out in the same fashion that Heathkit uses. Each step is checked off, with nothing left to chance. The many illustrations make parts placement easy. While the whole system is complex, the sequence of assembly and attention to the smallest detail make it one of the easiest kits to build.

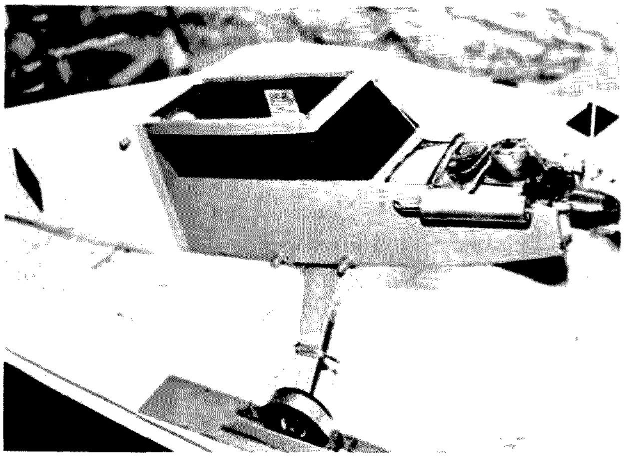

Photo D. The aircraft minus its wing. Power is a .40-cubic-inch engine with 10-inch diameter propeller. The fuel tank (just behind the engine) carries 13 ounces of model engine fuel. The skis are required for operation in that "flakey sunshine" so common to winter in the northeast.

Unlike most amateur gear, this radio operates in a very hostile environment. In powered planes, the engine is a single-cylinder unit and not very well balanced. This 20,000-rpm massage will loosen a poor solder joint in short order. Any metal-to-metal contact produces static noise which can jam the incoming data stream to the receiver. If severe enough, the noise will effectively lengthen the pulses, making the servos all run to one extreme, which could result in a spiral dive into the ground.

Nicad batteries in the transmitter and airborne system have their own requirements of care and feeding and dislike vibration as much as the circuitry does. By using heat-shrink tubing over connector/wire junctions, taping batteries together solidly, and wrapping the receiver and battery pack in foam rubber, the effects of vibration will be greatly lessened.

Ongoing maintenance is the only way to keep the radio from having trouble. To help with this, a monitoring system was built into the transmitter to check on vital voltages. At the top right corner of the transmitter case, a small LED is mounted in a grommet. The LED will not light on less than 8.9 volts and is wired across the string of eight AA cells, which are 9.6 volts at full charge. When the LED goes out, very little time remains for the pilot to land the plane, or gravity will do it for him.

The transmitter encoder uses about 6.0 volts from the battery. A bad cell would not put out the LED, but may tear up the pulse train at the encoder board. For this reason, the meter at the lower center of the transmitter case monitors encoder current and is much easier to see than the LED in full daylight.

Tests of the airborne battery are made using a Heathkit expanded-scale voltmeter, Model GD-1188. It costs about $17.00 and reads the battery under simulated load. Using a mating plug, the meter is connected to the battery through the charging jack at the on-off switch. This tests the cells, all the wiring, and the switch itself, so items most likely to cause trouble are tested as a unit. This is the last check made before the plane is closed up for the day's flying.

The model airplane version of Murphy's Law states that your radio will become inoperative only on the day before the big contest. With a factory-built rig, the only option is to return the radio for service and miss the fun. With kits, all the prints and schematics are on hand, and by knowing how the radio went together originally, the chances of beating Murphy and fixing the problem are very good.

No matter what type of plane your rig ends up controlling—be it a highly-detailed scale fighter or a simple glider—there is no feeling quite like the one you get from flying a plane and radio that you built yourself. And come contest day, when it's time to hand in your transmitter at the impound desk, it will feel great to be able to say to the official that your rig is the custom job on six meters. ■

All the News that Fits

—make your club newspaper a winner!

Wouldn't it be neat if . . .! It would be a great idea to have our own . . .! What great editorials I could write . . .!

Have you had these ideas in your mind lately, only to be stymied by the logistics involved? Do you have newsprint in your veins? Were you captivated, as a child, by the miniature print set you received from Santa Claus? (I never did get the knack of setting the type correctly with my super duper mini-print shop.) Have you mentioned the idea of having your own newspaper at a club meeting only to open the floodgates to who, what, where, why, and, more to the point, how?

Let's investigate the possibilities.

Why have a club newspaper? Amateur radio is communication. Most news is spread via the radio on club nets. So why have a newspaper? The same argument could be applied to television news. Most of us watch the up-to-the-minute local and international news on our favorite TV channel, but many of us also grope in the early dawn to fish out the newspaper from the bushes to read what we heard about the night before. Newpapers give substance to the news. We can learn more when we read (and reread). When the facts are clearly stated in black and white, then we learn at leisure.

We read newspapers to find out what's happening, to catch up on what we missed, and to learn more details about the events we're interested in—to be in the know.

Club newspapers do all this and more. More, because it's a local paper giving tidbits of information about people we know and things we ourselves are involved with. The club newspaper is a uniting factor, keeping everyone up to date and making members more active. Even inactive members feel more a part of the club when they read their club newspaper.

Although club activities are important to club members, most things are not national news to be printed in *QST* or other amateur journals. So, members have a chance to see their name in print, to be congratulated in upgrading or to be congratulated (or consoled) on their recent marriage, or birth of a new baby or grandchild, or anniversary—things that are important to us as people. (Much to the amazement of many, hams are people, too!) The club newspaper unites members on a social basis.

A ham is more likely to communicate about his latest antenna than to mention on the air that he is a newlywed or that the new baby is keeping him up nights. Getting to know one another on a social basis as well as on the air is a good way of keeping a club active and growing. We feel more like friends than just radio comrades.

Club newspapers are more than just club newspapers. That's right, club newspapers are publicity or public relations for amateur radio. The best public relations are not necessarily the biggest, flashiest commercials with catchy tunes behind them. The best public relations is everyday personal contact.

Ask a doctor or dentist what his best source of advertising is. He will probably tell you he doesn't advertise, that his patients are referred from other patients (word of mouth). Even with regard to a movie or a show or a restaurant, we tend to value our friends' opinions and recommendations. Their personal comments will sway us. If Tom said the restaurant had terrific food, Dick might try it. If he doesn't like the food, he'll think Tom has terrible taste.

But he tries it; he looks into it because his friend suggested it. With hundreds of thousands of amateurs around, amateur radio has its best publicity potential in its own people. This tells us all to be amateur radio conscious. Mention it in conversations; wear "I Am a Ham" T-shirts. T-shirt slogans are the rage. Everyone wears them. How about "Ride the Radio Waves with Amateur Radio"? Think of something creative and wear it! Wear your handheld radio on your belt. (Don't forget the ham radio belt buckle.) When people ask you if you're a police-

man, say, "No. This is amateur radio." Pull out a copy of your club newsletter and hand it to them.

You see, your club newsletter makes amateur radio a more tangible thing. People can look at it, read it, and perhaps become curious about "these crazy people." (I have wondered in the past if it is a requirement that a person be crazy to become a ham.) One way or another, the whole world is crazy, so we're all susceptible to the magic of amateur radio. All amateur radio needs is exposure.

Take extra copies of your newsletter with you in your car and pass them around. Leave them in your employee cafeteria for others to see. Give beginning amateur radio books and kits for Christmas presents. Start a ham station where you work. In amateur radio publicity, it's the little things that count. If everyone does a little, amateur radio will have a lot.

In our investigation of "why" an amateur radio club newsletter, we have delved into the "what." A club newspaper can be anything from a one-page edition to a twelve-page paper (or more).

Where does the money come from? Most clubs are their own publishers and take the funds from the club treasury. Usually, the treasury is supplied from club dues, hamfests that were held, or even raffle money. It is evident that in most clubs the treasury is not an unlimited source of supply.

Cost is a relevant factor in the type of newspaper your club will have—the kind of paper, printing, number of pages, etc. One big expense is postage. Check to see if your club qualifies for nonprofit bulk mailing privileges with the post office. However, going first class does have its advantages. The main advantage is that the member receives the newspaper within a respectable amount of time. I have received bulk mail as much as two weeks after the proposed event even though the senders felt they mailed it early.

Most club newspapers that I have seen use one 15-cent stamp and sometimes have double issues with 28 cents in stamps. If standard 8½" × 11" paper with a sub weight of 20 is used, one stamp will cover six sheets (12 pages) if no envelope is used. Just fold over the newsletter and address the bottom half of the last page and staple. Or five sheets (10 pages) can be sent in a standard size envelope with one stamp. (Warning: The post office is always changing its rates and rules, so keep abreast of the latest with your local post office.)

A club newsletter, first of all, contains club news: the date, time, and place of the next meeting and a description of the program for the meeting. Lists of activities such as foxhunting, Field Day, radio calibrating day, club picnic, a Christmas party, or anything that the club is currently involved in, can be put into the club paper.

Next, include congratulations to the members on upgrading and any personal notes that you can dig up during the month. Then, depending on the amount of space left, you can fill in with amateur-related articles such as: comments on amateur radio news at large, regulations, FCC changes, antennas, etc. Anything and everything that the editor and members can think of can be put in the club newsletter, except politics. The club newspaper is a written account of club activities and members' interests.

Who? is always the 64-thousand-dollar question. Be assured, if you bring up the idea, you will be the first one considered for the job of editor. Experience is useful in any case, but not a real consideration. The real consideration is the willingness to do the job. Some clubs just make it the responsibility of one of the officers, such as a vice-president, for a one-year term. Somehow it's not so bad to know that you only have to do 11 issues. (You get one issue off for summer vacation.)

No matter who is the editor or responsible person for the newsletter, he/she will need the cooperation of the whole club. There is nothing more frustrating for an editor than to be at deadline and not have the necessary information. An editor is not an investigative reporter who has to sift through all the scuttlebutt and info to find the true facts. An editor reports the news as given to him.

Where does all this news come from? *The members!* If someone is a little too modest to report an upgrade such as passing the Extra exam when all he was trying for was his Novice license, then one of his friends should report it. It is up to the members to keep the newsletter interesting. Too many members think, "Oh, they'll hear about it." Or, "That's not important enough." *Anything* concerning the members is of interest in a club newspaper.

It is the responsibility of the editor to correlate all of the various items and to lay out the material on the pages. The editor cannot manufacture news. Since this is a volunteer, non-paying, do-it-in-your-free-time-when-you-could-be-DXing job, the editor does not have the time to search out stories. The more people who contribute to the newsletter, the more of a club newspaper it is, instead of just a one-man show.

One thing I have found: Don't just ask in general for people to contribute information or articles. An editor must impose upon his friends. "I heard about your new antenna, Bill. Would you please write something up on it? Anything at all, Bill, that you want to tell us about your new antenna." You must ask directly on a specific topic. The more people you ask, the better your chances are of getting any copy back in return. Many members are surprised that you are even interested in their projects and are happy to comply with your request. (Maybe not happy, but they grit their teeth and do it.)

An editor's job is to plan. After relevant club news, any other articles or info of interest to amateur radio in general can be included, depending upon the amount of space available. This is why it's so important to have a specific deadline. When the deadline comes, the editor gathers all the information submitted to him during the past month and figures out how much space different articles need and what looks good where.

Don't despair. It's not really hard and the more you do it, the easier it becomes. But let me repeat—there is nothing more frustrating for an editor than to be at deadline and not to have the information needed. A joy of an editor's life is having too much material! Then he can plan what will go into the next issue and be that much ahead of the game.

It's just too easy to let the other guy do it. If a newspaper is to be successful, the members must cooperate. The beauty of it is that the members really don't have to do very much. Each gives a little and the news comes flowing in. Letters to the editor are always interesting. Members can send in their public service reports such as calling in traffic accidents and other related public service info. The local ARES EC can submit material to the editor about

ARES activites or even just give pep talks via the newsletter. But the vehicle of the newsletter must be used or it will die or atrophy. If the members don't care enough to send in the material, after a while the editor will feel that he is wasting his time.

The form in which the material for the newsletter is sent depends upon the individual club. The varying factors are many. Some editors (or a club typist) type up the entire newsletter and send it to the printer. Others give out specifications on, for example, margins and ask that the individuals hand in the material already typed. The editor then pastes up the various articles, using rubber cement. Many editors are just happy to receive the material and ask only that the handwriting be legible!

Keep in mind credit lines. It's wrong just to copy someone else's work word for word and pass it on as your own. If it's copyrighted, then write to the party involved to get permission to reprint. This is very simple to do and most people are glad to give a nonprofit organization cooperation. If your source is another newsletter, just be sure to give a credit line to the author of the article and the newsletter in which you found it. The Golden Rule is certainly applicable in this situation.

One great source of extra information (filler) is the National Aeronautics and Space Administration's publication, *Tech Briefs*. This is a collection of the various research and development projects carried on by NASA. *Tech Briefs* applies space technology to Earth problems. It's an impressive publication, sent out quarterly. There is usually something of interest to hams in the publication. When I wrote for permission to reprint, the reply, from Louis Mogavero, Director, Technology Utilization Office, was:

"NASA *Tech Briefs*, once published, are considered to be in the public domain. They may be reprinted by anyone, without permission from NASA."

If you're interested in receiving a copy, just write to: Director, Technology Utilization Office, PO Box 8757, Baltimore/Washington International Airport MD 21240.

Another good source that gives permission for reprinting is *HR Report*. *HR Report* is an up-to-the-minute newsletter published weekly, reporting happenings in amateur radio across the country. It makes great filler copy. All they ask is that a proper credit line be given. If you're interested in receiving it, write: *HR Report*, Greenville NH 03048.

Worldradio News is an amateur newspaper published monthly concerning radio news in the world. They say, "*Worldradio* is an international conversation. You are invited to take part. Our newspaper is written by its readers.

"Our goal is to be a valuable resource of ideas and experiences beneficial to the amateur radio community. We publicize and support the efforts of those who bring the flame of vitality into this avocation."

Editors of club newspapers may exchange their newsletter for a copy of *Worldradio News*. They also automatically grant permission to reprint. If you're interested, write: Worldradio, Inc., 2120 28th Street, Sacramento CA 95818.

Another interesting untapped source of information is your own collection of amateur radio contacts. Along with my QSL cards to foreign lands, I enclose a note with a copy of the newsletter, asking for stories about amateur radio in their countries or just information on themselves. Everything considered, I've gotten terrific response. I always send them a copy of the newsletter with their story, written in their own words, with their byline. This is a good way for amateurs to create international goodwill. Not only that, it's educational for us to learn about how others in the world operate and live. Communication between people is the only hope for world peace.

How to get your paper printed is a goodie as far as problems go. The best thing is to find a ham who is also a printer, and use your power of persuasion to have him print up the newsletter. If you have the president of a large company like Xerox® in your club, persuade him to volunteer, and you're in like Flynn!

Lee Knirko W9MOL is editor of *QCC News*, the publication of the Chicago Area Chapter of the Quarter Century Wireless Association; also, he was president of the Amateur Radio News Service. Lee suggests:

"There are generally three ways to produce a paper. Offset press, photo process (Xerox or other electrostatic copier), and duplicator. Each has its advantages and disadvantages, including the cost per page. Generally, though, clubs usually use what is available. Particularly when it is free or cheap! Finding a ham printer using offset is the best of all worlds because of the flexibility and low cost per page, particularly if a fairly large quantity is printed, say over 200-300 copies. If fewer than, say, 25 copies are distributed, offset is expensive and one of the other methods is more favorable."

Xerox is a popular process used with club newspapers. Lee says:

"Many, but not all, tricks available to offset reproduction can be done with Xerox. You can reduce (8-1/2" × 11 from 11" × 14" is the most favorable), print two sides, and automatically collate. The quality is not as good as offset, particularly for photos (screening helps), large black areas, or material previously Xeroxed. We now pay about $75 an issue for 250 copies including photos and other graphics at my local ham printer."

Club finances, of course, influence the number of pages and type of printing done for the newsletter. There is only one way to find out the best method for you and your club: trial and error (which also is known as "Research and Development"). As Lee W9MOL says, "Bear in mind that reproduction quality is *not* the most important element in a club paper. If the *content* is there for *your readers*, they won't care how it's reproduced."

One nice thing about editing a club paper is that you get very few complaints. (I wonder why . . . ?)

Eeks!! What do I say? You simply report the news in your own words. Everyone has his own style of writing. Keep in mind to have the five Ws—who, what, where, why, and when; you won't go too far wrong. Lee W9MOL has more advice:

"Before starting on an issue, you need to make a list of everything you might put into your paper. Then you need to type the material or get someone else to type it for you. You then pick and choose, expand or contract, to fit space needs. The first sentence is the 'grabber' designed to catch the readers' attention so they'll read on. Get some sample newsletters and study them for help in developing your own style."

Also have a standby dictionary. It's amazing how simple words don't "look" right when you know it's going to be printed hundreds of times. See if you can coerce someone to proofread for you. When you're familiar with the content and

writing, it's very hard to find your own mistakes until after it's printed. Then every error sticks out like a sore thumb.

Another help for editors is the Amateur Radio News Service: a volunteer organization dedicated to helping anyone involved with PR work or newspapers. Once a month, ideas are pooled from editors and PR people from all over the country and are printed in the *Bulletin*. They also have a booklet that is sent to new members entitled *The Club Paper*, which goes into detail as to the mechanical aspects of printing. If you're interested, write to Fran Norrick WB9WPS, Secretary, ARNS, Route 6, Box 239, Kankakee IL 60901.

Be an administrative editor. This is your chance to be an executive! As Lee says, "Consider the administrative editor who persuades his or her club's officers and members to submit good material, finds someone who likes to draw cartoons, recruits some volunteer typists, locates a ham printer, organizes a circulation committee, and oversees to see that they have the finest paper for the club."

The more reporters you can assign, the more columnists you can draft, the more fun your newsletter can be for the club members.

If you know of any ham who is into computers, draft him to do the address labels. Appoint a committee to be responsible for collating (putting the pages in order), stapling, addressing, and mailing. Don't forget the stamps!

Make your next club project your club newsletter. Participation is the key to success. Cooperation is the byword.

Do it! Be it! Say it! Amateur radio news—write it today.■

My Infernal Tower

—tales of a flying fiasco

Up! The higher the better! My Novice antenna was barely high enough to walk under. The next one wasn't much above the roof. Higher! Tie sawmill scraps together with coathangers. Guy them to the fence and the woodshed with baling wire. Get that droopy dipole up there!

Good enough? No. Crooked as a dog's leg, and ugly besides. And with all the effort, it isn't as high as the electric wires to the east. And there is still 200 feet of rock to the west. Signals coming in all the way from Hawaii are not tough enough to penetrate much rock. Maybe there isn't such a thing as "good enough." Maybe "good enough" is just an illusion.

A man came to my store and traded a nice TV antenna and mast for some used duffel bags. Before the sun went down, that hardware was all standing on end. TV reception was better, even if the programs weren't. The FM station from fifty miles over the mountains came in perfectly. We could listen to beautiful music. And I had a taller skyhook. That was the real motive.

W7KJM lent me an inverted vee and an NCX-3. I tied a dead padlock to a length of nylon line and slung it over the TV antenna and hauled up that loaner. Aha! Forty meters is mine!

But even the top of the thing is lower than the highlines. *Nothing* would do but a tower. But towers seem to start at a month's wages. And they have no upper limit. Besides, it seemed sinful to spend anything on a *hobby* as long as I still owed on the homestead mortgage. ("Mort" is Latin for "dead." "Gage" is Latin for "pay-'til-you-are.")

The Final Solution

Anyway, one fine day we made a last back-breaking payment and the mortgage company sent us our title. And a few days after that an ad appeared:

> COLOR TV $75. Waterbed $100. 30' aluminum twoer [sic] $90. Trash-trailer $250. 537-XXXX

Now, a "twoer" thirty feet long might be a boat—but not for $90. Then, again, it might be a tower. It was a long-distance call, but I dialed during daylight.

"Popopopopop. Popopop. Popopopopopo pop," etc. "B-r-r-r-r-r-r-r. B-r-r-r-r-r-r-r," etc.

"Raunchy Realty. Betty speaking. May I help you?"

"You advertised a tower for ninety dollars?"

"Yes, sir. Would you like to look at it?"

"Yes, ma'am. Could you tell me . . .?"

"Yes, sir. We'll have it all cleaned out and the lights on by tomorrow noon."

"Lights?"

"Naturally."

"On a thirty-foot tower?"

"Tower?"

"Yes, ma'am. Tower. Maybe I have a wrong number. Excuse me."

I hung up and dialed again.

"Raunchy Realty. Betty speaking."

"Uh, this is me again. Is somebody in the office selling a tower?"

"Wait. I don't know. Uh, I thought you wanted to rent that garage for ninety dollars. Fred. Ff-rr-ee-dd! Somebody wants a tower."

"Tower? Oh, yeah," I heard in the background, along with a typewriter. "George has one he wants to get rid of. It's that pile of scrap iron in the alley."

It was fifty miles away. We were there very shortly. George was not there but his tower was. It looked so pitiful lying in three pieces by the garbage cans. It didn't look like it would even reach the eaves, much less the high-lines. I picked up a section in each hand. It was not aluminum, but steel. Even so, it didn't weigh much. I had really expected something much, much heavier. On the other hand, the sections seemed stiff enough, braced that way.

Well, this was what I came for. George showed up and I paid him with money I had borrowed on my credit card. We went home, and the thing laid out behind the house for an unconscionably long time.

The most obvious thing to do was to dig a big hole next to the peak of the roof, stand the bottom section in it, and fill the excavation with wet cement. I could bolt on the other sections after the concrete cured and brace it to the house.

No. That was the only direction we could ever hope to build onto our house.

By-n-by, I traded a fairly good swivel chair (that only needed a little welding and only had a small rip in the cushion) for three unequal lengths of nearly straight one-inch pipe with only a little surface rust. They would not fit into the tower legs. After two hours of hard filing, they were still a smidgen too big. I took them to the welder. He told me what it would cost to turn them down on his lathe. Too much. Inspiration struck. I took the pipes to the hardware store. For a buck, the nice man threaded the first four inches on each one. That reduced the diameter a little and they fit into the tower legs just fine.

I dug a hole and calculated the amount of concrete to fill it up. Fifty bucks?! No way!

I bought ten bucks worth of instant-mix concrete and gathered about a ton of rocks. I joined the pipes to the bottom of a tower section and stood it up in the bottom of the hole and plumbed it with a carpenter's level. The carpenter was using some other tool at the time and didn't mind a bit.

By choosing the rocks carefully, there was not a lot of space between them. A layer of rocks and a pour of soupy cement poked down with a stick; another layer of chunks and more liquid stone. The pre-mix and the stones and the hole came out remarkably even. I smoothed it off immediately and again an hour later. At sundown, I carved a date in it and covered it with dirt so it wouldn't dry out before it had a chance to cure. (Contrary to common belief, concrete does not harden by drying out. It actually combines with the water and becomes a different sort of substance.)

There stood my stub of a tower for a long time. It began to look like the situation described in Luke 14:28-30. I climbed up, balancing the second section on end, and tried to fit it on top of the first. Maybe it can be done. Maybe a suicidal maniac will accomplish such a thing, someday. I won't try it again. Ever.

Success By Committee

W7KJM promised me a crew for an antenna-raising party if I would put the whole thing together. So, I got all the bolts, insulators, guy wire, and turnbuckles I thought I needed. I set the guy anchor posts deep in the ground and tamped buckets of rocks around them. I took that lonesome section off its makeshift base and put the whole tower together and attached the guys.

Exactly at the appointed hour, Ed, Ray, Paddy, Bob, Randy, and Dick drove up in a convoy.

One minute later they were all driving away again. The tower was up and guyed. They barely stopped for the sandwiches and Kool-Aid my wife brought out to the "party." They wouldn't accept pay or thanks.

"That's what ham buddies are for, Glenn."

That was quite a while back. I admire the tower every day. (What else is it good for? I don't have an antenna to put on it.) I climb it sometimes for the superb view from the top. I made a brace for the base because those three pipes go eye-high out of the ground before the tower even begins.

Today I bought nine feet of 1¼-inch pipe for a mast. It was a foot too long to go into the tower from the side. No way was I going to carry it up to the top and try to stuff it into the socket from above. At the price I paid, I sure didn't want to saw off a foot of it. Finally, I dug a hole in the ground and shoved the mast into the tower *from below ground*.

It is night. As I write this, my tower and mast rise way above the electric wires. Maybe I will have an antenna soon. There's this guy down in Phoenix with a 20m beam for sale. If he'll just wait until the garage-man finishes putting a new motor in my pickup, I'll borrow some money on my credit card again and go buy it. It's only a five-hundred-mile round trip, and I want to take my children to visit their grandparents, anyway. ■

Apples: Five Bits or Eight

—tired of "Space Invaders"? Then turn your Apple II on to RTTY!

Carl Jensen WB6MEP
9842 Palais Road
Anaheim CA 92804

If you have run out of things to do with your Apple II lately, you might like to try this project. It will get you operating on 5-bit RTTY and, with a little rewiring, 8-bit ASCII also. For 8-bit ASCII, you will have to rewrite the program. The Apple II interface in Fig. 1 is built around the COM 2502 UART. The AY5-1013 is an exact replacement and may be used. The system can be used with any SSB or FM transceiver.

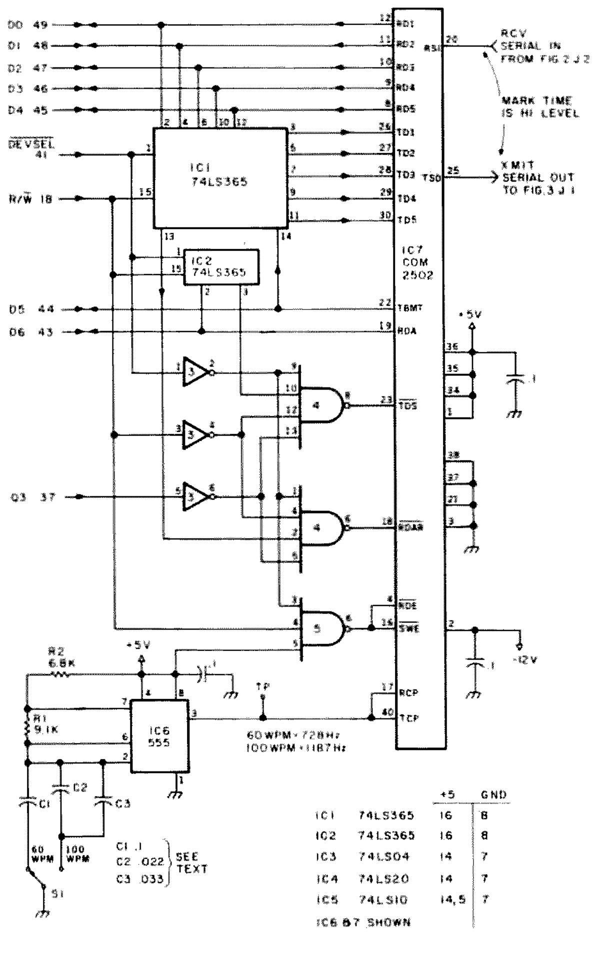

Fig. 1. Apple II interface.

How It Works

See Fig. 1. During receive, the UART accepts serial data at pin 20, RSI. When one complete character has been received, it is available in parallel form at RD1 through RD5. We know this character is ready when RDA goes high. RDA is tied to the Apple's data-bus bit 6 which we test in the program. The character is processed and printed on your TV monitor. Next, the Apple sends $\overline{\text{RDAR}}$ on bit 5, which resets RDA to low so that we can tell when the next character comes in.

During transmit, the UART tells us it is ready to transmit the next character by bringing TBMT high. TBMT is tied to data-bus bit 5. When the Apple detects bit 5 high, it puts the next character to be transmitted on data-bus bits 0 through 4 and sets bit 6 high also. Bit 6 high is $\overline{\text{TDS}}$ and enters the character into the UART at TD1 through TD5. The UART then clocks the character out serially at TSO. One start bit and two stop bits are added by the UART.

Enabling $\overline{\text{RDE}}$ and $\overline{\text{SWE}}$ puts the received data and status bits on the data bus. When not enabled, these outputs are at a high impedance and will not disturb Apple operation. IC6 is the 16× clock generator. Provision is made for either 60- or 100-wpm operation.

Fig. 2 is the demodulator. Receiver audio is fed into J1 from your receiver headphone jack. The speaker is handy for listening to incoming signals. The audio bandpass filter is not necessary but can help with QRM and QRN. Also, the output of the filter can be fed to a scope for use as a tuning indicator of sorts. More on this later. I used an Autek filter. You can use any kind of filter you wish, or none at all. During FSK, when the demodulator senses a 2295-Hz tone, it puts out a high level at J2. When a 2125-Hz

tone comes in, it puts out a low level. In FSK (10 meters and below), 2295 Hz is used as the mark time; 2125 Hz is used as the space. This gives a downward shift of 170 Hz. In AFSK (6 meters and above), the tones are reversed. S1 selects FSK or AFSK and will be labeled during alignment.

Fig. 3 is the modulator. The input at J1 is from the serial output of the UART. For a high input, we get a 2295-Hz tone at J2. A low input gives us 2125 Hz out. The output of the XR210 is made into a sine wave by the low-pass filter so that our transmit signal will not be too wide. The filter cutoff is about 3 kHz. S1 allows you to identify in CW. S2 is wired in at the mike jack the same way as a PTT switch. S3 selects FSK or AFSK.

Construction

The interface is built on an Apple hobby/prototype board, Apple part number A2B0001X. This board is made to plug into the I/O slots at the back of the Apple. S1 is brought out in back of the Apple so that you can get at it. No layout is included with this project because nothing is critical. You should have no trouble if good general construction practice is used. Capacitors C1, C2, and C3 must be of good quality, like mylar™ or polystyrene. It is a good idea to construct the IC6 circuit on an experimental basis first and trim C1, C2, and C3 to get the clock frequency within 1%. A frequency counter is the only good way to do this. At 60 wpm, the frequency at IC6, pin 3, should be 728 Hz plus or minus 7 Hz. At 100 wpm, it will be 1187 Hz plus or minus 10 Hz. This trimming can be done with small value mica or ceramic capacitors. After you have built the circuit on the Apple board, check the clocks again. They may need a little more trimming.

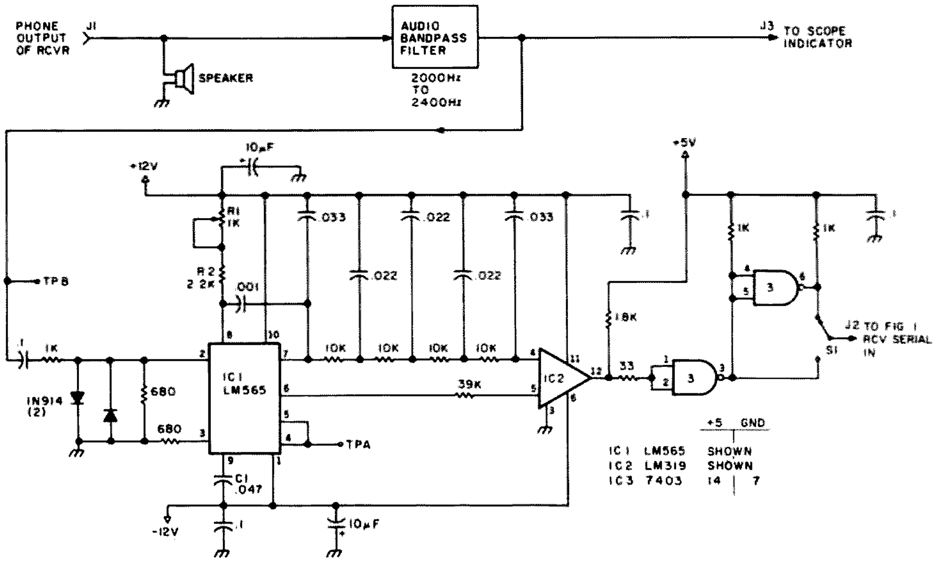

Fig. 2. Demodulator schematic diagram.

My SSB phone-jack output is 8 Ohms, so a speaker at J1 works fine (see Fig. 2). If yours has a higher impedance, you may need a transformer to match to the speaker. The power supply for Figs. 2 and 3 is separate from the Apple. If you wish, you could use power from the Apple for these circuits also. C1 should be a good quality capacitor. S1 is brought out to the front panel.

C1 in the modulator (Fig. 3) should be of good quality. S1, S2, and S3 are brought out to the front panel. The chokes are the common 88-mH variety or equivalent. In all circuits, resistors are quarter- or half-Watt 5%. All capacitors not mentioned may be of any type.

Alignment

First do the modulator. With S1 in normal, hook the scope to J2 and make sure you have an audio sine wave. Adjust R3 for about 1 volt or enough to run your frequency counter. Now hook the frequency counter to J2. Put S3 to FSK and short J1 to ground. Adjust R2 for 2125 Hz. If you can't get 2125 Hz, adjust both R1 and R2 for 2125 Hz. Put S3 to AFSK and adjust R1 for 2295 Hz. These controls are interacting, so go back and forth several times until you have the correct tones. The tones are very stable and will stay within 1% drift easily. Now verify the conditions listed in Table 1.

The output at J2 should be a nice-looking sine wave.

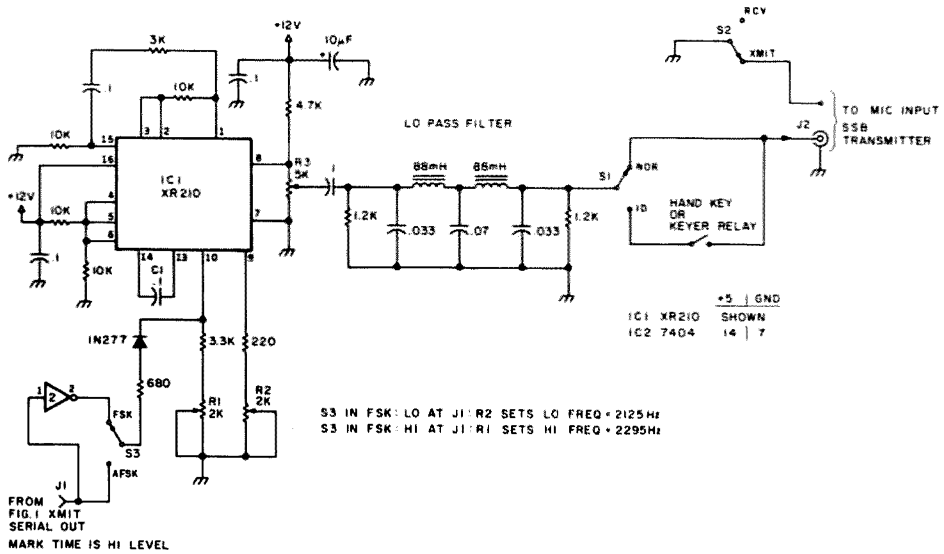

Fig. 3. Modulator. Output in FSK: mark time = 2295 Hz; space = 2125 Hz. Output in AFSK (tones are reversed): mark time = 2125 Hz; space = 2295 Hz.

Program listing.

```

If not, the low-pass filter is not working correctly. Both tones at J2 should be the same amplitude within plus or minus 10%.

Now align the demodulator. With no input at J1, hook the frequency counter to test point A at IC1, pin 4. You should be able to adjust R1 to 2200 Hz. If not, something is wrong with R1, R2, or C1. For the next alignment, we are going to use the modulator. Also, you will need a TTL symmetrical square-wave generator at about 50 Hz. The circuit of Fig. 4 gives you some tips on how to make one. Hook the output of your TTL symmetrical square-wave generator to the modulator, J1. Modulator S3 can be in either position. Modulator S1 should be in normal. Open the circuit at demodulator TP B and connect modulator J2 to the input of IC1 at TP B. Now hook the scope to demodulator J2. You should get a square wave. The crossover points will be jittery. This is normal. Now adjust demodulator R1 for a symmetrical square wave. Exactly half the square wave should be low and the other half should be high. Make sure of the following conditions: Ground modulator J1. With modulator S3 in FSK, you should have a low level at demodulator J2. If not, flip demodulator S1 to the other position. Label this position FSK. Label the opposite position AFSK. Now, with demodulator S1 in FSK, connect +5 V to modulator J1. You should get a high level at demodulator J2.

S3 to FSK	J1 grounded	output is 2125 Hz	space
S3 to FSK	J1 to +5 V	output is 2295 Hz	mark
S3 to AFSK	J1 to +5 V	output is 2125 Hz	mark
S3 to AFSK	J1 grounded	output is 2295 Hz	space

Table 1.

Now let's check out your SSB transceiver. For starters, the output of modulator J2 should be about 50 mV. Set R3 for this value. If this is not enough to drive your transmitter, then increase the level as needed. Connect modulator J2 to the mike input. Put modulator S3 to FSK, S1 to normal, +5 V to J1, transceiver mode to SSB, and mike gain off. Throw modulator S2 to XMIT; advance mike gain.

Caution! Use only enough mike gain to run your transmitter at about 40% to 50% of its rated dc plate input power on CW.

Next, you must make sure your transceiver is in USB so that the frequency shift will be downward. A good way to do this is to check transmitter frequency with your counter or listen to it on another receiver tuned to USB.

Example in FSK and USB

Your vfo equals 3620000 Hz + 2295 Hz = 3622295 Hz. This is the mark time frequency. Now connect modulator J1 to ground. Vfo equals 3620000 Hz + 2125 Hz = 3622125 Hz. This is the space frequency. Your transmitter shifted 170 Hz lower.

Operation

For the program to work as is, you must put the Apple II interface into slot number 3. Operating in transmit is easy. The return key transmits a carriage return. The left arrow key transmits a line feed. Any characters you type on the Apple keyboard that are not compatible with RTTY will print a * and nothing will be sent. You do not have to worry about letters and figures keys. The Apple automatically sends these.

On a standard RTTY printer, 72 characters may be typed before you must type line feed and carriage return. This is hard to keep track of in your head, so the Apple keeps track of how many characters you have typed after the last carriage return, and when the total is 67, the bell rings to let you know you are near the end of a line.

If you are in transmit, you type CTRL R to get to receive. If you are in receive, you type CTRL T to get to transmit. If you want to call CQ, you type CTRL C. Provision is made for special messages or character handling. CTRL A and B are provided in the program for these. Entering the program at $0900 starts you at transmit.

In receive, tune your receiver until you get good copy on the TV screen. The tones will sound high-pitched when you get good copy; with a little practice you can tune this way, but a tuning indicator is better. If you used a low-pass filter in the demodulator, you can hook a scope to J3 and tune by maximum signal on the scope. This will get you very close. The idea is to tune your receiver until the received-signal mark frequency produces a tone of 2295 Hz from your receiver. Then the space tone will be 2125 Hz, if the other fellow is using a shift of 170 Hz—which is the case about 99% of the time.

If you are going to operate on 6 or 2 meters, put all switches in AFSK. AFSK on FM is easier because there is no tuning to do if you are using a synthesized or crystal rig.

When you are trying to tune in a signal, there may be times when you just can't get good print even if the signal is strong. If this happens, try flipping demodulator S1 to the other position. The other fellow may be transmitting upside down.

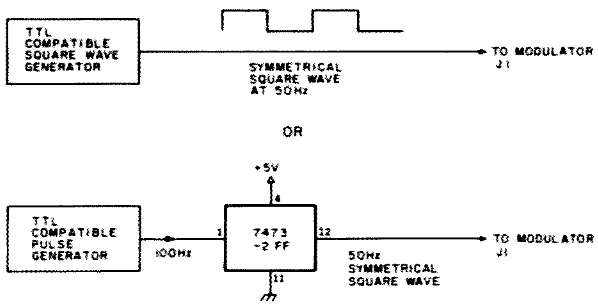

Fig. 4. Square-wave generator.

About the Program

Addresses $0800 through $083F are the characters which will be printed during receive. $0880 through $08F6 are the characters to be transmitted. You can start the program at $0900. In the CQ program data table, starting at $0A40 you use the address of the character you want to send. You get the addresses from the table located at $0880 through $08F6. For example, my call (WB6MEP) is in the program. You must change it to your call. Starting at address 0A40, the following is transmitted during CQ:

0A40	F5	letters
0A41	F5	letters
0A42	C4	D
0A43	C5	E
0A44	A0	Space
0A45	D7	W
0A46	C2	B
0A47	F6	figures
0A48	B6	6
0A49	F5	letters
0A4A	CD	M
0A4B	C5	E
0A4C	D0	P
0A4D	A0	Space
0A4E	A0	Space

Etc.

Only address low is used. The high order (08) is left out.

Any addresses not listed are "don't care," and you may use them for expansion. If you want to use CTRL A or B for special messages or character handling, you must load the starting addresses of your program at $08EF for CTRL A and 08F2 for CTRL B if you are in transmit. The same starting addresses will be at 09CC for CTRL A and 09CF for CTRL B when in receive. ■

Rotator Rescue Mission

—prevents sudden stops

It was not too long after installing the new antenna and the Ham II rotator that it happened: The tribander and two-meter beams were at top rotation speed when my finger slipped off the brake release lever. There was a loud noise that came down the tower, rippled with a chill up and down my backbone, and finally settled in my hip (wallet) pocket. Maybe omitting those torsion bars on the guy wires was a mistake. I had visions of many small broken parts scattered inside the rotator. But the Ham II is pretty well made; it all stayed together without breaking.

Since that day, special care was taken to be sure that the antenna was at a complete stop before releasing the brake lever. Then in the heat of trying to catch that six-meter station in Utah, the wrong lever was released first, again at top rotation speed. Luckily, all stayed together again.

At this point it became obvious that some ham might come along who did not know how to operate this equipment and could cause substantial damage! Protection was needed to prevent release of the brake while the antenna was rotating. If a relay was added that released the brake when either rotate lever was depressed, this same relay could be made to delay release of the brake until the antenna had stopped turning. This approach to the problem was incorporated in a Ham II rotator and is presented here for those who would like to do the same. Note that single-lever (instead of two) operation is achieved with this arrangement.

This addition to the Ham II is a very simple circuit. It uses easy-to-find parts and readily accepts substitutes from your junk box. Normal operation of the rotator is not affected; you can still use the brake and rotate levers as the factory intended. On gusty, windy days, it is convenient to use the manual brake release until the antenna has stopped being blown about. Wait for the direction indicator to show a lull, and then release the brake lever. The brake release time delay can be adjusted to suit your particular antenna installa-

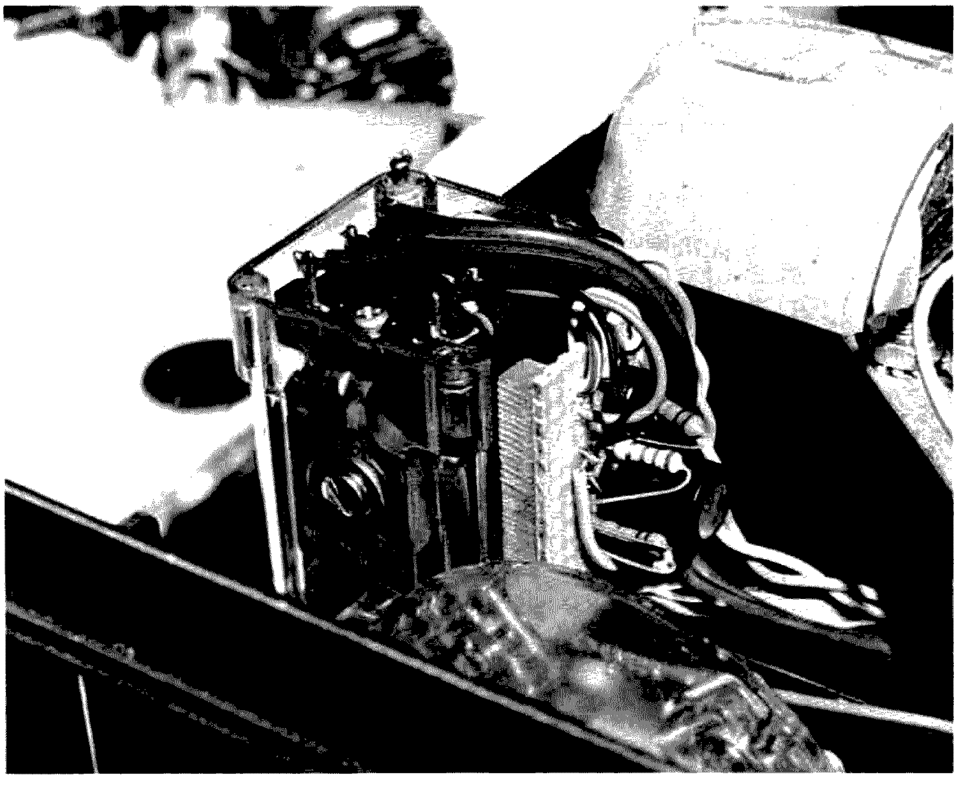

Photo A. Added relay with components on perfboard cemented to case.

tion. A two-color LED can be used to show when the brake is engaged or released, but can be omitted if you want a "no holes" installation. I understand that the Ham III rotator circuit is the same as the Ham II, so this addition should operate that rotator as well.

The Circuit

The circuit uses two microswitches above the rotate-control levers to supply power to the brake-release relay and to a capacitor for the time-delay function. The schematic is shown in Fig. 1. When either of the two microswitches is closed (by depressing a rotation-control lever), power is supplied through the resistor string to the base of the transistor, turning on the relay.

One set of the relay contacts is wired across the existing brake release microswitch. Thus, the brake is released any time a rotation control lever is depressed. Note that closing either one of the two new microswitches also charges the 47-uF capacitor through the 100-Ohm resistor. The resistor limits the charge rate and prevents the direction indicator from changing due to the otherwise sudden heavy current draw

When the microswitch is opened (the rotation control lever is released), the capacitor discharges through the resistor string and base of the transistor, keeping the relay energized until the capacitor discharges. This delay allows the antenna to come to a stop before the brake is re-engaged. The delay time is set by adjusting the 100k pot. A diode across the relay coil suppresses high voltage spikes generated by the relay's inductive kick.

Ac voltage is applied between points A and C. The two diodes across the second set of relay contacts provide positive or negative voltage (depending on the relay position) through the 1k resistor to the two-color LED. The LED is green when the brake is engaged and is red when disengaged. Power for the circuit is taken from the Ham II direction indicator (meter) circuit. Portions of that circuit are shown in Fig. 1 for reference.

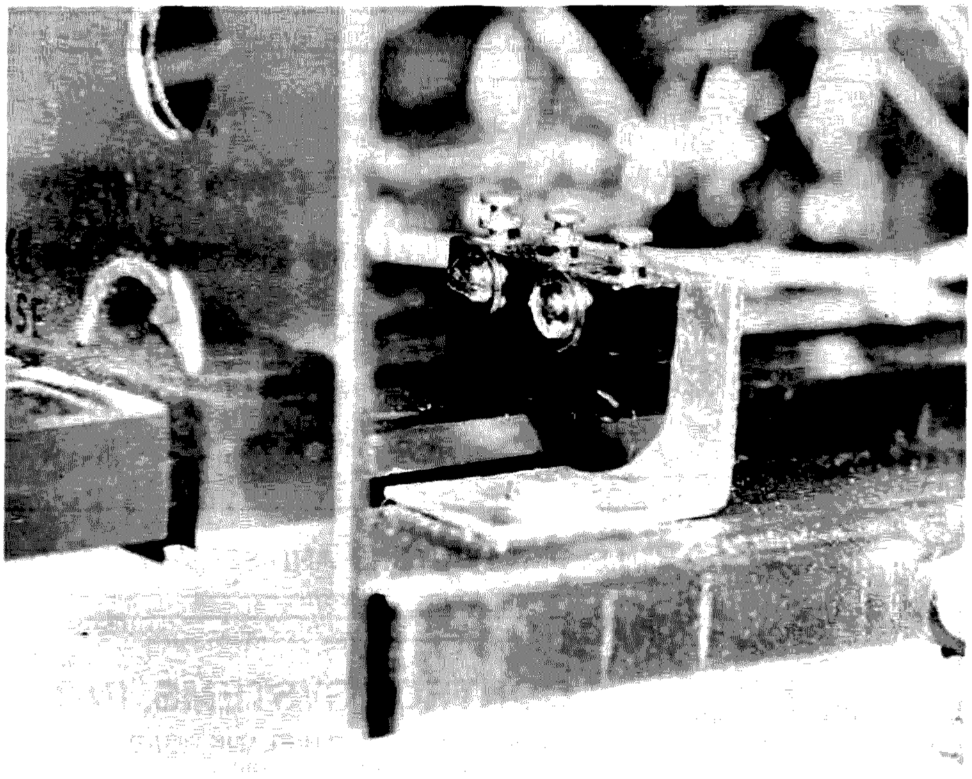

Photo B. Details of microswitch mounting.

Construction

Perfboard is the easiest way to build the circuit because of its simplicity. Point-to-point wiring using component leads is recommended. Fig 2 shows a suggested parts arrangement. The diode for inductive kick suppression is mounted directly on the relay solder lugs. The two diodes and 1k resistor for the two-color LED also are mounted on the relay lugs.

The perfboard should be wired and checked out first; then connect the relay, being sure to observe the correct polarity on the suppressor diode, and substitute a clip lead for the microswitch to test the unit. The relay should close when the clip-lead "switch" is closed and should stay closed for several seconds after the "switch" is opened. The time required for your antenna to stop should be measured and the 100k pot adjusted for that time plus about 1 or 2 seconds more.

My antenna required 2-1/2 seconds to stop after release of the rotation control, so the 100k pot was set to give a 3-1/2- second delay. The 100k pot can be measured and replaced with a fixed resistor as was done on the unit shown in the photos. The perfboard of my unit was then glued to the plastic relay enclosure on 1/8-inch stand-off strips as shown in Photo A.

A standard 1-3/8" × 1-3/8" × 2" plastic-enclosed

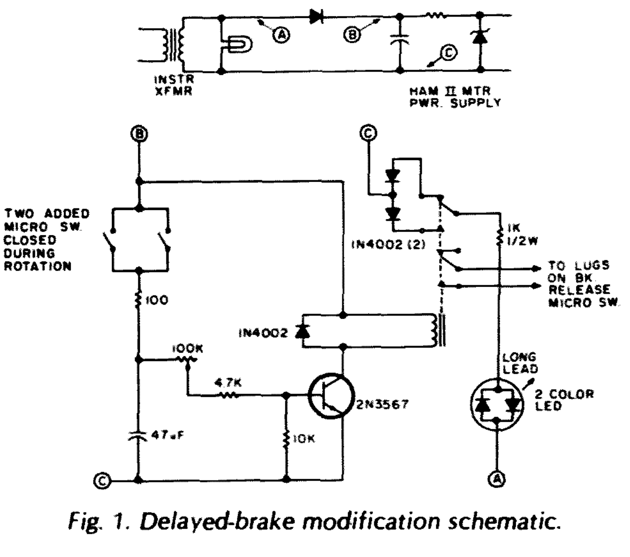

Fig. 1. Delayed-brake modification schematic.

relay will fit underneath the Ham II chassis if desired. Mine was glued to the top of the chassis just behind the meter and next to the large transformer.

The new microswitches should be mounted next. It is easiest if DPDT microswitches are used. They can be mounted above the rotation control levers, otherwise they have to be mounted below the chassis. I found small ones marked E4-111 and mounted them on small brackets as shown in Photo B. Make sure of the clearance around the on-off switch and calibration controls if you mount them on top of the chassis. Check that the new microswitches are operating properly. Add shims between the microswitch and chassis or between the switch and control lever as needed to get proper operation. Check that the original rotation-control microswitches are still operating as they should. This check is easiest to do at lugs 1 and 5 and lugs 2 and 6 of the terminal board with the rotator cable disconnected. The relay contacts should be wired in parallel with the original brake release microswitch: The easiest place to do this is at the microswitch solder lugs. The two-color LED can be installed just above the Brake Release label.

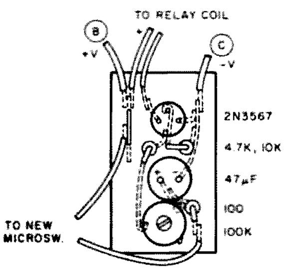

Fig. 2. Typical component arrangement.

The smoke test is next! With the rotator cable disconnected, apply power and check that the relay operates as it should when the control levers are depressed. Check that the time delay is OK and that the LED works correctly. Check that the manual brake release still works OK. Note that the LED does not respond to the manual brake release control. Now connect the rotator cable and you are in business!!

Substitutions

There is nothing critical about the circuit. Resistors of any value near those shown will produce good results. Capacitors in the range of 33 uF to 68 uF should work well. The transistor can be any good-quality NPN type, but it must have a voltage rating of 40 volts or better and reasonably good current gain (i.e., 50 to 100). The relay should be capable of operating on 12 to 20 V dc and its contacts must be able to handle the 110 V ac to the transformer.

My relay was a "hamfest special" marked 20 V dc with a 400-Ohm dc coil resistance. Its contacts looked as though they could handle 5 to 10 Amps; they were about 1/8 inch in diameter. Here is a place to use those relays that do not work very well on 12 V dc.

Diodes should be silicon and have a piv of at least 100 V. The two-color LED can be replaced with two individual ones or a single red one can be used to indicate that the brake is released.

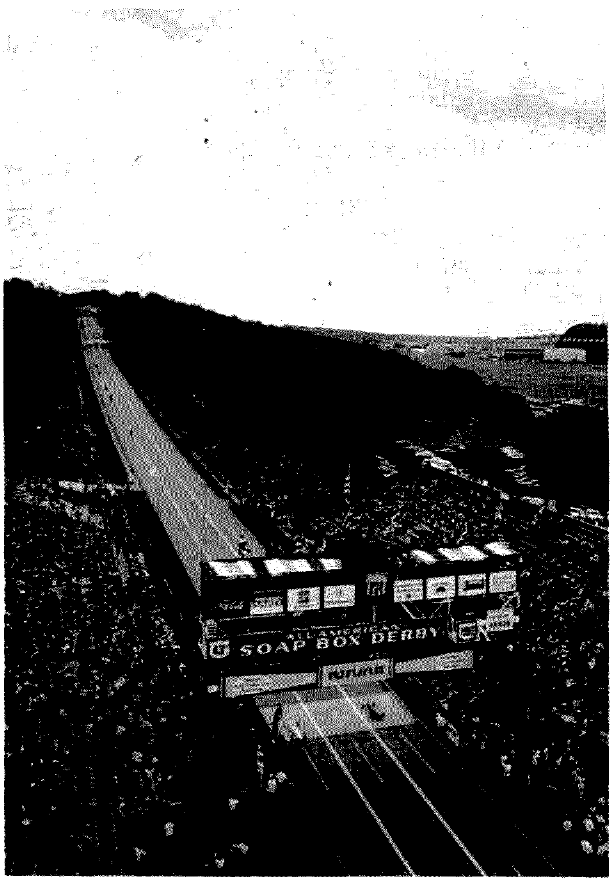
Many thanks to Paul WA2VMS/3 for discussions of ideas about this addition to the Ham II rotator and for describing a similar circuit installed in his Ham III. All of Paul's good ideas were, er,—confiscated (yes, that is the right word!) and used in this article.■

The Racer's Edge

—it was ham communications at Derby days in Akron

Henry Ruminski WD8JOI
2053 16th Street
Cuyahoga Falls OH 44223

When Dan Purol of Fair Oak, California, crossed the finish line to win the 43rd All-American Soap Box Derby, August 16, in Akron, Ohio, it was doubly appropriate that the checkered flag was waved by Jim Ott.



Derby Downs lies against a natural hill on the eastern edge of Akron Municipal Airport. It has been the scene of the All-American Soap Box Derby for 40 of the event's 43 years.

Given that honor as president of Novar Electronics, the chief sponsor of the All-American Derby, Jim Ott is KB8CT, and he was quick to praise fellow amateur operators who had provided communications for the week-long Derby activities.

"I don't know how we could have run the Derby without the hams. They provided the instant communications which made it possible to deal with any situation quickly," he said.

Wayne Alley, general manager for the All-American Derby, agreed that amateur radio made his job a lot easier.

"We spend 51 weeks preparing for this one week. Without the radio operators, it would be a lot harder. I can be anywhere I'm needed and still have immediate contact with my staff and other officials. That's especially important when I'm traveling between downtown activities and the track."

Alley's "shadow" throughout the week was Gail Wands WB8VNO, who had both 2-meter and 220-MHz handhelds for both simplex and repeater operation. Gail had one of the more active roles since Alley had to handle many questions immediately during Derby week activities and the race.

Assignments for Derby communications were handled by Tim McCleod, operations officer for the Community Amateur Radio Service (CARS) and an Akron school teacher. Communications activity was centered on the CARS .04/.64 repeater which provided excellent coverage throughout the Akron area with the handhelds most operators were using. The club station, WB8DJP, served as net control for Derby activities on the repeater, with routine traffic and rag chewing moving to other repeaters in the Akron area.

Tim's real work began on Monday when the volunteers provided communications for the welcoming of the champs at the Orangerie Plaza in downtown Akron. Since the champs were to assemble at the parking deck of the University of Akron dorms following breakfasts with their families, it was impossible to schedule their arrivals in

WB8YNX assists a parade official during the downtown parade on Friday evening. A second parade was held at Derby Downs immediately preceding the race on Saturday morning.

Workers carefully align each car at the starting line. WD8OCH and his XYL, KA8DRT, provide radio support in the booth in the background.

advance. Eighty-two senior champs had come to the city to try for the college scholarships, totaling $10,000, which went to the top three finishers. The 89 junior division champs were vying for power tools, and the top nine finishers in both classes were to receive trophies. Derby officials wanted to announce the hometown of and to give greetings to each champ on his or her arrival at the plaza. To do this, Tim arranged for operators to be on duty at the pickup point, at strategic corners downtown, and at the plaza to pass on the needed information. Each champ was correctly introduced as he arrived with a police escort.

While Gail WB8VNO was providing communications for the Derby manager, her husband, Ted Wands WD8CVH, was helping with the arrival of the champs. Another husband and wife team, the Musgraves (Scotty K8UCN, and Barb WD8DAI), were working at the pickup point with the champs.

Two other husband and wife teams assisted in the Derby communications effort. Larry Wilson WD8POL and Peggy WD8PZO assisted at "topside," the area where the cars were stored, weighed, inspected, and prepared for their run down the hill. The pair handled the post during the trial run which each contestant had on Wednesday and during the race itself. Carl Hanson WD8OCH and Audrey KA8DRT provided radio contact at the starting line on race day.

These couples were just a few of the amateurs who provided communication between the Derby Hall of Fame in the Convention Center downtown and the track throughout the week as entrants were weighed, took trial runs, and participated in the activities planned for the champs.

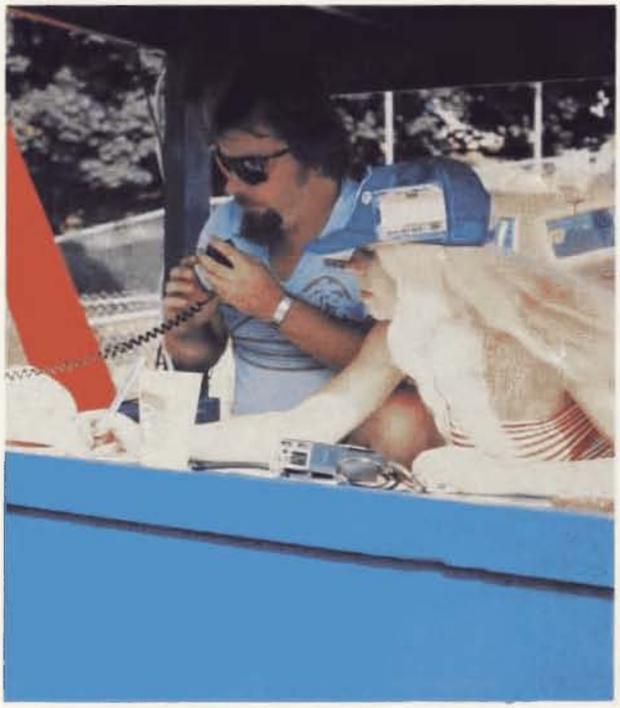
Alley and other officials were particularly impressed with the phone patch capability of the repeater.

"My secretary could find me whenever she needed me no matter where I was, simply by dialing the phone! It made my job easier and saved a lot of time. It helped things run more smoothly," Alley said.

Derby officials were quick to point out the service of Jim McCrory WD8RDW, who was home on vacation from the Ohio State School for the Blind in Columbus. Jim spent most of the week manning 2-meter and 220-MHz rigs in Derby headquarters, located under the grandstands at the track in southeast Akron. Jim, who has his General license, became a ham in 1978; he said he enjoys operating the 2-meter rig he has on loan from the Goodyear Amateur Radio Club and hopes to acquire his own rig when finances permit.

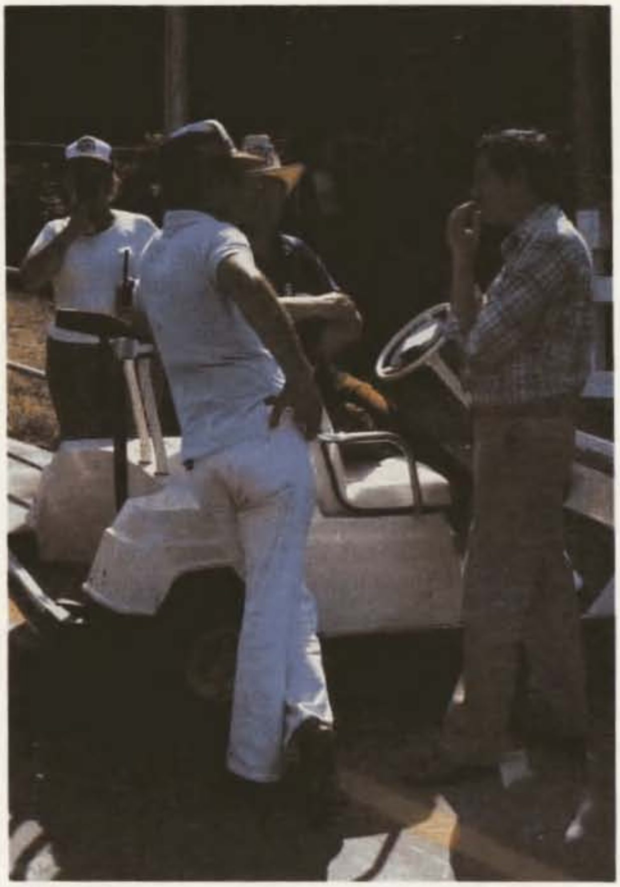
Though the activities which Jim and others helped with during the week were important, they were just more preparation for Derby officals and the communications team for the big day. Saturday, August 16, when a parade down the track, a skydiving exhibition, and 91 heats would all have to take place.

Amateur radio helped to ensure that this year's race went like clockwork. That has not always been the case. Alley recalled one incident which, while it had no serious consequences,



WD8POL and XYL, WD8PZO, work at the topside control booth during Wednesday's trial runs.

WB8VNO provided communication for Derby general manager, Wayne Alley, seen here talking to one of the deputies at the track.



WB8VNO provided communication while Derby officals discussed the race with Kazumi Hotai (right) of Tokyo Television, who taped segments for a special on children of the world.

WB8CBO (left) and WD8CVH operate CARS station WB8DJP on race day from the bridge across the race track.

was embarrassing to the people involved.

Two years ago, a skydiving team was to exit the plane, free fall, and land on the Derby track at the conclusion of the parade. A smoke grenade set off at the tower was to signal the team to jump, and the track announcer was to call the crowd's attention to the team. Unfortunately, a cannon was set off to signal the start of the parade. The smoke from the cannon apparently looked like a smoke grenade from 12,000 feet, and the skydivers arrived considerably ahead of schedule.

Since this year's Derby included another skydiving exhibition, Bruce Bechtol K8VAK flew with the team and provided both 2-meter and 220-MHz communication with Jeff Brown WD8MMN, at trackside. Jeff was to keep Bruce informed about the timing of the jump.

When Bruce arrived at the airport, the jump team and the pilot expressed some concern about the cloud cover and the wind. After a discussion, they decided to see how conditions were higher up and to make the decision then.

The wind and clouds did present a problem, and Bruce was able to inform officials on the ground of the situation. The track announcer was able to point out to the crowd that the team would be jumping from about 5000 feet with no free fall because of the conditions. In addition, radio communication also allowed the announcer to re-

WD8DAI provided radio communication for the VIP booth on race day. Immediately behind her is KB8CT, president of Novar Electronics, chief sponsor of the All-American Soap Box Derby.

WD8POL, his XYL, WD8PZO, and N8AHJ take a break at the control booth during a lull in the heats on race day.

assure the crowd quickly that one skydiver, who had been blown into a fence while landing, was not injured. The team said there would have been confusion on the ground if they had not been able to communicate the change in plans to the announcer.

With the parade and skydiving completed, the race became the important event. There were two classes, junior, for boys and girls 10 to 12, and senior, for entrants 12 to 15. A 12-year-old could choose either division, and this year's senior winner was 12.

For each heat, two or three cars, depending on the pairings, were placed on the starting blocks, the blocks were dropped, and the cars rolled down the 953-foot racing strip to the finish line where the first car across tripped an electronic timer—and a camera shutter, to provide photos for the judges in races which were too close to call with the naked eye.

After crossing the finish line, the cars had a 1,200-foot runout area in which to slow to a stop. Since each car had a brake, most stopped near the stand, about halfway through the runout area. At that point, if a winner had already been declared over the public address system, Derby volunteers consoled the "losers." (The term loser is never heard at the Derby. Officials throughout the day call each entrant, "champ," since each got to Akron by being the champ of some local derby.)

The winner then waited until two other winners were available and the three drew for lanes in the next heat. K8UCN handled the lane assignment chores since enough other volunteers were available for radio duties. After drawing lanes, the winners and the cars were returned topside, where they waited for their next run.

If the Derby were to run smoothly, action had to take place simultaneously at topside, the starting line, the finish line, and the runout area. Safety was the first concern, and an amateur radio operator was stationed at each location. They were coordinated by WB8DJP, operated by WD8CVH and WB8CBO. The control station was located on the second level of the bridge at the finish line and just behind the announcer so that information could be passed on to the crowd quickly.

In addition, a telephone line connected each station, and, leaving nothing to chance, another heat was not run until each point had given the okay. In addition to radio and telephone communications, a system of red and green lights and red and green flags was used. No car could leave the starting line until a verbal go ahead had been given and both the green light and green flag were visible.

Fortunately, this year there was no serious emergency to test communications capabilities. The few entrants who brushed the wall walked away and shed tears more from the agony of defeat than from any injury. The Akron Fire Department Emergency Medical Team and a US Army Reserve medical team careful-

K8VAK, who provided aerial communication for the skydiving exhibition, has his chute adjusted. Bruce used both 2-meter and 220 handhelds.

K8UCN coordinated lane selections as each heat winner arrived in the runout area. In the background is the Goodyear Air Dock, the largest building without interior supports.

WB8YNX and KB8CJ provided radio communication in the runout area.

ly examined the few champs who bumped the wall. The only damages were to the pride of the youngsters, some of whom had traveled many miles to represent their hometowns and countries. The race included champs from Germany, Venezuela, and Canada.

Other hams working Derby day included Clyde Lorenz WB8YNX, Jeff Ruoff N8BFU, and Tom Haynes KB8CJ (who were stationed in the runout area), Paul Banquer WD8MDC, who was at the finish line, and Bob Cronauer N8AHJ, Ken Langford WD8QWD, and WD8DAI, who provided communications for various Derby officials.

Bruce Rodenkirch WB8WFD shadowed the NBC crew which taped segments of the race for use during October on the new series "Games People Play." Bill Hessler W8DXT provided communications for Kazumi Hotai and his Tokyo television crew which was shooting footage for a special program on children of the world.

Ken Slezak N8BYS, who was stationed halfway down the track, had the most uneventful post. His only action was to check on an entrant who had applied his brake and stopped in the middle of the track after a shroud on his car loosened and blocked his vision.

It's not possible to name all the hams who helped during the week with the Derby or who might have helped give directions on Derby day on the other repeaters in the Akron area. Nor is it possible to mention all the clubs which were

represented by the people participating. But it is possible to tell a little more about the ham who helped make it all possible, Jim Ott KB8CT.

In the fall of 1972, Chevrolet officials (who had first sponsored the Derby in 1936) decided to withdraw their sponsorship. The Derby was sponsored by local groups until the fall of 1975 when another national sponsor was found. Novar Electronics of Barberton, an Akron suburb, pledged $165,000 toward the next Derby, and has supported each Derby since.

Ott, who was first licensed in 1962 as K8CAA, founded Novar when he was 17. (Novar stands for Northern Ohio Video and Radio.) Ott had gone to Ohio State University to study electrical engineering. While working with a deaf student there, he developed the Whisperlite, a device which converts sounds into light. When commercial interest in the device developed, Ott quit school and founded his company which, today, is a recognized leader in security systems including a new identification system which uses the vibrations created by the human body.

Though the Novar name is prominent during Derby week, on T-shirts and other Derby promotional materials, Ott does not make commercial use of his sponsorship during the rest of the year.

On race day, he said, "It's fun to be here seeing the kids enjoying themselves. This is a great program and I'm happy to be able to contribute."

Jim said that his work doesn't give him as much time on the air as he would like, but if you do hear KB8CT, jump in and say hello to a ham who helped make August 16 an important day to 91 champs. ■

KB8CT waves home the final heat of the 1980 All-American Soap Box Derby. Dan Purol of California, in the red car, took home a $5000 scholarship and a California Replicar kit in addition to the trophy.

KB8CT presents the senior division All-American Derby trophy to Dan Purol of Fair Oak, California.

Perfect Parabolas

—use some solar technology on your next dish antenna

I became interested in building an MDS TV converter after reading an article in the August, 1979, issue of *73 Magazine* entitled "You Can Watch Those Secret TV Channels."

After building the converter and coffee-can feedhorn, I was concerned over the number of trees between my location and that of the MDS transmitting station. A line-of-sight path is normally required at the frequencies used for MDS TV and trees greatly attenuate signals. I suspected that I would need an antenna with more gain than that of the "snow-saucer" type.

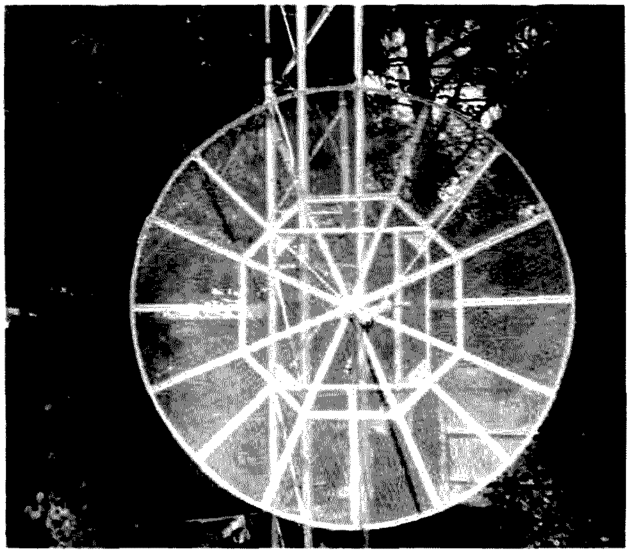

Photo A. Front view of completed four-foot dish showing rib structure.

Whenever UHF or microwave frequencies are mentioned, I form a mental image of a parabolic dish. However, they *are* expensive and I knew nothing about designing or building them. So what do I do now?

Research

After a long and fruitless search through my limited library of radio publications, I was ready to give up when I spotted my *Solar Energy Handbook*. It contains information on collecting light waves with parabolic reflectors. Having read that the properties of high frequency radio waves and light waves are similar, I decided to design and build a parabolic reflector based upon the information in the book. This information is shown in Figs. 1(a), 1(b), and 1(c) and illustrates three approaches that can be used to produce a parabolic curve.

Design materials needed are:

- Several sheets of linear graph paper
- Straightedge or ruler
- Compass for drawing circles
- Pencil
- Piece of wood—1" × 6" × 24"
- Approximately 5' of string
- 4' × 4' piece of plywood or heavy cardboard

Dimensions

Due to my limited knowledge, my choice of dimensions was based upon common sense and convenience. Choosing a diameter of four feet for high gain and a focal length of 26 inches so the feedhorn mounting tube could be short and rigid, I followed the instructions shown in Fig. 1(a). I let each square on the graph paper represent one inch (not shown for purposes of clarity).

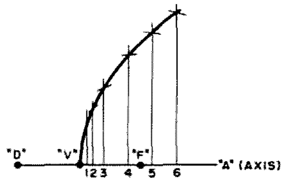

Fig. 1(a). If vertex "V" and focus "F" are given on axis "A", mark point "D" so that "DV" = "VF". Draw lines perpendicular to the axis at any points, 1, 2, 3, 4, 5, etc. Bisect each with an arc drawn from "F", with a radius equal to the distance of the particular point from "D". Thus, bisect line 3 with radius "D3" drawn from "F".

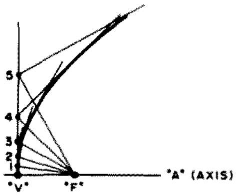

Fig. 1(b). If, as in 1(a), vertex "V" and focus "F" are given on axis "A", draw line from "V" perpendicular to axis. Mark any point on this line (1, 2, 3, etc.) and connect it to "F". Draw a line from each point at right angles to the line to "F". (Thus, from point 5, draw line at right angles to "5F".) Each of these lines will be a tangent of the parabola, which must be drawn inside these tangents, touching each section at its center.

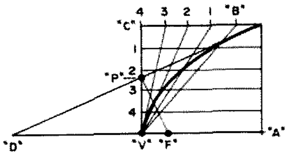

Fig. 1(c). If vertex "V" and axis "VA" are given as well as width "BA", draw "CB" parallel to axis and "CV" perpendicular to axis. Divide both into an equal number of equal sections (1, 2, 3, 4, etc.). Connect "V" to each point of "CB" (radial lines). Intersect each radial line with parallels drawn from corresponding points of "CV". The intersections are points of the parabola. Mark point "D" on extension of the axis so that "DV" = "VA". The line connecting "D" with "B" is a tangent at "B". Where "DB" intersects "CV", mark point "P". Draw line from "P" at right angles to "BD"; this will determine the position of focus, "F", on the axis.

After marking the graph, it is necessary to obtain a full scale graph. This is accomplished by drawing vertical and horizontal lines 1" apart for the full length and width of the 1" × 6" × 24" board. Having done this, observe the markings on your graph paper and mark the corresponding points on the 1" squares on the board. If you draw a line from point to point on the board, you will have a full-scale pattern on the board for forming the ribs of the dish. See Fig. 2.

Attach the 5' length of string to the center of the 4' × 4' plywood and, holding the pencil tightly against the string, draw a four-foot diameter circle on the plywood. This is your "rim" pattern. A complete list of materials is provided in the Construction Materials box.

Construction Details

Cut eight 22½" pieces of "Tee" metal and bend each of these so the flat surface will conform to the pattern on the wood graph. Be accurate because these 8 pieces are the ribs which establish the curvature of the dish. Refer to Fig. 3 for the following assembly steps.

Position the most curved end of the ribs in 1" from the outer edge of the pipe flange. Attach these eight ribs so the flat side will be against the bottom of the flange and will radiate outwardly with equal spacing. This should form a hub with eight spokes.

Keeping the flat side outward, carefully bend a length of the Tee metal around a large round object such as a 55-gallon oil drum and make a four-foot circle to match the circle on the plywood pattern. Using flat strap aluminum as a backing plate, attach the ends of this circle to form a 4' hoop or rim.

Attach the rim to the top of the eight ribs. Measure in 12" from the rim and attach eight pieces of Tee metal braces between the ribs to form an octagon-shaped circle on the rear of the dish. Attach eight more pieces of the Tee metal from the octagon-shaped circle to the rim, centered between each of the main ribs. See Fig. 3(d).

Dish Support

The dish supporting and mounting frame is made by making an 19" × 19" square with Tee metal. See Fig. 4. Each corner is braced with a 16-gauge triangle cut from the 4" × 4" sheet of aluminum. The frame is attached to the rear of the dish with 5" lengths of Tee metal. Additional braces from the frame to the dish are formed with the four 16-gauge 1" × 6" aluminum strips.

The two ½" × 8" aluminum strips are formed around one leg of the tower and will bolt to the rear, flat surface of the frame when the dish is mounted on the tower.

The 7/8" o.d. tubing, 3" long, is slipped over the ¾" × 19" aluminum tubing and the 19" tubing is attached to the upper and lower frame members. The 7/8" U-bolt clamps the 7/8" sleeve to the ½" × 23" aluminum tubing which will form the adjusting arm for the dish. This 23" length of tubing is inserted through a clamping bracket which is attached to another leg of the tower.

Covering the Frame

Using ¼" mesh wire (hardware cloth) or aluminum window screen, cut four pie-shaped wedges and attach them with bare aluminum wire to the ribs of the dish. The "tie wires" are bent into a U shape and inserted through the mesh over the braces. They are spaced at 2" intervals. This causes the mesh to closely follow the curvature of the ribs when the wire is twisted. For a neater appearance, you may wish to spray the entire assembly with aluminum paint as I did.

Testing

After construction came

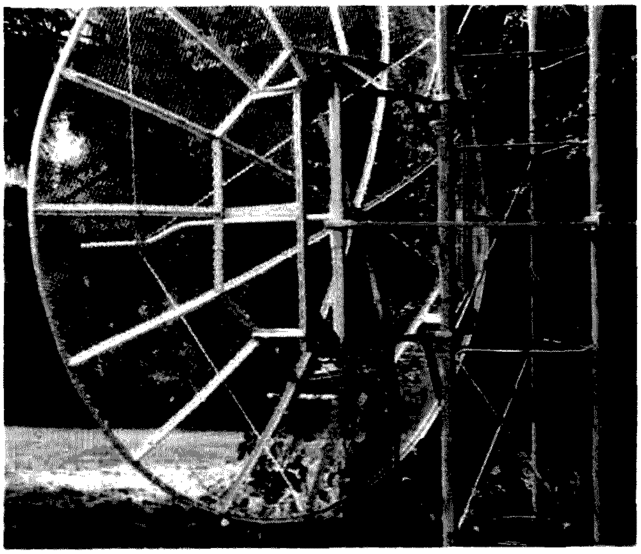

Photo B. Rear view of dish showing mounting details.

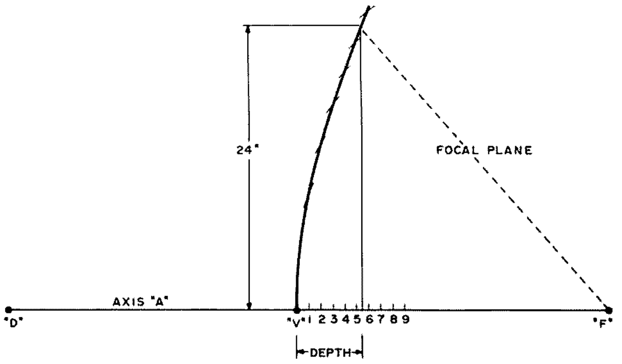

Fig. 2. Details for making full-size construction pattern (top half of the parabola graph).

Construction Materials

½" × ½" × ½" Tee-shaped aluminum strips
Small nuts and bolts or "pop rivets"
3-inch pipe flange
¼" mesh wire (hardware cloth) or aluminum window screen—enough to cover the reflector.
Aluminum tubing, ¾" o.d. × 19" long
Aluminum tubing, 7/8" o.d. (¾" i.d.) × 3" long
Aluminum sheet, 16-gauge, 4" × 4"
Aluminum strips (2), ½" wide × 8" long
Aluminum strips (4), 16-gauge, 1" × 6"
Aluminum strip, 16-gauge, 1" × 2¼"
Aluminum tubing, ½" × 36"
Aluminum tubing, ½" × 23"
1 U-bolt clamp (to fit 7/8" pipe)
1 U-bolt clamp (to fit tower leg)
Several feet of aluminum wire (clothesline wire), small gauge

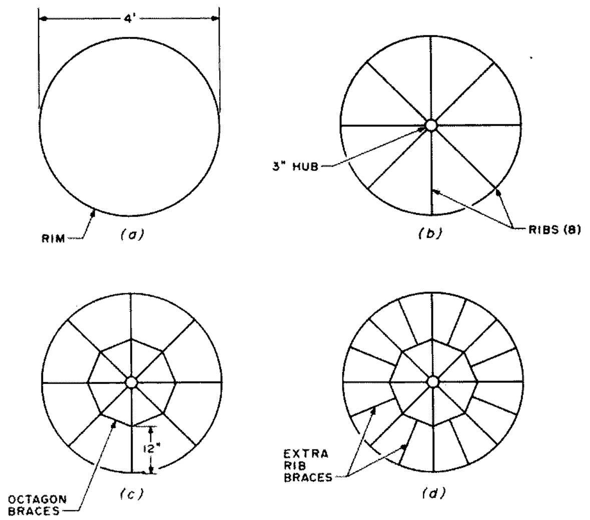

Fig. 3. (a) Rim dimensions. (b) Spoke installation. (c) Octagonal bracing placement. (d) Installation of extra rib braces.

the pleasure of testing something that worked right the first try. I was fortunate enough to have a Gunn diode oscillator operating at 10.5 GHz and the waveguide-horn from an old police radar detector. The Gunn oscillator was set up facing the waveguide detector at a distance of ten feet and the meter reading was noted. The Gunn oscillator was then pointed at the mouth of the dish, and by standing to one side and moving the detector around, I was able to locate the point of highest rf concentration. This point was 26½" from the vertex of the dish, only a half-inch off the design and now the meter read full scale (100 microamperes). This was much greater than the direct reading without the dish, indicating a great deal of gain.

The Gunn oscillator was then moved to a point three feet from the front of the dish and the detector was used at the rear of the dish to check for rf leakage through the mesh cover. None could be detected. This would seem to indicate that spacings greater than ¼" could be used for frequencies below 10.5 GHz.

Miscellaneous

The pipe-flange center hub makes horn attachment easy. You may wish to thread a short pipe nipple into the flange and slide a piece of aluminum tubing or PVC plastic over the nipple to mount the horn. You can clamp the two together with screw-type pipe clamps or hose clamps.

Conclusion

If you should build a parabolic reflector from the solar book information given, I believe that you will be well pleased with the results. I certainly am. I have become so interested in the design of dishes that I have completely dropped the MDS project and I am presently contemplating a 12 footer for satellite reception. Good luck.■

Help for the HW-2036

—hum mods for Heath-equipped hams

Almost immediately after I put my Heathkit® HW-2036 on the air, two problems cropped up. First, there was a terrible hum on the transmit audio whenever I tried to work through a repeater, and second, the phono plug coax connector kept coming loose. Daunted but not defeated, I put the thing back on the bench and proceeded to dig into the problems with great exuberance.

If you live in an area that doesn't require a Private Line® (PL) for repeater access you may never have noticed the hum. But if you use PL you undoubtedly have been told that you have a noticeable—if not objectionable—hum on your signal. It's not humming because it doesn't know the words, it's humming because the injection level is simply too high. Unfortunately, Heath did not see fit to include a level adjustment. Enter modification #1.

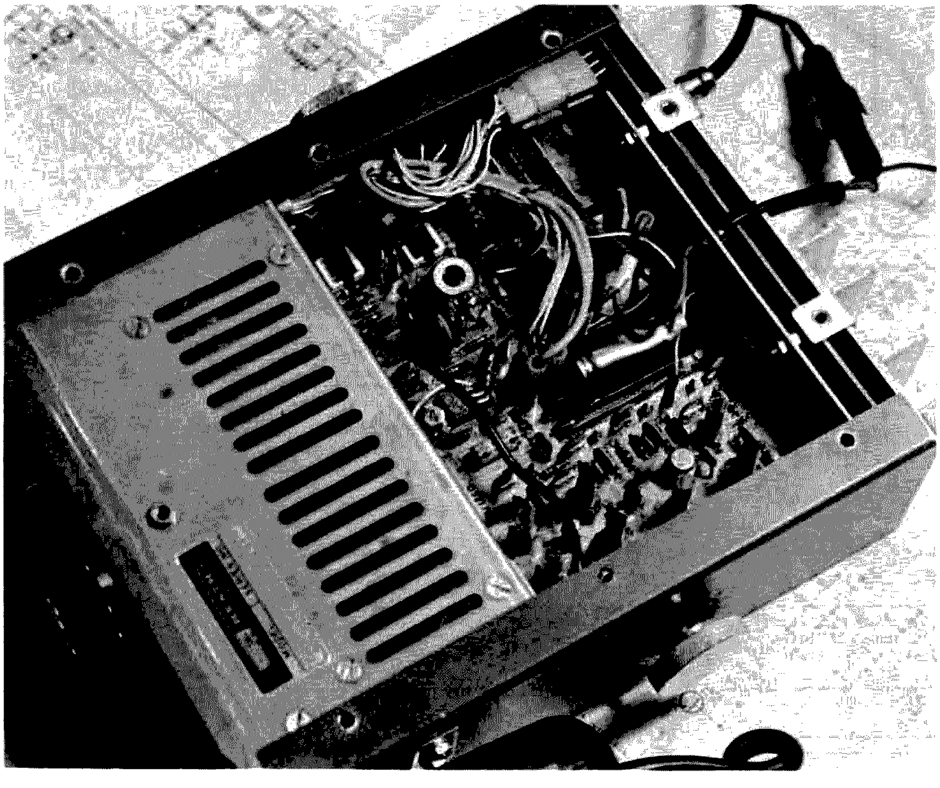

Photo A. This shows the completed modification. The PL adjustment pot is mounted horizontally behind the deviation pot. Note the coax pigtail at the antenna jack.

The square-wave output from the tone generator is fed through several stages of RC filtering to R134, a 470k resistor. (See Fig. 1.) Although R134 is part of the waveshaping network, its actual value does not appear to be critical. Replace it with a pot and you'll have a tone level adjustment.

In my first attempt at this mod, I used a 750k pot—and promptly ran out of adjustment range! A second trip to the junk box produced a 2.5-meg linear PC board pot that worked very well. Actually, any value from 1 to 5 meg will work. The lower the value, the easier it is to adjust—but the more you risk running out of adjustment room.

To prepare the pot, first

solder one end terminal and the arm together. Then solder about 3/4-inch lengths of wire to each end terminal. Bend the leads straight back from the front of the pot and set it aside for a few moments.

Pull the bottom cover off the rig to expose the transmitter circuit board. R134 is located behind the deviation pot. (See Fig. 2.) Snip the resistor in half, crush the carbon and composition from the leads, and bend the leads straight up. Now solder the leads from the pot to the leads protruding from the circuit board. Be careful—not too much heat—you don't want the solder to flow on the foil side of the board.

To adjust the pot, set it for about 500k and get into a QSO on a PL-controlled repeater. Slightly increase the resistance on each transmission. When the other stations report that they can no longer hear the tone, note the position, but continue increasing the resistance until you can no longer hold the machine. Then set the pot midway between those two points. If you find that you can no longer hold the machine while the tone is still audible, check the frequency of the tone.

As long as you have the rig on the bench, you may as well consider one other simple mod. My rig is in and out of the car several times a day. At that rate, it didn't take long for the phono plug coax connector to become loose and intermittent. After taking the rig apart several times to tighten up the connector, it finally dawned on me that there must be a better way.

One way would be to replace the phono jack with a chassis-mount BNC connector. That would require some (slight) mechanical rework of the box, however. Since my mechanical ability is zero—I can't even put the cap on a peanut butter jar without getting it cross-threaded—I began considering alternative solutions. I decided that a short piece of coax and a few connectors could do the trick.

For most practical purposes, the input and output characteristics of a half-wave section of coax are the same. If you were to solder a half-wave section of coax to the output of the rig, you would effectively move the output point to the end of the coax. That is the theory.

To put theory into practice, solder a UG-89/U BNC connector to one end of a piece of solid-dielectric RG-58. On the other end, solder a phono plug. The distance from the open end of the UG-89 to the tip of the phono plug should be 24-1/2 inches.

Now, tack solder the phono plug to the antenna connector on the rig. I emphasize *tack solder*, because you may eventually have to take the rig apart for maintenance, and a completely soldered connection would be a bear to get apart.

Replace the phone plugs in your car or shack, or wherever else you operate, with UG-88/U connectors; you'll be back in business without intermittent coax connectors.

There are several other mods which I would like to describe in future articles. In the meantime, you can enjoy operation without intermittent coax connectors and without the hum.■

The Honeymoon is Over

—hints and kinks for ham husbands

Let me tell you the tale of K9CNC and how he turned a YL into an X-XYL through the marvels of amateur radio.

A bright and shining boy was he, happy in love with his bride-to-be, and an eager radio amateur, as well. He never thought to tell the love of his life much about his involvement with radio, thinking that, most likely, she wouldn't be all that interested.

Came the wedding day and the honeymoon, and our happy lad drove up in the new family car, now completely outfitted with an Atlas 210X and a Hustler whip antenna. The new Mrs. was taken aback.

"... and what's that thing sticking out of the trunk?" she asked.

He explained with boyish innocence that it is for radio contacts, and that as they drive north on their wedding trip, he should be able to pick up ham operators in parts of the world he could never contact before.

"What's the matter?" she asked somewhat subdued. "Don't you want to talk to me?"

Well, they were off. Somewhere along the Florida turnpike he picked up Australia. As they reached Georgia, British Columbia was 20 over 9.

"Just sitting here with my XYL, driving up to New York City and watching the stars come out," he purred contentedly to a CQer from Pago Pago.

"What's an XYL?" the new bride asked from her forgotten corner of the front seat. You see, she had expected a bit more snuggling and a lot less conversation from parts unknown.

"Oh, that's you ... my ex-young lady," he threw off casually in her direction as he monitored a group of rag-chewers from Maine, Massachusetts, and Guantanamo Bay.

This came as a bit of a shock to the poor girl. Only this morning she was a young lady, and now she found herself over the hill. A doubletake to the bright, gold band and the first shreds of doubt began to bloom: a bride in the morning and a ham widow by dark.

Slowly our little bride came to hate the squawking little black box and to look on with embarrassment and discomfort when the antenna worked itself loose and tangled up traffic, as it frequently did. The honeymoon was over. Quickly.

Moving in to the new QTH only added to our XYL's joys. Where was her OM? Helping to carry the packing crates upstairs, deciding where to put Aunt Mary's lamp, or adjusting the water heater? 'Course not. He was hanging by his heels out their 9th floor apartment window, making the final arrangements on his dipole.

"My heavens," she breathed. She would really be a ham widow if he wasn't more careful. He survived sufficiently, however, to commandeer her best table for his transceiver, meters, and tools, smiling as he placed Aunt Mary's lamp in the perfect position to properly light his log and happily scattering his QSL cards decoratively over her new wallpaper. He got his shack in order long before he tapped the first nail in the wall to hang the wedding pictures.

Life went on for the XYL and her OM. He came home from the office, kissed the little woman hello, and headed for the shack. "K9CNC here on schedule," while the dinner got cold and the XYL began a slow burn. One day she had had enough. She left the ring on his QSL cards, murmured a quick 88, pulled the plug, and QSTed.

How to Keep Your XYL from Becoming an X-XYL

Poor K9CNC was a sorry case, indeed. Radio wasn't the only cause for his problems, but it was a contributing factor. It is an acknowledged fact that a radio operator can appear to be a strange breed of cat, especially to a wife who has no personal involvement with the romance of the airways, except to watch the back of her husband as he hunches over his CW key or ragchews with a DX station she can't hear herself and wonder *why?* You can be certain she would much prefer that he be romancing her ... or at least *talking* to her.

There are a lot of women who have become resigned to being ham widows. They've gotten accustomed

to watching the food get cold on the dinner table while they nag at their microphone-mouthed maniacs, or while they stand by the door, waiting for their Good-Samaritan husbands to finish that last, never-ending phone patch, as the concert starts without them or the shopping center closes for the night.

As an XYL myself, I can vouch that tolerance and understanding did not come easy. It took until I became a radio amateur to come to understand the ties that bind the enthusiastic ham. You don't have to turn your wife into an Extra-class operator to make life more livable, but with a few reminders, you might just be able to turn off (instead of tuning out) her long-suffering sighs, give her a greater appreciation for your hobby, and turn her on to the magic of radio for herself. Be careful, now. Don't be too good at this or you might find yourself a ham widower.

Introduce Her To the Hobby

Don't lecture, but do make it a part of your daily conversations to fit in explanations about simple electronics, history statistics, and/or the motivations that make for a radio amateur. She will become a more understanding part of your world when you share it with her.

Explain It To Her

If you are a serious ham and enjoy spending time with the rig, explain that from the onset. Tell her it is a hobby you enjoy, have long cultivated, and from which you take great pleasure. She'll appreciate the pastime more if she understands what you went through to master the code and pass those exams and sacrificed to construct or purchase the equipment. If she is new to the game, she is going to be doing a lot of wondering, as she sits alone watching TV or reading a book, as to why you have so much to say to strangers and nothing to say to her.

Explain the Lingo

Don't offhandedly throw out an explanation (as K9CNC did) that XYL means ex-young lady, without cushioning the blow. When you know nothing about the jargon, a young lady is one thing, while an ex-young lady is something else again. Don't rattle off abbreviations she couldn't possibly have any background knowledge about, as you spin your dials and rotate your antenna. Take the time to *stop*, give her your full attention, and answer her questions, no matter how simple or how complex. She'll retain information presented this way, believe me. It seems one of the great complaints from non-hams is their failure to understand what is being said. It turns them right off.

Don't Be Condescending

If you are going to try to make your hobby understandable to a wife who has difficulty plugging in the toaster or setting the clock, don't lecture as if you didn't expect her to understand. Again: Answer her questions. Explain a point as many times as it takes, if she is interested . . . but *don't* get angry at her if she still doesn't understand. After all, it is not her hobby: It's yours. She might pleasantly surprise you someday with her knowledge, as she proudly shows off your shack and finds she can speak intelligently about the operation of your Yaesu, Kenwood, or Swan.

Never Put Your Shack Before the Needs of the Household

Even the most unmathematical of wives can quickly calculate the difference between the time it takes for you to run down to Radio Shack when you need a new connector or a piece of 75-Ohm coax and how long it takes for you to take out the trash, get around to mowing the lawn, or to bring home a new stopper for the sink.

Make the Shack a Welcome Place

Just because the little woman is not an electronic wizard, she *can* be trusted within 10 feet of your equipment. If she moves your dials or misarranges your meters or tools, don't jump at her. Instead, use the incident as a way to continue your introductory course in electronics. Make the shack and your equipment comfortable, interesting, and familiar to be around. Turn the shack into a place where she can come and *talk* to you as well as a place where you go to talk to your fellow aficionados. When she brings you that needed cup of coffee, occasionally ask her to pour one for herself and join you. Show her the same courtesies you show to your fellow hams on the air.

Don't Let the Hobby Get Out of Hand

Don't turn every available space like the backyard, garage, or spare room into a graveyard for electronic equipment. It's easy to become a collector, but keep it within reason, and keep it neat.

Encourage Her Interest in Radio

If your XYL gets bitten by the radio bug, become her teacher, or point her in the right direction toward a course of study. You'll have a partner in the shack, a worthwhile experience to share, and a little woman who can appreciate your true meanings when you tell your fellow amateurs you've got an XYL that's 40 over 9. That's some Young Lady. ■

Rx for a Bad Day

Is it one of those dull gloomy days when even the birds are walking, and it's not a fit day to go out and put up that new sloper or inverted vee antenna you wanted to try? DX isn't coming through yet because the MUF isn't right, some jerk squirrel keeps kerchunking the repeater or plays tunes on the Touchtone™ so that two meters isn't fun. Maybe the wind played havoc with your beam last night and now it looks like a limp pretzel or some modern art object, or maybe your rig blew up in the middle of a QSO or just before that sked with a rare station in some far off land.

Any fool knows all these things aren't going to happen to you at once. But if it is 'one of those days' maybe you can just forget the whole mess and brighten your and someone else's day a little by taking some time to think of a fellow ham you admire and respect to nominate for Dayton's "Amateur of the Year Award" for 1981. No, it's not too early to think about it. It does take a little time and effort to nominate some one for "Amateur of the Year."

What is the stature of this individual that we seek for recognition each year at Dayton?

First, he or she will be a well-respected person in the community; a leader, not only in amateur radio activity, but in civic activity as well. He will probably be licensed for at least 10 years or more for it is long term overall excellence in amateur radio that we are looking for.

His contribution to amateur radio may be in any of the hobby related areas. Possibly his greatest contribution is in the engineering field of our hobby, or his expertise may be in antenna design, some new type of modulation or an improvement to existing design, etc. Maybe he has contributed greatly to improvement of amateur regulations or possibly his contribution is the legal field of our hobby, a very important one these days. Get the idea? In short, an outstanding individual and amateur.

In 1974, another award was established, the "Special Achievement Award." This award is just what it would seem to be — an award for one-time special event or specialized activity by an amateur or group of amateurs. This activity may be in the engineering field — QRP — DXpeditions —net activity — emergency work or any one-time outstanding activity related to the amateur radio hobby.

Nominees for both of these awards may be from anywhere in the world, not just the U.S.A.

So! Don't just sit back and say, "Gee!, somebody ought to nominate that guy for "Amateur of the Year." Don't wait for George to do it. Give us all the details you can gather, especially activities that are directly attributable to him or her.

All nominations are carefully reviewed and are saved from one year to the next for future consideration and to allow some nominees to develop to their full potential. All nominations are considered for both awards, and the awards will be presented at the 1981 HAMVENTION Banquet.

So, have you nominated some one in the past? You may want to renominate him with update on recent activities or just send in update information on his latest accomplishments.

Do it now! Besides you may win a set of free tickets to the "HAMVENTION" for your nominee and yourself.

For more information or nomination blanks (not mandatory) write to the address below:

CB to 10

—part XXX: the Midland 13-866

The basic applications of this conversion will apply to most CB chassis using the 23-MHz series of crystals. The chief difficulty with this radio, which uses no crystal trimmers, is to figure the pF load for the crystals needed. The load of the circuit is about 58-60 pF, but since the crystals are third-overtone cut, the load to request is about 22 pF cut for third overtone operation. There are two methods of approaching this chassis, but changing the 23-MHz crystals is recommended. The formula is simple: Just add 2 MHz to the existing crystals.

The crystals required are: 25.290, 25.340, 25.390, 25.440, 25.490, 25.540.

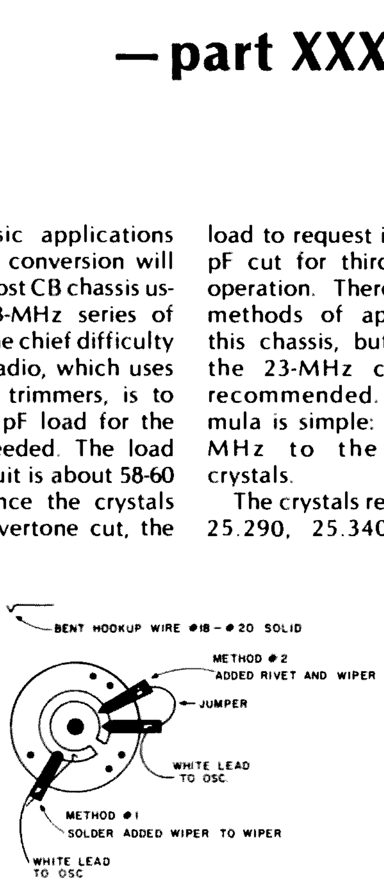

Fig. 1. Two methods of activating position 24 on the channel selector.

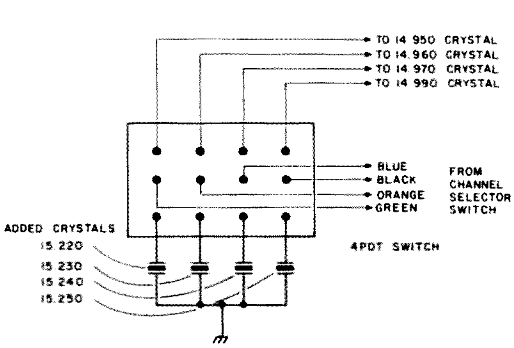

Fig. 2. Adding 24 extra channels to the Midland 13-866.

Changing these crystals is simpler on an initial conversion because their fundamental range is only 8 MHz, and they are far easier to work with than fundamental 16 MHz crystals. In addition, it is possible to add 24 more channels to the synthesizer circuit by use of a 4PDT switch and four more crystals. Frequencies needed are: 15.220, 15.230, 15.240, and 15.250 MHz, which are stock items at most crystal houses, and range in price from $3.50 to $6.00 each (so shop around).

Activating the channel 24 position can be accomplished by locating the white wire coming from the selector switch and going to TR6. Using a piece of hookup wire, as diagramed, or a spare wiper from an old rotary switch, solder it to this terminal in such a way that it makes contact with the switch when the defeat cut in the switch meets the normal wiper. (Refer to Fig. 1.)

Install the new 25-MHz crystals in place of the ones removed from the circuit board. Apply power to the set, and with a frequency counter check for oscillation at the collector of TR6. If the oscillator is not functioning, back out the slug on T6 until the circuit fires. With TR6 oscillating, you now can proceed with the tune-up procedure.

Connect a signal generator through a .01-uF capacitor to the base of TR17. Ground the generator to chassis ground, not the case. With the set on channel 13, (23 if you are installing the 15-MHz crystals as well), inject a 29.115-MHz signal with 1000 Hz, 30% modulation (29.255 MHz for channel 23). Adjust T12, T13, T14, and T15 for maximum receiver output.

Key the transmitter into a dummy load with a wattmeter connected and tune T1 through T9 for maximum rf output. The relative output function of the S-meter may be used for this initial tune-up. Then peak C24 and L5 for maximum power output. At this point, you should have about 2- to 2.5-Watts output. The value of the tank coils in these sets varies greatly, and it may be found that maximum power output occurs when the L5 slug is all the way out. If this is the case, replace C22 (150-pF capacitor) with a 100-pF ceramic disc. This will allow the coil to tune over its mid-range and increase power output to about 5 to 6 Watts. Modula-

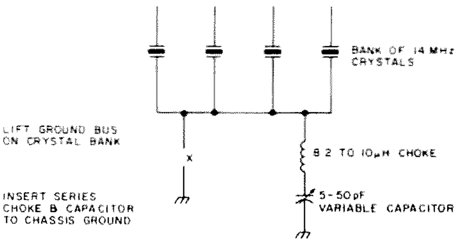

Fig. 3. VXO operation with the Midland 13-866.

tion can be increased by removing TR8 from the circuit.

Adding additional channels by using a 4PDT switch is accomplished by removing the green, orange, blue, and black leads going from the selector switch to the 14-MHz crystals on the chassis. Connect these wires as diagramed in Fig. 2. With the switch down, the 24 low channels will be obtained. With the switch in the up position, the upper range can be used.

For frequencies other than, or in addition to, the normal *73* band plan, the basic conversion has a usable range of about 800 kHz without retuning.

VXO operation with this radio can be obtained by lifting the ground bus of the 14-MHz crystals and inserting a 10-uH choke and a 5-50-pF variable capacitor in series with the crystal bus to chassis ground, as in Fig. 3. This trick will work with any fundamental crystals up to about 16 MHz. Do not attempt to use it on crystals operating in the overtone mode because severe instability will result. ■

The Nicad Conditioner

—help your nicads lose their memories

Mitchel Katz W2KPE
147-11 76th Avenue
Flushing NY 11367

Quite a few nicad battery-charger circuits have appeared in print lately. However, as none of the circuits would fill my requirements, considerable research and planning was done before starting on this project. Most of the chargers described in articles were for the preferred constant-current method. Others used the constant-potential system. Still others used a combination of both. Each of the articles detailed the advantages of its method, but neglected to mention the disadvantages. Let us look briefly into each of the systems mentioned.

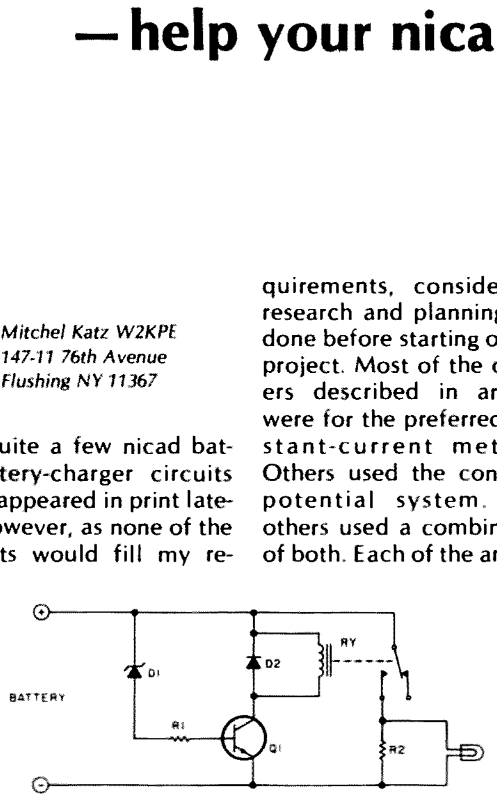

Fig. 1. Conditioner circuit.

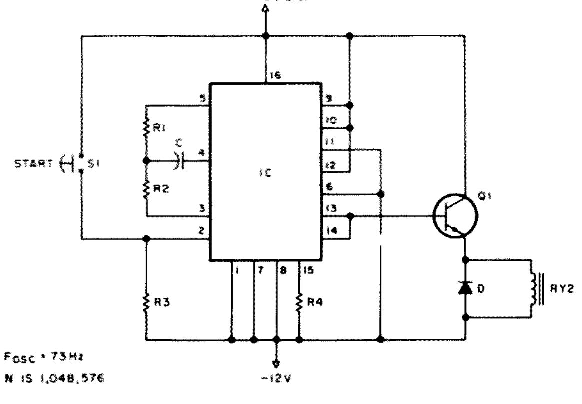

Fig. 2. Timer circuit.

Constant-current charging is usually done at the 10-hour or .1C rate (C is the rated capacity of the battery). This is fine, except that it takes from 14 to 16 hours for a full charge—an awful long time to be without your HT! Some of the newer chargers use constant-current charging at the .3C rate so that full charge can be obtained in as little as four hours. Remember that we must replace between 130% to 150% of the battery capacity due to inefficiencies in charging. This is a step in the right direction, but we must be careful about overheating as this can ruin the cells.

Constant-potential charging is definitely not recommended. With this method, the charge would start out at quite a high level, resulting in some heat being generated within the cells. As we approach the overcharge condition, additional heat will start to build up. As the battery heats up, the cell voltages will decrease somewhat, leading to even more overcharge current and greater heat buildup. This is called thermal runaway, which will eventually destroy the cells. Because of this problem, constant-potential charging is generally not recommended. The voltage cannot be set low enough to prevent thermal runaway and still fully charge the cells.

Combinations of constant-current and constant-potential systems have also been described. These systems charge the battery at perhaps the .3C or an even higher rate. A voltage sensor is provided so that when the battery reaches some predetermined level, the constant-potential method will take over. The voltage here can be set to hold additional charging current to a suitable value. One drawback to this system, however, is that cell voltages can vary with repetitive charges. It can also vary with ambient temperature. Then, of course, suppose the battery develops a shorted

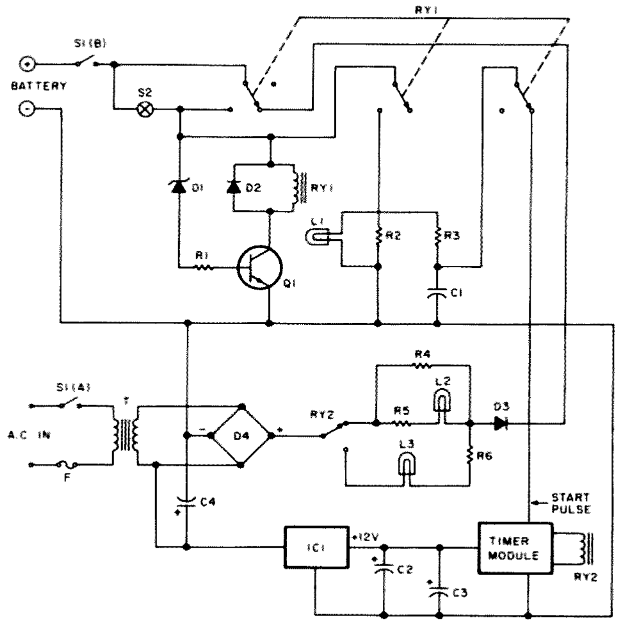

Fig. 3. Circuit for complete conditioner/charger.

cell. All of these problems mentioned will prevent the battery from reaching the sensor cutoff, so that high-rate charging can continue, eventually damaging the battery.

At this point, let me digress. Some experimenters and suppliers of chargers believe that the charge should be terminated after replacing 130% to 150% of the battery capacity. This is to prevent losing electrolyte within the cells. Others prefer the battery to remain on a trickle charge which may be as low as .01C of the battery capacity. General Electric Company's *Nickel Cadmium Battery Handbook* recommends that nicad batteries be charged at a fairly high rate, but that at completion of the normal charging period they be kept on a .1C-rate topping charge. As all cells in the battery may not have identical characteristics, the topping charge will permit the weaker cells to get a full charge without harming the other cells. G.E. goes on to say that most nicads may be left on the .1C charge rate for extended periods of time without harm.

Another item worth mentioning here is the memory effect of nicads, but since we are all probably aware of this condition by now, no discussion should be necessary.

Evolution of the Conditioner/Charger

Very few chargers described in magazine articles or that are available from the HT manufacturers take into consideration the state of charge remaining in the nicad battery. If the battery is not depleted when put into the charger, this can lead toward developing the memory effect just mentioned. To prevent this from happening, the conditioner shown in Fig. 1 was developed. This can be built as a stand-alone unit or may be incorporated into a complete charger system. Before the battery is placed on charge, it is put into the conditioner. It will immediately go into discharge at the 1C rate. When the battery voltage drops to the 1-volt-per-cell cutoff point, the relay will drop out, thereby terminating any further discharge. This procedure will not harm the battery and it will erase any memory effects.

Parts List for Fig. 1

D1—Zener diode (1 V per cells in battery)
D2—Silicon diode
R1—1000 Ohms, ½ Watt
R2—75 Ohms, 10 Watts
RY—Coil rated at less than battery voltage
Q1—Motorola HEP S0038
Lamp is type 387 in suitable holder.

Parts List for Fig. 2

IC—HEP C4058P programmable timer
Q1—HEP S0038 transistor
D—Silicon diode
RY—12-volt relay with dc coil resistance greater than 250 Ohms
R1—2700 Ohms, ¼ W
R2—6200 Ohms, ¼ W
R3—1 megohm, ¼ W
R4—10k, ¼ W
S1—Momentary contact push-button switch
C—2.2 uF, 35 V

Parts List for Fig. 3

T—Stancor P 6469, 25.2 V@1 A
F—1-A fuse
D1—Zener diode (1 V per cells in battery)
D2, 3—Silicon diodes
D4—1-A bridge rectifier
R1—1000 Ohms, ½ W
R2—75 Ohms, 10 W
R3—1000 Ohms, ½ W
R4—250 Ohms, 10 W
R5—430 Ohms, ½ W
R6—620 Ohms, ½ W
RY1—4PDT 12-volt coil (Allied Control TF 154C-C) (P and B KHU 17D11)
RY2—SPST 12-volt coil (greater than 250 Ohms)
S1—DPST toggle switch
S2—Momentary contact push-button-type switch
L1, 2, 3—Type 387 lamps in appropriate holders
C1—10 uF, 25 V
C2—4.7 uF, 35 V
C3—.47 uF, 35 V
C4—50 uF, 50 V
Q1, 2—Motorola HEP S0038
IC1—7812 regulator

Another advantage gained by this conditioning is more operating time per charge. In Fig. 1, the relay used should operate on a low current and have a coil rating somewhat lower than the battery voltage. Resistor R is chosen so that the total current drain on the battery, including the pilot light and relay, should total the Ampere-hour rating of your battery.

To describe the operation of the conditioner: When a battery which is not fully discharged and has greater than 1 volt per cell is connected, current will flow through the zener diode. This will place a positive bias on the base of the transistor, causing it to conduct. The relay is pulled in and the discharge cycle starts. When the battery voltage drops to the 1-volt-per-cell level, the zener diode stops conducting, cutting off the transistor. This causes the relay to drop out, terminating any further discharge.

The next consideration in the design of the charger was the method to be used. I wanted a constant current to charge at a fairly high rate. As it is necessary to replace about 130% of the battery capacity for a full charge, I decided to charge at the .5C rate for approximately two hours to replace 100% of the capacity. At the end of this time the charger should switch

automatically to the 1C rate to complete the charge, or for battery-topping.

Consideration was given to the control device. Some rapid-charge batteries have a thermistor built in. As the battery approaches full charge, the resistance of the thermistor will change, triggering the control device to reduce the charge rate. I found that the thermistor resistance would sometimes change. Then again, different manufacturers would use different thermistors. Sometimes they were different from battery to battery. This method, then, was discarded.

What was finally decided upon was a timer method of control. The Motorola 4058 Programmable Timer proved ideal, as it can be set for any time period desired. The circuit of the timer is shown in Fig. 2. Once the timer is triggered, the countdown begins. At the end of two hours, my timer operates, pulling in the relay for a low charge rate. This system has proven itself most reliable, with none of the defects listed for other charge-control methods. A copy of the 4058 application bulletin may be obtained by writing to Motorola, or I will send you a copy upon request and an SASE.

Fig. 3 shows the circuit of the complete conditioner/charger. Although the parts listed apply for use with my Motorola HT 220 Slimline using a 225-mAh rapid-charge battery, the same circuit can be applied to any other battery. Only a few resistors may have to be changed to vary the charging rates. The length of the high-rate charge time can be changed very easily by changing two or three jumper wires.

Several refinements were added, such as pilot lights to indicate the charger/conditioner status, discharge, high-rate charge, and low-rate charge. The power switch has been connected as a safety switch to prevent accidental battery discharge. A self-testing feature is also included. Before inserting the battery, turn on the power switch and press the start button. The discharge light and the high-rate charge indicator lamps should come on. Release the start button and both lamps will go out. If you press the start switch and the low-charge lamp comes on, shut off the power switch and then turn it on again.

Operation of the unit is extremely simple. Once you've checked the charger as described, connect it to the battery. The high-rate lamp should come on. Press the start button and the discharge lamp should come on. When the battery is down to 1 volt per cell, the high-rate charge lamp should come on again. This will now indicate that the battery is receiving its charge.

As soon as the battery goes into the charge mode, a pulse is sent to the timer to initiate the countdown. At the end of the scheduled period, the timer will pull in relay 2, shifting the charge to the low rate. High-rate charging was purposely limited to 100% return rather than 130% to prevent overheating of the cells.

This charger has now been in use for over a year, and it performs flawlessly. A fully automatic system at last! ■

HAM HELP

We are happy to provide Ham Help listings free, on a space-available basis. We are not happy when we have to take time away from other duties to decipher cryptic notes scrawled illegibly on dog-eared post cards and odd-sized scraps of paper. Please type or print (neatly!), double spaced, your request on an 8½" x 11" sheet of paper and use upper- and lowercase letters where appropriate. Also, please make a "1" look like a "1," not an "l," which could be an "el" or an "eye," and so on. Hard as it may be to believe, we are not familiar with every piece of equipment manufactured on Earth for the last 50 years! Thanks for your cooperation.

I am looking for instruction books or diagrams for Navy receivers R-516/URR-27 (VHF) and CNA-46188A/RBH-3, and for GE mobile (accent) 450-MHz model EG48ST8. Can anyone tell me how to extend the receiver frequency range of the KDK-2015A to cover more of the 140-to-150-MHz spectrum? I will pay reasonable prices.

Joel Jones W4JQB/7
PO Box 745
Airway Heights WA 99011

I need a schematic for an Eico model 427 oscilloscope. I will be glad to pay any copying costs.

Steve Stout KA5CRI/9
1537 Winslowe Dr. #1-B
Palatine IL 60067

Does anyone have an owner's manual for a Drake TR33-C 2m transceiver? If you do, I would like to copy it or pay you for a copy.

John Vercellino WB9OVV
4636 Pershing
Downers Grove IL 60515

Old-timer desperately needs service and operating manual with schematics for a Phasemaster II-B transmitter manufactured by Lakeshore Industries, Manitowoc, Wisconsin.

This old tube-type transmitter covers 160-10 meters and is capable of CW, PM, AM/DSB, or SSB emission. It has a vfo, a 1626 final amplifier, and utilizes a "tuning eye" tube as tuning indicator.

Will pay copying and mailing costs or will purchase manuals outright. Thank you.

Jaff Giesar KA7HHQ
19309 Winesap Road
Bothell WA 98011

I need a schematic and instruction manual for a Hallicrafters SR-46 6-meter transceiver. I will pay for these items (or for copies) or I can reproduce these documents and return originals. Thank you.

Theodore J. Cohen N4XX
8603 Conover Place
Alexandria VA 22308

I'm looking for an instruction manual and schematic for a Heathkit® IB-2 impedance bridge. I would like to copy and return but will pay copying costs. Thanks.

Gene Smarte WB6TOV
Nubanusit Road
Hancock NH 03449

I have an old military transmitter (World War II era), model BC-696A. It was part of the SCR-274N Command Set. I would like to get this rig working, but I'm in need of necessary info. If you have any manuals and schematics, I would deeply appreciate your help, and will pay any return postage.

Angelo Pepe
2330 Voorhies Ave., Apt. 6H
Brooklyn NY 11235

I need a schematic and/or operation manual for a Trio 2200-G 2m transceiver. I will pay for copy or copy and return original. Thanks.

Daniel H. Soares PY2TTP
PO Box 12113
Sao Paulo SP 01000
Brazil

I would like to contact anyone with technical information concerning the Regency Model ACT-W10 Whamo scanner receiver. This is the one with the "combs" for frequency selection. I need the theory of operation and alignment data. I will pay for postage, copy work, or information.

Wilbur T. Golson W5CD
1324 Marque Ann Dr.
Baton Rouge LA 70815

SOCIAL EVENTS

Listings in this column are provided free of charge on a space-available basis. The following information should be included in every announcement: sponsor, event, date, time, place, city, state, admission charge (if any), features, talk-in frequencies, and the name of whom to contact for further information. Announcements must be received two months prior to the month in which the event takes place. They should be sent directly to Editorial Offices, 73 Magazine, Pine Street, Peterborough NH 03458, Attn: Social Events.

MUSKEGON MI
APR 3-4

The Michigan Area Amateur Radio Council will sponsor the ARRL Michigan State Convention and Hamfest on April 3-4, 1981, at Muskegon Community College. On Friday evening, April 3rd, the "Ham Hospitality" room will be open to all at the Muskegon Holiday Inn. At 10:00 pm there will be a presentation and at midnight, an initiation. On Saturday, April 4th, doors and registration will open at 8:00 am at the college. An interesting ladies' program will be presented as well as many other events. Saturday tickets are $3.00 each, with no advance or mail ticket sales. Swap and shop table space may also be purchased on Saturday. Advanced registrations are required for the Saturday dinner program. Overnight reservations should be made directly. For additional information, write to MAARC, PO Box 691, Muskegon MI 49443, or contact Mr. Clarke Cooper K8BP, Convention Chairman, at (616)-865-6198.

ROCHESTER MN
APR 4

The Rochester Amateur Radio Club and the Rochester Repeater Society will sponsor the Rochester Area Hamfest on Saturday, April 4, 1981, at a new location, John Adams Junior High, 1525 NW 31 Street, Rochester MN. Doors will open at 8:30 am. There will be a large indoor flea market for radio and electronics items, prize raffles, refreshments, and plenty of free parking. Talk-in on 146.22/.82 (WRØAFT). For further information, contact RARC, WBØYEE, 2253 Nordic Ct. NW, Rochester MN 55901.

UPPER SADDLE RIVER NJ
APR 4

The Chestnut Ridge Radio Club will hold a ham radio and computer flea market on April 4, 1981, from 9:00 am to 3:00 pm at the Education Building, Saddle River Reformed Church, East Saddle River Road at Weiss Road, Upper Saddle River NJ. Tables will be available for $10; tailgating, $5. There is no admission fee. Food and drink will be available. For further information, contact Jack Meagher W2EHD, (201)-768-8360, or Nell Abitabilo WA2EZN, (201)-767-3575.

COLUMBIA MO
APR 4

The Central Missouri RA will present Columbia Hamfest '81 on April 4, 1981, at the Columbia Ramada Inn, Columbia MO. Admission will be $3.00 at the door and advance tickets are available for $3.00 each or 4 for $10.00. Prizes to be awarded include an Icom IC-2AT and a Kenwood TS-130S. Many commercial exhibitors will be present and a large, hard-surfaced tailgate area is available. Forums, association meetings, and XYL activities will round out the day. A banquet on Friday, April 3rd, at 7:30 pm at the Ramada Inn will feature a talk and question and answer period conducted by Mr. James Dalley, FCC Engineer-in-Charge, Midwest Region. An Icom IC-2AT will be given away at this banquet. Banquet reservations must be made in advance and the cost will be $14.00. Special group rates for overnighters will be made by the Ramada Inn. Talk-in on 146.76/.16 and 223.34/224.94. For tickets, information on reservations, available indoor flea-market space, etc., write to Columbia Hamfest '81, PO Box 283, Columbia MO 65201.

GOTEBORG SWEDEN
APR 4-5

The Goteborg Transmitting Amateurs invite all interested hams to an international ham meeting In the Swedish Trade Fair Centre, Goteborg, Sweden, on April 4-5, 1981. Featured will be a thematic stamp exhibition; lectures on VHF, UHF, and SHF; and meetings for YLs, award-hunters, and DXers. Other programs to be announced are fox-hunting, a mobile-radio contest, and a CW speed contest. A hamfest will be held on Saturday night.

PADUCAH KY
APR 5

The Paducah ARES Club will hold its 2nd annual ham/swapfest on Sunday, April 5, 1981, from 8:00 am to 5:00 pm, at the National Guard Armory, Paducah KY. There will be hourly as well as grand prize drawings. Dealers will be on hand. Talk-in on 147.66/.06 and 146.52. For additional information, contact Larry Reid AI4T, Chairman, 220 Longview Drive, Paducah KY 42001.

ST. CLAIR SHORES MI
APR 5

The South Eastern Michigan Amateur Radio Association will hold its Swap & Shop on April 5, 1981, at South Lake High School, St. Clair Shores MI. There will be a grand prize as well as hourly prizes. Ample parking will be available. For table space, write Robert Boudreau WD8RPQ, 27117 Shelbourne, Warren MI 48093, or phone (313)-754-1793.

PARAMUS NJ
APR 5

The Bergen ARA will hold a Ham Swap 'N Sell on April 5, 1981, at Bergen Community College, Paramus NJ. There are thousands of spaces available for tailgating only. Buyers are admitted free. Sellers must pay $3.00 and bring their own tables. For more information, contact Jim Greer KB2EI, 444 Berkshire Road, Ridgewood NJ 07450, or phone (201)-445-2855.

WEYMOUTH MA
APR 11

The South Shore Repeater Association will hold its fifth annual ham auction on April 11, 1981, at Central Junior High School, Broad Street, Weymouth MA. Check-in begins at 8:00 am and the auction starts at 12:00 noon. There will be a raffle with a Yaesu FT-207R HT as the grand prize, as well as many other small prizes during the auction. The winner need not be present to receive the grand prize. Minimum bids of 15% are allowed. Talk-in on 147.90/.30.

KANSAS CITY MO
APR 11-12

The PHD Amateur Radio Assn., Inc., will sponsor the 12th annual Northwest Missouri Hamfest and Missouri State ARRL Convention on Saturday and Sunday, April 11-12, 1981, at the Kansas City Trade Mart, Kansas City MO, from 9:30 am to 5:30 pm. The 1981 directory of all amateurs in the 20-county metropolitan Kansas City, Missouri/Kansas area will be on sale at the hamfest. Display booth spaces are available at a minimal cost of $40.00 for a single 10 × 12 booth, which includes 4 passes, security, electric hookups if needed, tables, chairs, and free parking. For an additional fee of $20.00, extra space (10 × 12) is available. Displays may be set up from

8:00 pm to 10:00 pm on Friday, April 10th, and from 7:00 am on Saturday, April 11th. For further information, contact L. Charles Miller WA0KUH, 7000 NE 120th, Kansas City MO 64166, (816)-781-7313, or Thomas L. Bishop K0TLM, 4936 N. Kansas, Kansas City MO 64119, (913)-342-4939.

FRAMINGHAM MA
APR 12

The Framingham Amateur Radio Association will hold its annual spring flea market on Sunday, April 12, 1981, at the Framingham Police Station drill shed, Framingham MA. Doors will open at 9:00 am and admission is $1.00. Sellers' tables are $7.00 in advance and $8.00 at the door. Talk-in on .75/.15 and .52. For more information or seller pre-registration, contact Ron Egalka K1YHM, 3 Driscoll Drive, Framingham MA 01701, or phone (617)-877-4520.

RALEIGH NC
APR 12

The Raleigh Amateur Radio Society is sponsoring its ninth annual hamfest on Sunday, April 12, 1981, at the Crabtree Valley Mall, US 70 West, Raleigh NC. Activities begin at 9:00 am. General admission is $3.50. There will be many prizes, including a first-prize choice of a Kenwood TS-130S HF transceiver and PS-30 12-volt power supply or an IC-251A multi-mode 2-meter transceiver with Mirage B-108 80-Watt amplifier. Second prize is a triband beam; third prize is a heavy-duty CDE rotor. The drawings will be held all day Sunday. A covered flea market will also be featured. There will be a hospitality room from 7:00 pm to 11:00 pm on Saturday. Talk-in on WR4ACF 146.04/146.64 and WR4AOE 146.28/146.88. For additional information or reservations, write to RARS Hamfest, PO Box 17124, Raleigh NC 27619.

WELLESLEY MA
APR 18

The Wellesley Amateur Radio Society will hold its annual auction on Saturday, April 18, 1981, beginning at 11:00 am, at the Wellesley High School Cafeteria, Rice Street, Wellesley MA. Doors will open at 10:00 am. Talk-in on .60/.03, .04/.64, and .52. For further information, contact Kevin P. Kelly WA1YHV, 7 Lawnwood Place, Charlestown MA 02129.

WAUKEGAN IL
APR 18

The Civil Air Patrol, Waukegan Squadron, will hold its first annual Spring Hamfest on April 18, 1981, from 0700 to 1700, at the Lake County Fairgrounds, IL Rte. 20 and US Rte. 45, Waukegan IL. The donation is $2.00 and tables are $1.50 on a first-come basis. Features will include a large indoor flea market, refreshments, and free parking. Talk-in on 146.94. For more information, call (312)-244-2134, or send an SASE to W9NXR, 637 Emerald, Mundelein IL 60060.

DAYTON OH
APR 24

The 12th annual B•A•S•H will be held on Friday night of the Dayton Hamvention, April 24, 1981, at the convention center, Main and Fifth Streets, Dayton OH. Parking is available in adjacent city garage. Admission is free to all. Sandwiches, snacks, and a COD bar will be available. Live entertainment will be provided. Awards include a new synthesized HT. For further information, contact the Miami Valley FM Association, PO Box 263, Dayton OH 45401.

SPOKANE WA
APR 25

The Inland Empire Amateur Clubs will sponsor a swapfest at the Floral Building at the Spokane Interstate Fairgrounds, Spokane WA, on Saturday, April 25, 1981, beginning at 9:00 am.

✓ Reader Service—see page 82

Admission and exhibit space are free. Flea market tables are \$5.00 per 4' × 8' table. Features include an auction, contests, raffles, old and new gear, a YL's corner, a snack bar, a Dixieland band, and commercial and non-commercial displays. Talk-in on 146.34/.94 and 146.52. For reservations for tables, exhibit space, and/or a free RV site (without electrical hookup), write Swap Fest, c/o Jan Thiemann KA7DDU, 7803 E. Mission, Spokane WA 99206.

MOUNT PLEASANT TX
APR 25

The Mount Pleasant High School Amateur Radio Club will sponsor an indoor swapfest on April 25, 1981, at the Mount Pleasant High School campus, Mount Pleasant TX. Doors will be open from 7:00 am to 3:00 pm. Admission is free and table space is \$3.00. Door prizes will be awarded. Talk-in on 146.34/.94. For further information, contact Scott Redfearn N5BQG, Box 105, Mount Pleasant TX 75455.

AMBOY IL
APR 26

The Rock River Amateur Radio Club will hold its 15th annual hamfest on April 26, 1981, at the Lee County 4H Center in Amboy IL, one mile east of the junction of Rtes. 52 and 30, 10 miles south of Dixon IL. There will be free coffee and donuts starting at 8:00 am. Camping space will be available at a nominal charge. Six-foot display tables are \$5.00 each and tickets are \$1.50 in advance, \$2.00 at the gate. Talk-in on .37/.97 and .52. For full details, contact Charles (Chuck) Randall W9LDU, 1414 Ann Avenue, Dixon IL 61021, or phone (815)-284-6380.

NEWTON MA
APR 26

The Middlesex Amateur Radio Club will hold its first annual indoor flea market on Sunday, April 26, 1981, at the Wayland High School Commons building, located on Rte. 126, between Rtes. 30 and 20, Wayland MA, from 10:00 am to 4:00 pm. Admission is \$1.00 at the door and ample off-street parking is available. Advance reservations for tables are \$6.00 each and at the door \$7.50 each on a first-come-first-served basis. The doors will open at 9:00 am for setups. Talk-in on 147.96/.36 and 146.52. For table reservations, contact Irving Geiler WA1CDW, Apt. 8422A, 1450 Worcester Road, Framingham MA 01701.

JACKSON MS
APR 26-27

The Jackson Amateur Radio Club will host the ARRL Mississippi State Convention from 12:00 noon to 5:00 pm on April 26, 1981, and from 8:00 am to 2:00 pm on April 27, 1981, at the Raymond Road National Guard Armory, off Interstate 20, Jackson MS. Activities will include dealers, forums, a flea market, prizes, and YL prizes. Admission is free. Swap tables will be \$5.00 each day. Talk-in on 146.16/.76, 146.52, and 3987.5. Food will be available at the site on both days. A banquet will be held Saturday night at the Holiday Inn-Southwest. Please make reservations for both the swap tables and the banquet in advance. For more information, contact Nita Stone N5AGV, Rte. 1, Box 157, Brandon MS 39042, (601)-825-2060.

WOODBRIDGE NJ
MAY 2

The DeVry Technical Institute Amateur Radio Club (WA2MDT) will hold its fifth annual amateur radio and computer flea market on May 2, 1981, at DeVry Technical institute, 479 Green Street, Woodbridge NJ. The flea market will begin at 9:00 am and for those who wish to set up tables, a fee of \$3.00 will be charged. Talk-in on 146.520 beginning at 8:00 am. For further information, call Frank Koempel WB2JKU at 634-3460 or Steve Hajducek KA2IFX at 727-5962.

MEADVILLE PA
MAY 2

The seventh annual Northwestern Pennsylvania Hamfest will be held on May 2, 1981, at the Crawford County Fairgrounds, Meadville PA. The gates will open at 8:00 am. Admission is \$3.00; children under 12 will be admitted free. Indoor table spaces are \$5.00 per space and outdoor car spaces are \$2.00. Bring your own tables. Refreshments will be available. Commercial displays are welcome. Talk-in on .04/.64, .81/.21, and .63/.03. For information, write CARS, PO Box 653, Meadville PA 16335, Attention: Hamfest Committee.

GRAY TN
MAY 2-3

The Bristol Amateur Radio Club, the Johnson City Amateur Radio Association, and the Kingsport Amateur Radio Club will hold their first annual Tri-Cities Hamfest on May 2-3, 1981, at the Appalachian Fairgrounds, north of Johnson City (off Highway 137), Gray TN, from 9:00 am to 5:00 pm on Saturday and from 8:00 am to 4:00 pm on Sunday. The dealer space charge at the door is \$30.00 for the weekend for a 10 × 12 space. The advance reservation charge is \$25.00 and must be received by April 1, 1981. The dealer charge also includes security and admission for five employees. There are approximately 40 RV spaces with complete hookups renting for \$5.00 per night inside the fairgrounds. Motels are available nearby. Dealers can set up anytime after Friday noon or after 6:00 am Saturday and Sunday. Advance reservations or further information can be obtained by writing Mary S. Biggs KA4EXP, Secretary-Treasurer, Tri-Cities Hamfest, PO Box 3682 CRS, Johnson City TN 37601, or phoning either (615)-928-1818 or (615)-282-1711-x380.

GREENVILLE SC
MAY 2-3

The Blue Ridge Amateur Radio Society will hold its annual hamfest on May 2-3, 1981, at the American Legion Fairgrounds, Highway 25 bypass, Greenville SC. On Saturday, FCC exams will be given at Greenville Tech from 10:00 am till 3:00 pm. Other features will include dealer exhibits, inside flea markets, chicken/pork plates, prizes, overnight RV parking, and motel rooms available at the Ramada Inn (1-800-228-2000).

PENNS PARK PA
MAY 3

The Warminster Amateur Radio Club will hold the 7th annual Ham-Mart on Sunday, May 3, 1981, from 9:00 am to 4:00 pm (rain or shine) at a new location, Middleton Grange Fairgrounds, just minutes from I-95 or the Pennsylvania Turnpike on Penns Park Road, Penns Park PA. Featured will be door prizes, plus a grand prize to be drawn at 3:00 pm, a flea market, a free FM Clinic, and an auction. There will be refreshments, rest rooms, and shelter available. Registration is \$3.00 per person, which includes one ticket for door prizes. YLs, XYLs, and children under 14 will be admitted free. Seller (tailgater) spaces are \$2.00 (with tables available). Talk-in on 146.52 or WARC 147.69/.09. For additional information, write WARC, PO Box 113, Warminster PA 18974, or call Mark Hinkel WA3QVU at (215)-657-7295.

HAM HELP

I'm looking for any information about a typewriter, a Singer Flexowriter type 2309, manufactured by the Business Machines Division in the mid 60s. The typewriter has tape punch and tabulate options.

I need especially information on how to interface the typewriter to a Z-80-based microprocessor system, electrical and logical diagrams of the typewriter, or the postal address of the Singer Company. I'm ready to bear the expenses for copies and for mailing. Thank you very much for any help.

Dominikus Maisl DF6TQ
Wehrstrasse 37
7320 Goeppingen
Federal Republic of Germany

I am in need of a schematic diagram and operating manual for an Eico model 425 oscilloscope, produced in the 1950s. I'll be glad to pay copying costs. Thank you.

CONTESTS

from page 14

only once for each team. When DX/WK partners contact each other it counts as a double multiplier. Final score is the sum of QSO points times the total multiplier.

AWARDS:

Extraordinary certificates will be issued to the highest individual score, DX/WK teams, YL/OM teams, and score for highest single operator category. Regular certificates to the highest state, country, and Canadian province winners.

ENTRIES:

Logs must show date/time (GMT), RS, SSBer number, partner's call, mode of operation, a band, and period of rest time. Summary sheets show number of states, Canadian provinces, countries, YL/OM teams, DX/WK teams, and partner contacts. All entries must be postmarked by May 15th.

Any member desiring to enter the DX/WK team category should immediately send request to: Lyle F. Shaw KC4LF, 6329 Fairway Blvd., Apollo Beach FL 33570. For record purposes, requests should be made in writing. In the week preceding the QSO party, members wishing a partner may request one through system controls on SSBers daily systems. No team assignments will be made after the party begins.

YL/OM teams are self-evident in their operation and need not file. Single-operator category members are eligible unless entered with teams. Non-members enter single op *only!* DX/WK teams consists of a DX and WK member. The team score is the sum of both partners. Score to be determined when both logs are received. When only one log is received, credit will be given as a single operator. YL/OM teams consist of one YL member and one OM member who are related: husband/wife, father/daughter, mother/son, brother/sister. Operation must be from the same QTH, using the rig with his/her own call.

HELVETIA CONTEST
1500 GMT April 25 to 1500 GMT April 26

Use all bands, 1.8 to 28 MHz, on CW or phone. Each station can be worked once per band regardless of mode.

EXCHANGE:

RS(T) plus three-figure serial number starting at 001. Swiss stations will also give their canton.

SCORING:

Each contact with an HB station counts 3 points. The multiplier is the sum of Swiss cantons worked on each band, 26 maximum per band. Final score is sum of QSO points multiplied by the sum of cantons worked on each band.

ENTRIES AND AWARDS:

Certificates will be given to the highest scorer in each country. USA and Canadian call areas are considered as separate countries. Logs must be postmarked not later than 30 days after the contest and sent to: TM USKA K. Bindschedler HB9MX, Strahleggweg 28, 8400 Winterthur, Switzerland.

Canton abbreviations are: ZH, BE, LU, UR, SZ, OW, NW, GL, ZG, FR, SO, BS, BL, SH, AR, AI, SG, GR, AG, TG, TI, VD, VS, NE, GE, and JU.

H26 Award—for contacts made after January 1, 1979: Send a list and QSL for each of the 26 cantons worked on CW and/or phone, RTTY, and SSTV to: Walter Blattner, Postbox 450, Locarno 6601 Switzerland.

HAM HELP

Three years ago, you published a letter from us asking for hospitality on our visit to California. Thanks to you, we made many new friends and had a marvelous time.

We plan another visit to the U.S. this August and want to spend a few days in Washington DC, where we don't know anyone. If any family can offer hospitality for 3 to 4 days, we would be glad to reciprocate and offer our home for a visit.

We are an easygoing, adaptable couple in our mid-thirties who enjoy meeting people and dislike formal hotels. Michael is an electronics engineer, a ham, and a pilot. I am a children's nurse.

We live in a beautiful and historic part of England, about 2 hours from Edinburgh and the Lakes District, and about 3 hours by train from London. We love visitors and meeting people, so I am sure this vacation will be as great as our last.

Pat and Michael Stott
"Wellview"
12 Castle View, Ovingham
England NE42 6AT

I heard from a friend that there was a Dungeons and Dragons net on 20 or 40 meters and I would appreciate any info on this. Thanks.

FUN!

from page 34

6) Soviet jamming stations, intent on keeping "undesirable" broadcasts from being received in their country, legally identify themselves on CW.
7) Radio Berlin International operates from West Berlin.
8) The Voice of America is prohibited by Congress from broadcasting in any language but English.
9) There is a shortwave broadcast band allocated at 11 meters.
10) Radio Peace and Progress is a Soviet shortwave station.
11) "Suomen Yleisradio" broadcasts from Samoa.
12) SINPO is an acronym for the Special InterNational Programming Organization.
13) "The Graveyard" is the SWL's nickname for 40-meters.
14) In many countries, you have to be an SWL before you can become a ham.
15) The *International Frequency List* is a publication listing in five volumes *all* of the world's radio stations.
16) The "Worldwide TV-FM DX Association" is an organization specializing in VHF-UHF SWLing.
17) Some countries require SWLs to license their receivers.
18) WCC in Chatham MA, broadcasts news reports, in CW, on 6.376 MHz.
19) Many ship stations have the same type of four-letter callsigns as broadcast stations, e.g., KXXX.
The U.S. AM broadcast band has only 23 channels.

ELEMENT 5—HAM ACROSTIC

Guess the words defined and write them over the numbered dashes. Next, place each letter in the correct square in the puzzle. The black squares show word endings. The completed puzzle will form a statement relating to shortwave listening. (Illustration 2)

A) Medium-wave antenna....... 28 50 42 51

B) "The East is Red"........... 65 9 41 2 67

C) A shortwave station's "tongue".................. 5 13 36 8 48 16 17 46

D) Jammers produce this....... 59 18 4 15 31

E) Old-style receiver component. 62 58 60 12

F) Effect of Radio Moscow report about Soviet farming on listeners.................... 19 27 32 64

G) Element missing from Radio Moscow's news programs.... 10 14 1 33 63

H) Famous army radio station... 53 35 49

I) Woodpecker's alleged purpose..................... 55 24 25 39 38

J) SWLs throw this when a rare station is QRMed........... 43 66 3

K) Engineering society......... 29 54 6 45

L) What Germans call East Germany..................... 37 40 57

M) Spanish "I"................ 61 20

N) Iraq amateur prefix.......... 11 26

O) Number of megahertz in SWL 90-meter band.............. 21 22 23 56 47

P) RTTY press station's test letters...................... 44 34

Q) Your author's former call suffix 7 30 52

Illustration 1A.

Element 4:
1) True—In a series of experimental transmissions during November, 1980. More SSTV broadcasts may take place this year.
2) True—Aren't they thoughtful!
3) False—WYFR and KGEI, among others, are privately owned.
4) False—They're commercial stations transmitting business or safety traffic.
5) True—Radio energy from the giant planet can be detected at those frequencies with the proper receiving gear.
6) True—Ironic, isn't it?
7) False—East Berlin.
8) False—Like most international broadcasters, the VOA transmits in dozens of languages.
9) True—25.600-26.100 MHz. Just below you-know-what.
10) True—Peacefully progressing toward what?
11) False—It's Finnish for Radio Finland.
12) False—It's a reception report form, similar to the amateur RST system. The letters stand for: Signal, Interference, Noise, Propagation, and Overall merit.
13) False—It's the term applied to the upper end of the U.S. AM broadcast band where many low-powered stations are grouped.
14) True—This is especially true in many eastern European countries where SWLs must obtain a certain number of amateur QSLs before they're allowed to transmit. So answer those SWL QSLs!
15) False—Amateur, maritime, experimental, and a few other types of stations aren't listed, but just about everyone else is. The ITU publishes it.
16) True—You can write them at PO Box 97, Calumet City IL 60409.
17) True—As a matter of fact, most countries slap a fee on radios and TVs—a way of raising revenues to subsidize government broadcasting.
18) True—Great code practice.
19) True—Confusing, isn't it?
20) False—One hundred and seven channels, but more are on the way as soon as the FCC can add more by pushing existing stations closer together.

Illustration 2A.

SCORING

Element 1:
Twenty points for the completed puzzle, or 1/2 point for each question correctly answered.
Element 2:
One point for each station you matched to its QTH.
Element 3:
One point for each word unscrambled.
Element 4:
One point for each correct answer.
Element 5:
One point for each correct definition. Give yourself 10 extra points if you deciphered the message.

Rate your SWL skills as follows:

1-20 —You listen to shortwave on a radio purchased from a sidewalk vendor. Can sometimes hear Radio Moscow.
21-40 —You write weekly letters to "DX Mailbag" and are deeply thrilled when you hear your name announced on the air.
41-60 —You monitor Radio Warsaw while working Novices on 40.
61-80 —You log countries by the dozen and are the object of extreme envy from your peers.
80-100 + —A real pro. You're probably interviewed by Dan Rather for your interpretation of foreign broadcasts during world crises.

Next month: ARRL

HAM HELP

I am trying to locate Icom 22As, 215s, or similar radios—in working condition—that can operate just above and just below 2 meters (for MARS and similar applications).

Jim McCallum WB6INJ
10051 Perdido St.
Anaheim CA 92804

I need some help learning to speak Nynorsk, the "other language" spoken in Norway. I have some books and can get along fairly well in Riksmaal, and now it's time to learn Nynorsk.

Perhaps there are amateurs living in the USA who speak this language or one of its dialects. I would like to arrange a weekly sked on 75 or 40 SSB to help get this pronunciation straight—not to mention the grammar. Drop me a line and we'll work up a sked.

Tusin takk og paa gjensyn!

Nils R. Bull Young WB8IJN
920 Greenheart Drive
New Carlisle OH 45344

I need the manuals for and any details on converting the Heathkit HW-29A and Lafayette HE45a 6m rigs to FM. I would also like to convert a Gonset IV to FM. I will pay for all expense of copying and mailing.

Richard McCubbin
535 Church St.
Portland MI 48875

My hobby is listening to shortwave radio and DXing. I need help because I recently purchased a used Hallicrafters model SX-110 receiver, but have been unable to obtain an operator's manual. If anyone has an operator's manual, please contact me. Thank you.

Edward L. Gafford
221 Royer Court
Louisville KY 40206

I am interested in hearing from Field Day 2 owners about what kind of results the unit gives with less than perfect code, sloppy code, QSB, QRM, etc.

Berand Kirschner WB9YCQ
4439 Jupiter Drive
Riverside CA 92505

I am looking for a crystal-controlled CB rig which has 4 to 6 or more channels and separate crystals for transmit and receive, in LA or Orange counties.

Al Gordon
1726 Sprockels Lane
Redondo Beach CA 90278
(213)-372-8560

I need information and a service manual for the Heathkit® DX-100 transmitter, and would also like to know of any modifications done on the rig. I'll pay for copying. Thanks.

John S. Lee KA4EPR
17401 NW 20 Ave.
Miami FL 33055

I'm looking for information on a Northern Radio Company, Inc., F.S. diversity converter, circa 1956. It is a type 174, model 1, serial 180. I believe that this is a terminal unit for RTTY, has a variable frequency shift, and was used in the Air Force. I would really appreciate any help on this.

Gary L. Young N3ALL
Box 129
Wise's Grove Road
New Brighton PA 15066

Does anyone have any information on building test and calibration equipment for the 2-4 and 3.7-4.2-GHz ranges? Also, what would be the lowest possible cost?

Lamar Evans II
Rte. 1, Box 87C
Anacoco LA 71403

LEAKY LINES

from page 18

proper examination. Why propose quantitative growth while running the real risk of a reduction in quality?

Why should the back door be opened for unqualified persons to slip through and get amateur privileges? No one stops anybody from becoming an amateur. Why should a special route be opened for those who are unwilling to exert enough effort to earn the privilege?

And although the ARRL appears to be viewing the matter from the position that it will act in accordance with the wishes of the membership, it is very clear that in raising uncertainty about it at all, instead of opposing it from the outset, it is placing ham radio in possible jeopardy. By expressing unqualified opposition at once, the League would have served notice that it believes the Commission grievously wrong. And it is about time that someone stood up to the FCC for a change. Many FCC proposals in recent years have shown rather clearly that the Commission is not overly impressed with the necessity of safeguarding the continued existence of amateur radio, at least not as we have known it.

I believe that the digital licensing proposal is one of the most dangerous ever made, and I exhort all amateurs to ponder well what it can mean in terms of the survival of our hobby. It must be resoundingly opposed, and ARRL directors must be made aware that their constituents are solidly against it. Our League must take a position consistent with the wishes of its membership, for if it fails to do this, it no longer deserves to be considered the leading representative body in ham radio.

AWARDS

from page 44

tor Service, and radio communications throughout Australia in general. Today, thanks largely to the efforts of John Flynn, every cattle station and settlement in the Australian outback has radio communications.

Flynn spent his whole working life in the outback helping others, no matter what nationality or color. Last year was the 100th year since the birth of John Flynn, and the Alice Springs Community College Radio Club had 2,000 certificates printed in memory of this great man.

Amateur operators worldwide are encouraged to participate in recognizing the achievements of such a radio pioneer.

To qualify, all VK stations must make three contacts with Alice Springs club members; all other stations of the world must log at least two contacts with Alice Springs club members. The award is also available to SWL stations who can log at least 3 station contacts heard. There are no band or mode restrictions for the award. Listen for VK8s.

To apply, have your contacts with the VK8s of the Alice Springs club verified by at least two radio amateurs or a local club secretary. Keep in mind that the same station may be worked more than once if the contacts are separated by 24 hours.

Enclose your application along with a donation of $3.00 to the Awards Manager. All funds generated by this award will be given to charity. Send your application to: ASCCRC Awards Manager, PO Box 2953, Alice Springs, Northern Territory, Australia 5750.

VK8 OUTBACK AUSTRALIAN AWARD

My thanks goes to Laurie Day VK8LD for forwarding the latest details about the very popular VK8 Outback Australian Award.

To qualify for the award, applicants must make contacts with members of the Alice Springs Community College Radio Club. VK stations and SWLs must contact at least 6 club members; all others must make a minimum of 3 club member contacts. To be valid, all contacts must have been made after December 1, 1979. There are no band or mode restrictions.

A list of club members can be obtained by sending your request with 3 IRCs or $1.00. Fees for the award are: $2.00 for VKs; $2.50 for DX stations. Forward your list of contacts, verified by two fellow amateurs, to The Awards Manager, VK8 Outback Australian Award, PO Box 2953, Alice Springs, Northern Territory, Australia 5750.

HAMVENTION STATION

WD8EOL and W8ILC have informed us that special-event station W8BI will be operating from the Dayton Amateur Radio Association's communications van on Hamvention days, April 24, 25, and 26, 1981. Special Dayton Hamvention certificates will be sent to anyone contacting W8BI who sends a large stamped envelope. Send QSL to W8BI (special event station), P.O. Box 44, Dayton OH 45401. Frequencies: 14.295, 7.230, and 7.125 (CW). Times: Friday, April 24, 1800—2200 UTC; Saturday, April 25, 1400—2200 UTC; and Sunday, April 26, 1400—1800 UTC.

W2NSD/1 NEVER SAY DIE

editorial by Wayne Green

from page 8

Like anything else, if you are going to make money at gambling you should know more than the information you get in *Reader's Digest*. The fact is that there are a number of very good books on the subject of gambling... and on how to win. The further fact is that if you know how to gamble and have some experience, you can win consistently. I'm not just talking about counting the cards at 21, which is old hat by now... I'm talking about craps.

Not having done my homework... and not really having much time... I avoided the gambling this trip.

CES has nothing whatever for the ham business. It is mostly involved with things like hi-fi, car stereo, calculators, digital watches, radar detectors, television sets, VTRs, and dirty-movie video cassettes. They had one whole room devoted to porno cassettes!

There were a few microcomputer exhibits... such as the new H-P personal computer system, the new color Commodore system, T.I., Atari, Mattel, Bally, NEC, Casio, Panasonic, Quasar, APF... etc. Apple wasn't there, but I did run into Steve Jobs, who recently became a multimillionaire when the Apple stock went on the market. Every

DXPEDITION CALENDAR

To better serve our readers we are considering beginning a DXpedition Calendar. If you are interested in having your operation included in this listing, please include locations, dates, callsigns, frequencies, operating hours, QSL info, etc., along with the name of a person to contact if there are any questions about the operation.

Please send your DXpedition info to Editorial Offices, *73 Magazine*, Pine Street, Peterborough NH 03458, attention: DX Calendar.

NET OPERATIONS

We would like to accumulate a list of active nets and their purposes for a possible directory. If you are interested in having your net operation listed, type or print (neatly) its particulars (purpose, dates, frequencies, etc.) along with the name of someone to contact should there be any questions. Depending on the response, a very comprehensive special-interest directory could result.

If you would like to participate, write to Editorial Offices, *73 Magazine*, Pine Street, Peterborough NH 03458, attention: Net Operations.

HAM LICENSE CLASSES

If you or your club are giving or planning to give code and theory classes, please let us know. Include dates of each session, license classes taught, and the name of someone to contact for complete information. With this, we can perhaps direct an aspiring amateur to a nearby class. More than one ham has been asked about helping a beginner or a ham who wishes to upgrade and was unaware that the club across town was having classes.

If you would like to have your classes listed, please write to Editorial Offices, *73 Magazine*, Pine Street, Peterborough NH 03458, attention: License Classes.

time the Apple stock drops one point he loses about $5 million...how'd you like to be in that position?

A lot of the consumer electronics magazines were there. I got to see a recent issue of *S-9* ...now shrunk to 72 pages, with just 12 pages of advertising ...even thinner than *onComputing*, with its 15 pages of ads. *CB Magazine* is really looking good, with its increased ham orientation...thus encouraging CBers to move on into hamming. Gordon West, the *CB* editor, has rebounded well after his experience with the ARRL. Apparently the shafting was discussed at length at SAROC.

WEST QUESTIONS

Since a lot of amateurs get all bent out of shape at any mention of the League, let's steer clear of that organization entirely. Besides, I'm really sick of hearing the old saw that I am anti-League. I'm anti the bad guys, no matter where they are ...in Washington, Newington, or Oregon.

Now, to cases. Gordon West, the editor of *CB Magazine*, recently ran for office in a national club and was refused the right at the last moment to have his votes counted by that club's general manager. Attempts at getting a rational explanation of this weird and seemingly dictatorial move have so far been frustrated. Please then consider this a general call: If anyone in the readership of this magazine knows the real reason for this move, please write it up so it can be published. Please send this information to all ham magazines and let's see which have the guts to print the facts.

HAM HELP

I am in need of a service manual on military transmitter T368D/URT. I will copy and return or possibly purchase outright. Thank you.

A. K. Seput KA2AYS
258 Hillside Avenue
Palisades Park NJ 07650

paddles and it's ready to go with automatic and programmable memories. It has iambic operation and dot-dash memory.

Five-level Baudot is transmitted at 60 wpm. RTTY and CW ID are provided via the ID button and message A. Carriage return, line feed, and letters are sent automatically on the first space after 63 characters on a line. All up and down shift is done automatically. A down shift occurs on every space to quickly clear any garbles in reception. The Baudot mode also includes all applicable features of the CW mode.

In the ASCII mode, transmission speed is 110 baud. Both upper and lower case are generated, and all the features of the Baudot mode are included here also.

Controls and keys on the 494 are positioned logically and labelled clearly; pots are used for speed, volume, tone, and weight because they are easier to use than keystroke sequences and they remember your settings even if power is lost or turned off.

The MFJ-494 operates on 9-12 V dc or 110 V ac with optional ac adapter. The same keying circuit used in all MFJ keyers is used in the MFJ-494.

Available options for the keyboard include the MFJ-53 and the MFJ-54. The 53 is an AFSK plug-in module. The output of the module plugs into the mic or phone patch jack for FSK with SSB rigs and AFSK with FM or AM rigs.

The MFJ-54 loop-keying, plug-in module is a 300-V, 60-mA, loop-keying circuit that will drive your RTTY printer.

Desco Industries' precision tweezer.

ELECTRICAL POLLUTION CONTROL

Electrical pollution drives microprocessors bananas! Power line electrical noise, hash, and spikes often cause erratic operation. In addition, severe spikes from lightning or heavy machinery may damage expensive hardware.

Electronic Specialists recently announced the Super Isolator, designed to control electrical pollution. Incorporating heavy-duty spike/surge suppression, the Super Isolator features 3 individually dual-pi-filtered ac sockets. Equipment interactions are eliminated and disruptive/damaging power-line pollution is controlled. The Super Isolator will control pollution for an 1875-Watt load. Each socket can handle a 1000-Watt load.

For more information, contact *Electronic Specialists, Inc., 171 South Main Street, Natick MA 01760; (617)-655-1532.* Reader Service number 486.

PRECISION TWEEZER HAS BUILT-IN LIGHT

Desco Industries has added three models of battery-powered lighted tweezers to its line of electronic assembly aids. These tweezers all have stainless steel blades and are powered by a single AAA battery.

A low-cost, plastic-case model is available for working in poorly-lighted field situations. Two stainless-steel-case models are available, one with a straight tip and one with an angle tip.

For more information, contact *Desco Industries, Inc., 351 F Oak Place, Brea CA 92621; (714)-990-3005.* Reader Service number 482.

YAESU FT-902DM

Yaesu has announced an improved version of the FT-901DM, the FT-902DM. While the 902 retains most of the features of its predecessor, several important changes have been made.

The 902 covers all present and proposed HF amateur bands, including the new WARC bands. The digital frequency readout has been improved to eliminate the need for recalibration when changing modes or bands. The built-in keyer features both dot and dash memories, and the receiver's dynamic range has been improved. Last, but not least, the vfo knob now tunes in the right direction!

For more information, contact *Yaesu Electronics Corp., 6851 Walthall Way, Paramount CA 90723.* Reader Service number 485.

TEMPO S-4

Tempo, a pioneering manufacturer in the field of synthesized hand-held radios, has announced a new 440-MHz FM hand-held. The new S-4 is nearly identical to the other Tempo hand-helds which are offered for the 2-meter and 220-MHz bands.

Available accessories include 12- or 16-button touchtone™ pads, CTCSS tone encoder, and a leather carrying case.

For more information, contact *Henry Radio, 2050 S. Bundy Dr., Los Angeles CA 90025.* Reader Service number 481.

NEW MFJ HF WATTMETER

The new MFJ-814 HF wattmeter/swr meter has a frequency range of 1.8-30 MHz. It reads forward and reflected power on two scales (2 kW and 200 Watts) on a 2-1/2" wide × 1-1/2" high lighted meter (light

The MFJ-814 HF swr wattmeter.

requires 12 volts).

This power meter also reads swr directly and is calibrated up to 6 to 1 swr. Three push-button switches let you switch between power and swr, high and low power, and forward and reflected power.

Eggshell white with black top and sides, the meter measures 6-1/4" × 3-1/2" × 3-1/2".

For more information, contact *MFJ Enterprises, Inc., PO Box 494, Mississippi State MS 39762; (601)-323-5869.* Reader Service number 484.

NEW MODEL FROM ALUMA TOWER

Designed especially with the ham operator in mind, Aluma Tower's new extra-heavy-duty aluminum tower meets our special needs. All uprights and cross braces are 1" seamless drawn-aluminum tubing with stainless steel aircraft cable connecting the telescoping sections. The mast is 2" diameter × 8' long and is supplied bolted in place.

Aluma Tower's telescoping construction and tilt-up style enable it to withstand any weather conditions.

For more information, contact *Aluma Tower Company, 1639 Old Dixie Highway, Vero Beach FL 32960.* Reader Service number 479.

HY-GAIN ADDS THREE NEW PRODUCTS TO TOWER LINE

Telex Communications, Inc., has announced the addition of three new products to its Telex/Hy-Gain tower line. The HG-70HD, a new 70-foot (21.3 m), self-supporting crank-up tower, is the tallest of seven towers now offered by Telex/Hy-Gain. The tower is all steel, has four sections, and features an improved guide system providing rigid, close-tolerance structural support while leaving the tube ends open for complete surface galvanizing and unrestricted moisture drainage. This heavy-duty tower was designed for antenna loads of up to 16 square feet (1.5 sq. m) in winds of up to 60 mph (96.6 kmph). The top section is pre-drilled for thrust bearing bolts, and a rotor mounting plate is included.

Hy-Gain has also developed a new electric winch system, model HG-EW, that fits the new HG-70HD as well as the existing 54-foot (16.5 m) HG-54HD and the 52-foot (15.8 m) HG-52SS. The winch control box can be locked, which allows the tower to be secure in either the extended or retracted position. It has a limit switch which prevents a possible overload at the upper stop position. A manual crank is supplied also in the event of an electrical power failure. The HG-EW is equipped with an automatic brake which is always in positive engagement when the winch is not operating.

This winch system can be converted at any time to remote-control operation by adding the new Hy-Gain tower control (HG-EWRC) which has been specifically designed as a modular addition to the HG-EW winch. This remote-control unit allows the operator to raise and lower the tower from a remote location such as a ham shack. The control displays upper and lower limit positions, up or down operating direction, and also provides a fail-safe sensor and indicator which automatically shuts off the winch should extreme side loads affect tower telescoping. Both the winch and the remote control are available for 110- and 220-volt operation.

For more information, contact *Hy-Gain, 9600 Aldrich Ave. South, Minneapolis MN 55420; (612)-884-4051.* Reader Service number 483.

LETTERS

from page 24

Peking, and the street next to it was full of shops. One large department store had a department selling only radio parts such as resistors, capacitors, tubes, transistors, etc., for people who wanted to repair their own radios.

They also had a black and white TV on sale for about $1000 US.

I saw two fairly large telegraph keys but I could not find anyone who spoke English to find out what they were used for.

There was also a shop nearby which sold only TVs. Incidentally, mine in the hotel did not work.

Fred Barnes WA8PCT
Parma OH

ITS UGLY HEAD

It was interesting to read the letter in the July *73* sent to Dr. Zbigniew Brzezinski by Dave Clark K8MPF regarding his proposal to boycott stations in the USSR using the special Olympic prefixes. In the letter, Dave states, "Normal communications with the Soviet U prefixes should be encouraged since amateur radio does provide a system of direct communication to all parts of the world regardless of political relations."

I should like to point out to your readers that in the case of the Soviet Union this is not entirely true. Since June, 1967, the Soviet authorities have forbidden their hams to communicate with Israeli amateur stations using the 4X or 4Z prefix. Although to my knowledge there has never been an official press release to this effect on the part of the USSR, it is common knowledge here, and a call to a U or an R station or what have you is almost always ignored except for the occasional station who will say "sorry, can't work you," or "no contact." For the Israeli DXer or contest fanatic, this is a serious handicap as this makes it virtually impossible to contact or confirm 19 Soviet Republics (countries) and four zones.

What is interesting is that in the last few years, amateurs visiting Israel from other countries and operating here with their own calls with a slant 4X tacked on the end find themselves besieged in pileups of Russian amateurs calling them. This indicates that the Russians have relaxed their boycott of amateur radio in Israel to the extent of allowing contacts *only with non-Israelis operating here*. The reason for this is not clear, but it could likely be to avoid bad public relations with American and European hams visiting here.

After much deliberation on the problem, the Israel Amateur Radio Club has asked amateurs operating here with foreign callsigns to avoid contacting Soviet stations until the Soviet Union rescinds its ban on contacts with Israeli stations, and to make this clear to the Soviet stations calling them.

It sure is a pity that politics raises its ugly head in this area. It should be added, however, that we have no problems contacting the other eastern European countries, but the USSR countries are all missing in the tallies of hams here who have been DXing since 1967. We are still hopeful that one day this condition will be reversed.

Hams visiting Israel are invited to use our 2-meter repeaters and meet the boys (and girls, hi) here. We use the European band plan here, and the repeaters are as follows: HAIFA—R0—145.000 in, 145.600 out (1800 Hz tone access); SAFED (upper Galilee)—R3—145.075 in, 145.675 out; BEERSHEBA—R5—145.125 in, 145.725 out; TEL AVIV—R7—145.175 in, 145.775 out, and JERUSALEM—R9—145.225 in, 145.825 out. Only the Haifa machine requires a tone burst; all the rest are straight carrier access.

VHF CONTESTING

A short note to express my interest in the January article, "VHF Contesting." The appetizer was delicious; now when do you begin the meal? You provided a few details on equipment, antennas, spacings, and just enough to evoke, "yes, yes, go on." So. . . let's have more of the detail so that more of us can learn more and successfully give it a go.

Bob Munsey K6PIU
Canoga Park CA

WORK THE WOODPECKER

The January issue of *73* has a couple of items on which I would like to comment.

First is the Woodpecker. When it first came on the air, the DX fraternity on 15 and 20 had a lot of ideas of what might be done to chase it off the ham bands. The "H5H" sequence was one of them, but not very practical for those of us who

don't have keys as part of our ham station or who are essentially lazy. We don't have the power to compete with Radio Moscow to QRM them, but radar depends on receiving an echo for its results and that echo can't possibly be a match for a ham kW beamed in the right direction with a similar signal. All one has to do is tape record a few minutes of the woodpecker and play it back at them!

If all the "tuner uppers" and "pileup" participants would get together on a "Woodpecker's Sunday" and send out the taped signal all over the band at the same time, perhaps they might get the message.

The other is your story, "Over the Hump" and the references to AC4YN. Of course, before the war AC4YN was the legendary contact that you had to work to get Zone 23. Your article mentions Reggie Fox as AC4YN, but I have reason to believe that it was a British Army group operations and that there were others that used the call either before or after Reggie.

I served in Italy during WWII at AFHQ Italy in a combined US Signal Corps/Royal Signals operation, which has made me eligible for membership in the Royal Signals Amateur Radio Society. Currently, there are about ten U.S. hams who belong to RSARS. I got a life membership back when the pound was worth $1.80. I get a lot of mileage out of that connection with QSOs with "G" stations. At the time I joined, one of the officers was Sir Evan Neppan G5YN. There was quite a story on Sir Evan in the Society publication, *Mercury*. He was a career officer in the British Army, had operated from exotic spots all over the world, and had been knighted by the Queen. It appears that one of the calls he had held was AC4YN, so you figure that out! I had a nice letter from him when I joined and have worked him on the air.

Col. Edson B. Snow, AUS Ret.
Pompano Beach FL

REVIEW

from page 30

ed a measure of additional gain.

Our basic downconverters soon acquired an elaborate "look" which reminded us of a mini-TVRO setup, and we somehow felt we had set new DX records for solid MDS reception in this heavily wooded and mountainous area of the United States. One aspect has definitely proven true: Signal paths which are not line of sight are difficult to predict and use. Raising antenna height to acquire line of sight is often the only logical alternative.

Some additional members of our group decided to construct competitive and more expensive downconverters, reasoning that complexity and cost should provide better results. Unfortunately, we did not find that true and had to work like heck to get marginally acceptable results from those units. Our previously acquired knowledge of microwave construction techniques was also required to supplant marginal instructions used with these units.

Fortunately, however, we all came out winners at the end and except for me, everyone is presently enjoying watching special TV programs. My particular converter works great, but I'm 20 miles, two mountains, and one dense forest from the MDS transmitter. Plans include wrestling a 3.5-foot parabolic dish/downconverter setup to the top of an 80-foot pine tree and adding a second TV tuner between the converter and the television for additional gain. We're not giving up yet!

In conclusion, the Universal Communications downconverter kits have proven their worth and are very reliable units. If you would like to get your feet wet in microwave, MDS, or weather satellite reception, these units are a good starting point. At the present time, I'm also considering the feasibility of modifying a unit for TV satellite reception. A number of additional items also will be required, but a working system for under $400 looks very promising.

The original downconverter board described here is available from *Universal Communications, Box 6302, Arlington TX 76011.*

Realistic DX-200 communication receiver.

DX-200 RECEIVER

The DX-200, sold by Radio Shack, is a general-coverage receiver. It tunes five bands: 150 kHz to 400 kHz, 520 kHz to 1.6 MHz, 1.55 MHz to 4.5 MHz, 4.5 MHz to 13 MHz, and 13 MHz to 30 MHz. It is designed for the reception of the three most-used forms of amplitude-modulated signals, which are double sideband with carrier (AM, or 6A3), single sideband without carrier (SSB, or 3A3j), and make-and-break radiotelegraphy (CW, or 0.1A1). The basic design is the classic single-conversion superheterodyne with an intermediate frequency (i-f) of 455 kHz. The circuit provides one stage of preselection before the frequency conversion.

To evaluate this receiver, it was compared with two others, each of recognized performance capability but of other design and in a higher cost bracket. A coaxial switch was used to switch the reference antenna among the three receivers, thereby ensuring a comparable signal to each. In addition to off-the-air signals, a URM-25D signal generator was used to make measurements of sensitivity and of image rejection.

One of the comparison receivers was a Yaesu Model FRG-7, which uses the Wadley Loop system. This involves triple conversion, with a first i-f of 55 MHz, to ensure almost total freedom from images. The other was the receiver section of a Kenwood TS-120S. This is a single-conversion receiver with an i-f of 8.8 MHz. Unless otherwise stated, off-the-air signals were obtained from an 80-meter trapped dipole antenna mounted 50 feet above ground.

Initially, the DX-200 was tuned to the AM broadcast band. Here it performed very well indeed. Both selectivity and sensitivity were excellent, and the stability adequate. I rated it on a par with the FRG-7 with but one exception. With the rf gain control turned fully on, the set broke into oscillation, causing severe distortion. Backing off slightly on the gain control stopped the distortion. With a short indoor antenna, the rf gain could be advanced fully without distortion.

The second check was on the longwave band. The DX-200 did quite well. It is one of the very few longwave receivers I've heard that doesn't bring in local broadcast band stations almost as loudly as LF stations! There was some slight spillover but not enough to be troublesome.

In the high-frequency range, the receiver displayed varying degrees of performance. For the reception of shortwave BC stations, it did quite well over the whole spectrum, fully equaling the FRG-7 in all respects save one: Image rejection above 5 or 6 MHz is very poor. The selectivity and sensitivity were fully adequate for SWLing and I didn't notice any frequency drift. Even the sponginess of the bandspread dial was not too objectionable.

For the reception of HF SSB stations, the level of performance dropped. In the MF 160-meter band and in the HF 80- and 40-meter bands, signals could be demodulated with ac-

ceptable intelligibility. As I went higher, the signal quality became much worse. On 11 and 10 meters the clarity approached zero! It appears that there is enough instability in either the HF oscillator or the beat frequency oscillator (I suspect the former) to introduce severe fuzziness. These signals were, of course, also checked on both the FRG-7 and the TS-120S to make sure that the difficulty originated in the DX-200 and not in the transmitter or in some propagation abnormality.

CW reception is a bit better than that of SSB in that one can read a T5 note with no difficulty. In fact, there are operators who prefer modulated notes over that of a pure sine wave! The sponginess of the bandspread dial makes tuning in a CW signal a bit of a job, but it can be done with practice and patience. It's a wee bit more tedious than the FRG-7; the TS-120S, of course, presents no tuning difficulties.

The next job tackled was attempting to improve the image rejection for frequencies above 5 or 6 MHz. Two passive preselectors (shown in Fig. 1) were tested. One is of a type designed to match a random-length endfed antenna to a low impedance input to a receiver. The other is for low-Z to low-Z; it was used with the trapped dipole.

Both preselectors performed about the same. They helped to attenuate images in the 5- to 10-MHz range, but above 10 MHz their selectivity curves were so broad that they provided insufficient attenuation to the image. And, of course, this is the region that most needs additional image attenuation! Scratch the idea of a passive device.

An active preselector, a leftover from the day when I had a DX-150 receiver, was excavated from my junk box. Its circuit is shown in Fig. 2. In addition to providing preselection, it supplies an appreciable amount of gain. Now the DX-200 had plenty of gain, but I noticed that it performed somewhat better with its rf gain control backed off a bit from fully clockwise. From that standpoint, the additional gain from the active preselector is valuable.

Its image rejection ability was evaluated with signals from the antenna and signals from the URM-25D signal generator. For the latter, a signal was injected into the receiver at a level which caused a predetermined deflection of the receiver's S-meter. Both that deflection and the URM-25D's microvoltmeter indication were noted. The DX-200 was carefully tuned to the signal's image and its S-meter reading noted. Next, the URM-25D's output was advanced until the referenced S-meter deflection was again reached. Reading the new value from the microvoltmeter provided an indication of the receiver's image rejection capability. Then the active preselector was introduced into the circuit. It was tuned to the URM-25D's output frequency and the whole series was repeated. The additional increase in signal generator output to return the S-meter to its referenced value gave a comparative indication of the effectiveness of the preselector. No attempt was made to tabulate absolute values; only comparisons were desired.

The results showed that neither the FRG-7 nor the TS-120S had enough image response to be recorded. Also, the active device was significantly better than either of the two passive preselectors. Above about 16 MHz, however, even the active circuit's image rejection became marginal. It added useful gain, however.

My conclusion is that it is not feasible to attempt to make significant improvement in the image rejection capability of a receiver having an i-f of 455 kHz for reception of signals above 16 MHz unless one is prepared to use at least two and probably three additional tuned circuits.

The lack of good image rejection on the higher frequency ranges does not mean that the DX-200 is not a good receiver. It is highly sensitive and is as selective as one might want for reception of AM voice and music broadcasts. It is stable enough to require no retuning once you've centered on a station. For many decades radio listeners used receivers having the same basic circuit as the DX-200 and found such receivers quite satisfactory. The average SWL will find that the DX-200 fulfills his requirements in a satisfactory manner.

I found many things to like about the DX-200. Its bandspread is very good, the quality of the internal speaker is better than average, and there's a ¼" headphone jack on the front panel. The external speaker jack on the rear is of the miniature type. Inspection of the schematic wiring diagram reveals that there's a resistor in series with the internal speaker and also one in series with the headphone jack, but none in series with the external speaker jack. Evidently, the audio output is higher than the internal speaker can handle, yet this speaker provides room-filling volume.

The wiring diagram makes an interesting study. The receiver's designers came up with some neat tricks—too many to comment on. They have one practice I cannot admire, though. That is designing the receiver to have its power supply activated at all times when the 117-volt power plug is inserted into the wall socket.

Still on the subject of the wiring diagram, it would appear that the set's overly-optimistic S-meter might be made more nearly realistic by adjusting resistor VR202. If its 1k range is insufficient, the addition of a series resistor might do the job. If not, you always can tame an overly-active S-meter with a shunt resistor.

The DX-200 has an owner's manual that's really outstanding. In addition to information on the receiver, it has many excellent tips on using it. I did find four items in it that irked me; all related to nomenclature. The manual calls all random-length endfed antennas "long wires," which is incorrect, as a long-wire antenna is one many wavelengths long! The other three were in the list of radio terms, which showed "73s" instead of 73, "88s" instead of 88, and XYL instead of YF. But those four glitches do not seriously detract from the overall excellence of the manual.

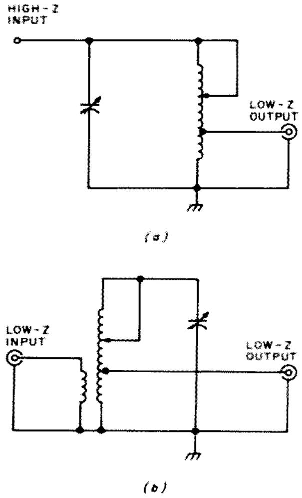

Fig. 1. Passive preselector circuits for the DX-200. (a) For random-length endfed antennas. (b) For low-impedance antennas.

To sum up, the DX-200 is as good a receiver of its design as you're likely to find for the price. Its design, the classic single-conversion with an I-f of 455 kHz, has inherent limitations. Within these limitations, the DX-200 rates highly, with just two exceptions: the lack of spectral purity in the oscillator and the rubbery feeling of the bandspread tuning dial. If these were corrected, Radio Shack would have a receiver that would be difficult to fault.

For further information, contact *Radio Shack, a division of*

THE BECKMAN 3010/TECH 310: A USER REPORT

Pssst...pssst. Yeah, you. Stop leafing through these pages for a second, I want to ask you a question.

Well...OK, but don't try to sell me anything—I get enough of that from TV.

I promise—no sales pitch today. I would like to know, of all your workbench equipment, which instrument is essential to your testing needs?

That's easy: my ohmmeter.

I agree, the multimeter is the foundation for most of our diagnostic procedures. What is the reason for its wide popularity? Why do we depend on it so much? Many test instruments have proven invaluable as troubleshooting aids, yet they enjoy little of the multimeter's success. I think that a prime factor for the analog's success is its tradition of combining versatile service with a low price tag. Today's new digital multimeters continue to carry out this fine tradition, perhaps improving upon it. One of the better of these is the Beckman Superswinger.

Hold it! Are you sure you got the name right? I've been shopping for a DMM, and I have never heard of this Superswinger.

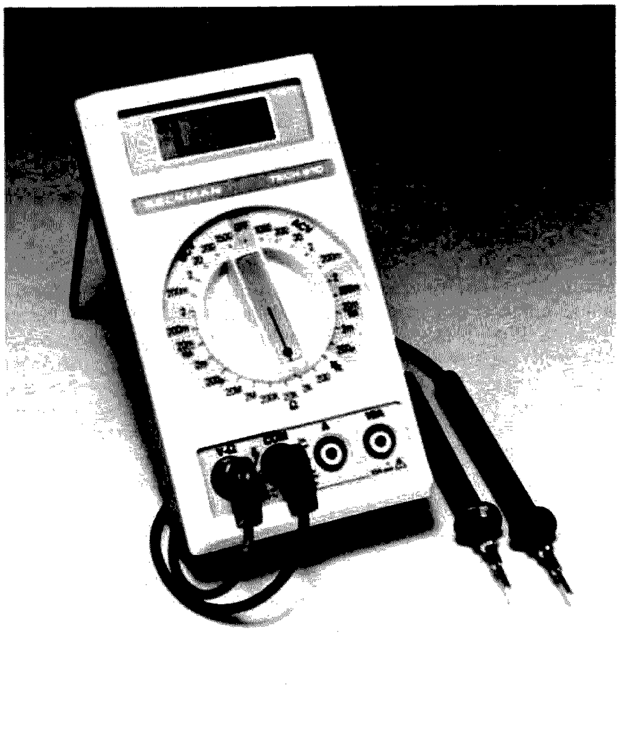
I'm positive! You see, I made up the name.

Boy, that's all I need! As if it weren't enough trouble keeping track of all the real meters, now some joker invents his own.

If you will be patient a moment, I hope to clarify the situation. I devised this designation to represent two *real* Beckman models, the Tech 310 and the 3010. A sound reason exists for merging the two: they're identical. Identical, that is, if you discount the 3010's blue case and the 310's tan-colored one. Selling the same product in different boxes is strange in itself; stranger still is asking the same price.

Strange? It sounds dumb to me. Why go to all the trouble and expense in the first place?

A very good question. The answer lies within the mystical realm known as marketing. Beckman, with logic only a marketing analyst could love, elected to attack the formidable meter market with two entirely separate sales forces. The first, with the 3000 series, focuses its efforts on the large industrial user, while the 300 team tackles the end-user market. I am told that this dual-meter, dual-designation approach is invaluable for accurately gauging market penetration. While on the subject of dual designations, unless clarification is needed, I shall confine my comments solely to the 3010.



Beckman Tech 310 digital multimeter.

One fact stands out through all of marketing's dust and confusion: Beckman makes an incredibly good meter.

Ha! I've heard that one before. Prove it.

I will substantiate my claim with some cold, hard facts: Beckman's unadulterated specifications for the 3000 series. This information applies equally to the members of the 300 group, but there is an additional meter not shown in the specs—the Tech 300. It has the 3010's specifications except that the dc voltage accuracy is reduced from 0.25% to 0.50%. In addition, both the 10-A current range and the Insta-Ohms™ function are absent.

I like the specs, but how much would it syphon from my bleak-looking bank account?

I'm glad you're pleased with the 3010's numbers. Nevertheless, as you must already know from examining today's market, most DMMs have attractive-looking figures. What earns the Beckman its $140 price tag is its superior performance in the real world.

$140! My wife would kill me.

I realize that the price tag seems a bit heavy, but the excellent quality of the 3010 with its easy, dependable, and versatile operation makes it a great buy. Take operator ease. Many users are momentarily dumbfounded when confronted by some DMMs and their rows of push-buttons or multiple switches. With the Beckman, you will never have this problem. There is positively no confusion or ambiguity in using the 3010's solitary, large, analog-styled selector switch.

I admit the 3010 looks easy to use, but why should I buy it, when I can get a cheaper DMM that is just as good?

Purchasing a less expensive digital multimeter is by no means a difficult task. Matching Beckman's craftsmanship is another story. To be fair, let's make a quick comparison of the two meters. I think you'll agree that ruggedness is a desirable attribute in test equipment, and essential for all portable instruments. Multimeters are no exception and must endure a multitude of sins in the form of knocks, bumps, and scrapes. Some of these can be nastier than others; a fall could be fatal. If you were to accidentally knock your bargain meter off the top of your workbench, would it survive?

Ouch! I hope so. Although I do remember dropping my VOM once; it never worked the same again.

I'm afraid your bargain-basement friend will share much the same fate: dead on arrival. If you owned a 3010 in this situation, you may suffer heart failure, but the meter will remain healthy. Meeting military shock and vibration standards, the 3010 is capable of withstanding the abuse from a six-foot fall without blinking a digit. This ruggedness stems in part from the fire-retardant, high-impact ABS plastic case, but, to a larger extent, it is due to Beckman's careful engineering. This attention to detail is evident when you examine the outside. All vulnerable areas, including the 3½-digit liquid-crystal display, function switch, and test jacks, are recessed out of harm's way. Venturing inside, we find the explanation for the 3010's great strength—an unbelievable low number of parts. The credit for the fewer than forty active components goes to a custom-designed CMOS LSI multiprocessor. Helped by a CD4069 hex inverter, this LSI chip performs all the active DMM functions, which results in a small, compact, and extremely reliable digital multimeter.

Ruggedness is only a start; Beckman goes much further to ensure a reliable meter with a long and healthy life. Living in the "northwets," I appreciate the extra effort that has gone into sealing the 3010. It is well-suited for this climate, offering no easy pathways for the liquid sunshine, dirt, or other contaminants. On most multimeters, the test jacks are open gateways into the interior. Beckman closes the gate by physically dead-ending these. While an O-ring protects the selector switch, a large gasket seals the LCD display area. I have been told that the 3010 is so well sealed that it will float. You need not take your DMM swimming to avail your-

self of this added protection. A recent graphic demonstration from a skeptical friend pointed this out. He watched in helpless horror as a glass of iced tea, liberally laced with sugar, dispatched his three-month-old DMM to silicon heaven.

Beckman enhances the reliability of the 3010 further by giving each meter a 100% burn-in, followed by a complete test of each function and every range. All of this results in a digital multimeter that is trouble-free and backed by a one-year warranty under which Beckman agrees that:

If the instrument fails for any reason whatsoever, except abuse, Beckman will (at its election) repair or replace the multimeter with a new or reconditioned unit of equivalent quality.

That sounds too good. Service must take forever!

Wrong. There is only one word that can describe Beckman's service: phenomenal! You will get no excuses or interminable delays when you have an ailing meter. Instead, within one working day from the receipt of the meter at a service center, a new or reconditioned unit will be *air* shipped to you.

The 3010 certainly seems well built. Yet, that price still scares me a little.

Your reservations will fade after getting to know some of the 3010's features better. The same custom CMOS chip that helps make the 3010 so tough also contributes other useful traits. The CMOS construction in conjunction with the low-power LCD display ensures a long battery life. A 9-volt alkaline battery supplies 2000 hours of *continuous* operation. Under normal operating conditions you can expect two years of service from a single battery. That's ten times longer than other hand-held 3½-digit meters provide. Couple this longevity with a low-battery warning that signals for the last 200 hours of operation and you have erased any excuse for a dead battery. This low power drain also frees the user from external power sources, adapters, and chargers which add unnecessary weight. The 3010 weighs in at a modest 16 ounces.

In the world of micro-electronics, where minute voltages and infinitesimal currents are precariously balanced, outside disturbance from low-impedance sources can be disastrous. The 3010's high input impedance of 22 megohms babies delicate circuitry with less than half the loading of the conventional DMM's 10-megohm impedance. In fact, this meter's load factor is far lower than most VOMs.

A baby around delicate equipment, the 3010 does not play nursery games when it comes to life's crueler realities—destructive overloads. The meter will tolerate transgression as high as 1500 V dc/1000 V rms on the voltage inputs, and the resistance area is protected to 300 V dc/rms. Both can ward off evil transients up to 6000 volts in size. The 2-A current range is fused against overloads, but the 10-A range is vulnerable. Making use of an internal, 0.001-Ohm resistor, this 10-A function is totally defenseless, lacking the most paltry of fuses. A glaring omission on Beckman's part? In a way, yes, because this does open the door to operator abuse. On the other hand, by being aware of the potential danger and by observing a 30-second time limit, one can extend the upper current boundary to 20 Amps. I have successfully made measurements in excess of 17 Amperes with no ill effects. However, I cannot stress strongly enough the need to strictly adhere to the 30-second limitation!

Another feature worth mentioning is the in-circuit diode/transistor test function. One aspect of the 3010 is that all the resistance ranges are low powered, and as such cannot forward-bias a semiconductor. This necessitates that a separate test function be added to the meter. As usual, Beckman goes first class by employing a dedicated constant-current source, which, when in operation, shows the actual voltage dropped across a semiconductor junction, eliminating all guess work. The test, if performed in-circuit with a parallel resistance greater than 200 Ohms, is completely transparent.

I like all of the 3010's fine features, but my favorite is Insta-Ohms, Beckman's fast, versatile continuity indicator. At the moment of continuity detection, an Ohm symbol is displayed in the upper left-hand corner of the LCD display. With its virtually instantaneous operation, Insta-Ohms has created a wealth of tests never before feasible on a purely digital multimeter, including those with audible indicators. Prompt detection (less than 100 milliseconds) allows the 3010 to accomplish analog-style tests such as checking a capacitor's ability to accept and hold a charge. In this case, the analog needle is replaced by the Insta-Ohms symbol, which appears quickly as the test begins. The charging capacitor's apparent resistance falls within twice the maximum of the selected range.

A readout of the resistance follows almost immediately. The cap's steadily building charge swings the reading upward toward infinity, until a point is reached where one of two things will happen. Depending on the selected resistance range, either the readout and Insta-Ohms will overflow, or a final breakdown value for the capacitor will be found. The necessity for fast electronics in this test becomes obvious when you involve small value caps with their short time constants. The Insta-Ohms speed is such that I have had no problem checking 2.2-uF and smaller tantalums.

Insta-Ohms has several important advantages over ohmmeters and audible continuity indicators. First, with the overload protection of 300 V dc/rms, you don't have to worry about a damaged meter movement or bent and broken needles. Second, as part of the liquid-crystal display, the indicator uses little power, contributing greatly to the meter's two-year battery life. Finally, because it isn't limited to one or two resistance ranges, Insta-Ohms is useful in tracking down high-impedance "shorts." You also have the blessing of not having to use an override switch on large jobs to kill the incessant buzz that drives fellow workers up the wall.

I'm impressed. I think I'll spend the extra bucks.

In that case, you should be glad to hear that the 3010 comes ready to use, having a battery, spare fuse, safety test leads, and operator manual. Beckman's attention to detail and quality carries into their excellent accessories. The awkward-looking test probes are actually comfortable to use. So much so that I never gave them much thought. Nonetheless, they exerted an influence on me, however subtle. This influence became evident when I had the occasion to use a regular pair of test leads on a 240-volt power supply. I was distinctly apprehensive at the time, and the reason why eluded me. I now know the reason: Subconsciously, I missed the added security imparted by the knobby node end of Beckman's safety test leads.

This brings us to the 3010's operator manual. It is one of the best I've seen. Unlike the scant, inept papers some manufacturers try to pawn off as manuals, the Beckman manual is an in-depth, comprehensive guide to the understanding and use of the 3010. Although faulted as being too long, a premise I do not share, the manual is worth the reading effort.

OK, OK, I'm convinced. Well, almost. There has got to be a zinger—you haven't mentioned one bad word about the meter!

Zinger? I don't know if you could classify them as such, but there are a couple of items that I'm a little less than thrilled about. One, and the brunt of my dissatisfaction must fall upon it, is the 3010's built-in tilt-bail. Conceived as a dual-purpose hanger/bench support, the wire bail is all too flimsy for hanging the meter. Its most unforgivable sin of sins is the metal construction which makes it a great conductor and, thus, dangerous.

The only other fault with the 3010 is that you cannot zero the resistance function. This becomes a factor only when using the lowest range, and the resistance of the test probes is displayed. Less than 0.2 of an Ohm in value, my objection centers on the fact that no means of zeroing this reading is provided.

You've made a sale! I can contend with those easily.

Fine—my sentiment exactly. If you want to hunt exotic nonsinusoidal waveforms like triangles and ramps, look into Beckman's RMS 3030—currently the only hand-held DMM with true-rms measurement capability.

MAGAZINE PERSPECTIVE

With much of the ham industry hurting badly for sales, the need for new hams and perhaps for some new interests in amateur radio is apparent. Dealers have been dropping like the fall leaves and manufacturers have been retrenching . . . or going to the SBA for additional loans to tide them over. Over into what is problematical.

In these days of confusion, how are the ham magazines doing? We publishers sit around counting the pages of ads, the pages of articles, the number of articles, and all that sort of thing. That's part of the publishing biz. You may be interested in the counts.

First, looking at 1980, we find that *73* had 290 feature articles to *QST*'s 132. Over twice as many. *73* had 871 pages of articles to *QST*'s 416, again over twice as many. Presumably it is the articles which are of major long-term importance to you rather than club activities and contests. In advertising, *73* averaged 94.8 pages per issue and *QST* 94.9. *HR* came in third with 38.7 pages, then *CQ* with 35.4 pages, and HRH with 22.0 pages, which may help you understand its demise.

Looking at the 1981 January issues of the four remaining ham magazines, we find that the ad count is almost exactly the same as 1980 January . . . which is odd, if the recession in ham sales is true. *73* had 87 pages of ads, *QST* 101 pages, *HR/HRH* 53 pages, and *CQ* 46. *CQ* is up two pages this year, *QST* the same, and *73* down four pages (we have cancelled several pages of ads for slow payments and poor customer service).

Where are things as far as articles are concerned this year? That's what you are buying for the most part . . . not club news and ads. *73* had 25 articles against nine each for *QST* and *HR*, with 8 for *CQ*. In pages of articles, *73* ran 73 pages, *QST* 28, *HR* 44 and *CQ* 18. That does not include monthly columns. Interesting that *73* should run more pages of articles . . . and more articles . . . than *HR* and *QST* combined. It might even make someone think . . . though I doubt it.

PROPINQUITY

If you let your daughter go out with creeps . . . she will marry a creep. And if you have a son and let him date a punk rock weirdo girl, you stand a good chance at having to adjust to this cretin as a daughter-in-law. It all has to do with the not-very-well-understood concept of love.

You've heard about love being blind. Well, you'll believe it when it hits you through one of your children. Of course, how it hits you has a lot to do with how much you control your teenager . . . and control in this sense has to do not so much with trying to stop him or her from dating nerds as preventing the propinquity which gets all of this started. Propinquity is being together . . . nearness . . . such as a being in the same class in school or belonging to the same club. Much as a baby duck will pick whatever it first sees moving as its mother, teenagers, when struck with the right hormones, fall madly in love with almost the first thing they see of the opposite sex.

So, if you have your teenagers in a school full of losers, you might as well start adjusting yourself to accept that whatever they have in class with them is going to get dragged into your life.

I bring this up not to get you to move to Peterborough or to rush your pre-teens to a better class private school, but to make a point about amateur radio. In the love affair a lot of us have with hamming, propinquity is *all*. A basic fact is that before you are going to have many more hams, you are going to have to see that you get a lot of teenagers near to it.

One lousy exposure in a mall on a Sunday is not potent enough in the propinquity department. If you or your club are going to sell amateur radio in this day, you are going to have to bring teenagers into contact with it as much as you can. Remember, you're up against a lot of other interests such as Boy Scouts, roller skating, after school games like baseball . . . things like that. It is most fortunate for us that the amateur radio susceptibility hormone does not hit after puberty, otherwise we'd have no hobby. Luckily for us, this period of impressionability hits hardest at around 13 and 14, before girls start to really look good.

Another nasty competitor for teenage affections is the microcomputer, so you have your work cut out for you. Remember that more and more high schools are getting computers right into class . . . and darned few (if any) are getting ham rigs into class. You are up against a mighty foe in the computer, so you'd better reckon with it and get your act together. It appears that the same faulty brain circuitry which tends a teen to become a ham also can flip him into computers.

We can win this battle only if we are aware of the enemy and play every trick we can to ensnare our share of teenagers . . . or even more than our share. It is time to be greedy and pull our hobby out of the slump it is in.

The key to how to do all this lies in that word, propinquity. It is up to *you* to see that teenagers are exposed repeatedly to amateur radio. Their natural immunity will finally be beaten down and we'll have 'em . . . trapped for a lifetime, for the most part. Insidious hobby we have, when you think about it.

NEWSLETTER CONTEST

To encourage publication of club and group newsletters which, in turn, help spread ham radio interest around the world, *73* is initiating a newsletter competition. So, make sure that *73* is on your mailing list.

Our judges will evaluate each one and pick a monthly winner to be announced in *73*. Each winner will receive our Novice Class Study Guide and theory tapes *or* their choice of three books from the Radio Bookshop. Please address newsletters to *73 Magazine*, Pine Street, Peterborough NH 03458, Attention: Newsletter Contest.

A FREE BOOK FOR YOUR QSL?

That's right. Send us your QSL and we'll enter you in *73*'s QSL of the Month Contest. If yours is selected, it will appear in *73* and you'll be given your choice of a book from our Radio Bookshop. We're looking for clever, colorful, beautiful, neat, interesting, etc., QSLs. Please address your entry to *73 Magazine*, Pine Street, Peterborough NH 03458, Attention: QSL of the Month.

Despite parents' efforts to deprogram our converts, most teenagers go right on to fruitless careers in electronics and communications.

So you get a demo station into your local high school and run it for a few weeks, handing out seductive literature to anyone foolish enough to get sucked into watching. Then you figure out some small bribe to get 'em into your club license classes. You charge 'em enough for the set of classes so their natural stinginess (part of the ham ethic) will prevent them from dropping out. Salt your classes with references to the incredible fun they are going to have once they get their ticket. They're *yours*.

The mall demo won't hurt... and the exercise is good for club members. It's fun to be the center of attention in a mass setting like that... and you'll be able to get a few more into your classes. This will also give you a second flanking attack on the teens, if you have some fast-food stores in the mall. Teens tend to be attracted to fast-food purveyors. Maybe we should approach McDonald's about demo ham stations? I prefer Wendy's myself... it's the salad bar, not the greasy (juicy, they call it) hamburgers.

If you can get teenagers near ham stations enough, we'll have plenty of 'em getting licenses and perhaps amateur radio will get back into a growth mode again.

WAR COLLEGE

Definitely flattering... and tough to turn down. The invitation was to join a group of 70 noted civilians for five days of workshops with the Air War College. This is a group of high-ranking Air Force officers who have gone back to school to bone up on the latest in military hardware, tactics, intelligence, and so on. At the end of the course they have five days of discussions with selected civilians.

The problem was the five days. I don't *have* five days. Of course, not having been to one of these affairs, I don't know how much interest there is in getting ideas from the civilians and how much is brainwash from the military. All of my visits to the Pentagon so far have given me the impression that none of the military services wants input... they just want to lay propaganda on the media for their own benefit.

If they do have any interest in getting some of their problems solved, I think I have some ideas for them which will go a long way. For instance, it is no secret that all of the military services are hurting for technical people. Well, getting 'em

Two-Meter Antennas: Facts and Fables

—the truth about omnidirectional antennas on two

Vertical antennas, especially for VHF, come in a wide variety of shapes, sizes, specifications, and price. Manufacturers' gain claims have created such confusion that one of the popular magazines does not allow an antenna manufacturer to publish gains in their ads, and magazine reviews rarely say more than "the antenna worked great." This only exacerbates the problem because we, the users/consumers, have no way of getting reasonable relative performance information short of listening to someone tell us how wonderful his great new XY-999**!* antenna is, or through the grapevine of information formed by our "oral tradition." This is where the fable part comes in. We all know how well a joke gets passed around a room when one person whispers it into the ear of the next. It usually is unrecognizable after passing through as few as a half-dozen people. This is the same way we get our information on antennas, and often the quality of that information resembles a joke!

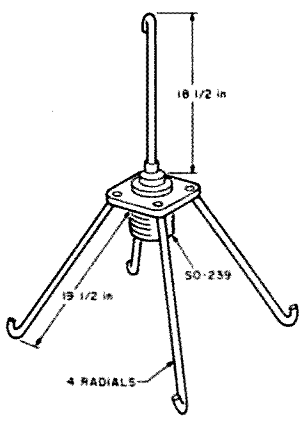

Fig. 1. Simple 1/4λ 2-meter ground-plane antenna.

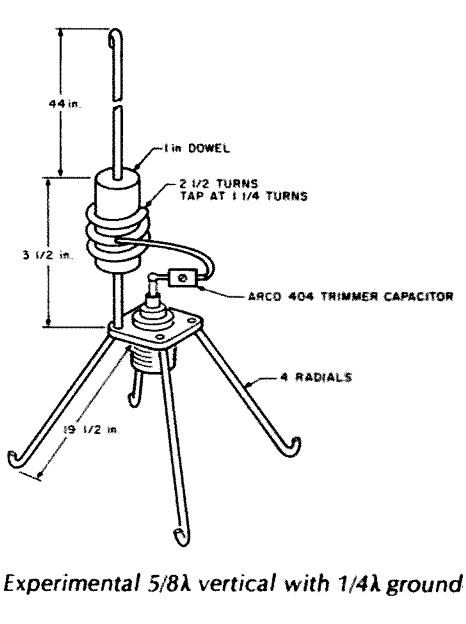

Fig. 2. Experimental 5/8λ vertical with 1/4λ ground plane.

I realized this recently when I was selling an old 2-meter rig to a friend and I wanted to make up a simple antenna so that he could use it right away. I have used the makeshift 1/4λ ground-plane antenna shown in Fig. 1 several times (it costs one SO-239 plus a few cents worth of old house wiring) and I was about to make one for him when I remembered something "we all know"—a 5/8λ antenna has 3 dB gain over a 1/4λ ground plane. Now, having purchased one of those more years ago than I

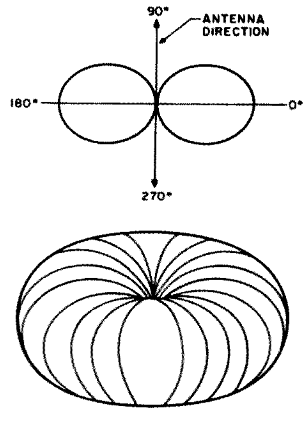

Fig. 3. Radiation pattern representations of 1/2λ dipole antenna. Top—typical plot, cutaway; bottom—three dimensional sketch of toroidal radiation pattern.

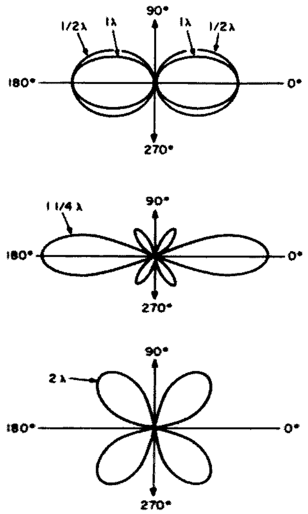

Fig. 4. Radiation patterns for vertical dipole antennas of different lengths. The narrower major lobes of the 1λ and 1-1/4λ antennas imply gain over the 1/2λ antenna.

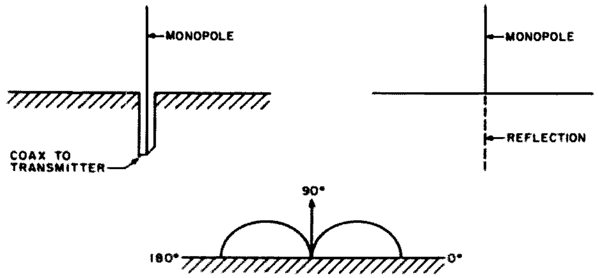

Fig. 5. Ideal vertical and its radiation pattern. Left—vertical monopole over infinite perfectly-conducting ground. Note that the coax shield is in electrical contact with the ground. Right—electrical equivalent is a virtual dipole whose other half is a reflection in the mirror formed by the ground. Bottom—theoretical radiation pattern for 1/4λ vertical monopole over ideal ground plane.

like to admit, I noted that it had four 1/4λ radials, a matching section, and a 5/8λ radiator, so I built the antenna shown in Fig. 2. It tuned up to 1:1 swr so quickly that I was sure it was working great. I put it on the air, and sure enough I was getting out. But, since I live on a fair-sized hill not all that far from repeater alley in the Boston area, I had no way of knowing for sure whether this antenna was really better than the 1/4λ ground plane.

Of course, everyone knows that the 5/8λ is better than a 1/4λ—even some of the antenna manufacturers' literature says so—but isn't that part of our fable? Anyway, I decided to perform a simple experiment by comparing the two antennas in exactly the same place using the signals from the various repeaters and the meter on my KDK 2016A to measure the relative performance. (I later discovered that this is called reciprocal testing: using a distant signal source and the antenna under test in the receive mode.)

The results of this test were baffling—the 1/4λ outperformed the 5/8λ in every direction! Surely something was wrong with my test, so I asked some of the guys in the area to give me signal reports with the two antennas. I used the same feedline and mount for each, so I had to run out and physically remove one antenna and install the other to do the comparison. The results were the same; reciprocity was proved again! (The reciprocity principle states that the relative performance of an antenna as a transmitting antenna and as a receiving antenna is identical.) Was our oral tradition wrong? Something surely was, so I dug into manuals and textbooks to find out the answer. Here is some of what I discovered.

The Applicable Antenna Theory

First, consider the question: How can an antenna have gain? In order to answer this one must also ask: What is our reference for measuring an antenna's gain? Two references are used as a base for measuring an antenna's gain. The first, an abstract notion used in theoretical computations of antenna performance, is the so-called isotropic radiator. This is a hypothetical device which radiates energy equally in all directions simultaneously with a spherical pattern. However, to make real measurements with real antennas, the usual reference is a half-wave dipole in free space.

The free-space dipole has a figure 8 radiation pattern in the plane perpendicular to the antenna and a circular pattern of equal radiation in all directions radial to the axis of the dipole as shown in Fig. 3. Now, the gain of an antenna is defined as the ratio of the magnitude of the maximum radiation to average radiation from the antenna in all directions if the losses in the antenna are negligible. The maximum lobe for gain measurement is independent of the direction of that lobe. The gain is diminished by the amount of losses in the antenna. (G = maximum radiation intensity divided by average radiation intensity.)

Note that the average radiation in all directions is the same as that from an isotropic radiator, which is why it makes such a good conceptual reference. The dipole has a theoretical gain of 2.15 dB as defined above, so we can say that a dipole has 2.15 dB gain over an isotropic radiator. (An isotropic radiator is only a theoretical notion and cannot be built anyway.) Now, when we use a dipole as a reference when studying some other antenna, we only need to add 2.15 dB to our measurements to reference our subject antenna's performance to an isotropic radiator. The gain or loss in decibels of a reference antenna with respect to a dipole is often written as dBD.

Before we consider verticals specifically, let's look at the radiation patterns generated by dipoles whose lengths are greater than 1/2λ as shown in Fig. 4. Note that the pattern radial to the axis of the antenna is symmetrical. The longer the antenna gets up to 1-1/4λ the narrower the major lobes get, which means higher gain. Beyond 1-1/4λ there are four major lobes which point more towards the ends of the antenna than perpendicular to it.

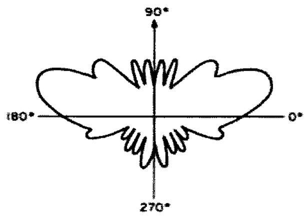

Fig. 6. Radiation pattern of a monopole approximately 1/4λ long over a 6λ circular ground plane. Note that the major lobe is above the horizon.

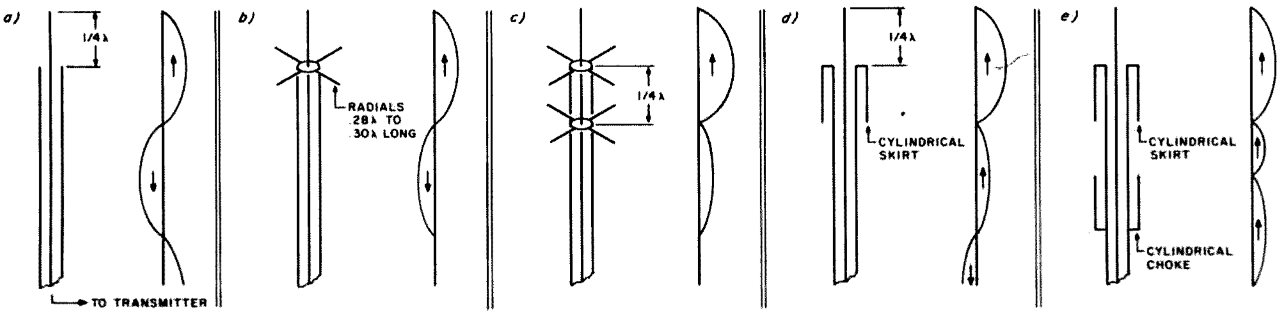

Fig. 7. Configurations and current distributions for several different vertical antennas. (a) Without ground plane. Outer conductor of coax provides radiating return path for rf. (b) With 1/4λ ground plane. Note current 1/4λ below ground plane is mostly in image. (c) With two ground planes, one 1/4λ below the other, providing excellent isolation of feedline radiation. (d) Coaxial 1/2λ dipole. (e) Coaxial 1/2λ dipole with choke to isolate the antenna from the mast.

Now, one can also erect a vertical dipole and consider the 0°-180° line as the horizon and reconsider the patterns in Fig. 4. It should be clear that the 1-1/4λ dipole puts more energy on the horizon than the other length vertical dipoles. Maximum lobes on the horizon are generally assumed to be the most desirable for both DX and VHF communications. The 1-1/4λ dipole has a typical measured gain of 3 dB over a 1/2λ dipole.

Now let's look at the classical description of a monopole or single-element vertical. A single vertical radiator must have a path through which the antenna return currents can flow, so a monopole is usually described with respect to an infinite, perfectly-conductive sheet or ground plane. See Fig. 5, top left. The ground plane carries the other half of the antenna current and mirrors the monopole (Fig. 5, top right), creating a virtual dipole across the ground plane. The radiation pattern is precisely one half of the pattern of the dipole whose leg length is the same as the length of the monopole as in Fig. 5, center. Thus, the 1/4λ monopole has the upper (or lower) 1/2 of the radiation pattern of a 1/2λ dipole.

All this is well and good, but how many infinite, perfectly-conductive sheets are there and what happens if the sheet is not infinite or not perfectly conducting? There have been no reports, to my knowledge, of the discovery of an infinite, perfectly-conductive sheet, so let's examine what happens if the ground plane is merely some finite, physically-realizable size. Interestingly, the size of the conductive sheet has little effect on the impedance of the antenna but has a significant effect on the radiation pattern. As the size of the ground plane gets smaller, the mirror for the monopole gets "cloudy" and the reflection of the image diminishes. The result is a higher angle of maximum radiation than that supplied by an infinite ground plane as shown in Fig. 6 for a 1/4λ monopole over a 6λ-diameter conductive sheet.

This provides the first clue to the poor performance of the 5/8λ antenna over a 1/4λ set of radials. It also raises some questions concerning the use of an auto body as the ground plane for any antenna on bands below 1296 MHz. In fact, the pattern and gain for any auto antenna needing a ground plane is very unpredictable—you get what you get! There are auto antennas which do not use the auto body as a ground plane which do provide predictable radiation patterns and gains for VHF use. On the other hand, a ground-mounted antenna over a large number of buried radials is indeed a reasonable approximation to an ideal monopole over an infinite ground plane, but ground losses can reduce the performance over that of a dipole if the ground is lossy and/or there is an insufficient number of radials.

AM broadcast stations use ground-mounted vertical antennas very effectively with ground systems of at least 120 wires at least 1/4λ long buried radially from the base of the antenna and connected to the shield of the coaxial feedline at the base of the monopole. The larger the number and the longer the length of the radials, the lower the ground system resistance and hence the lower the ground losses. The resistance of a good ground system is about 2 Ohms which, for an antenna whose radiation resistance is about 40 Ohms, is not an insignificant loss. So, if your trap vertical sitting in your back yard isn't getting out as well as you would like, try adding more and/or longer radials where the trade-off is usually for more rather than longer. Better yet, put it on the roof as high as possible to reduce ground losses and do better on the high frequencies as well.

For VHF, say 2 meters, we all know that the height of the antenna is very important (although it has been my experience that on all bands above 160 meters the height of the antenna is more important than any other single parameter) so we prefer to mount our antennas on tops of buildings, towers, poles, trees, etc., to get them as high as we can. One could mount a vertical radiating element on the end of the feedline as in Fig. 7 and depend on the mounting structure and feedline for the ground return. This kind of an antenna will work, but its performance is unpredictable since it depends on the lengths and positions of both the feedline and mounting structure for the radiation pattern it provides. This is because the feedline and mounting structure carry the radiating ground-return currents.

A typical current distribution on the outside of the

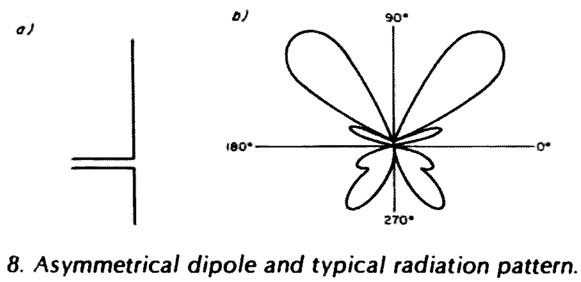

Fig. 8. Asymmetrical dipole and typical radiation pattern.

coax feedline is also shown in Fig. 7. Note that the phase of the current on the outside of the coax reverses at 1/4λ below the top element. This will tend to cancel the effect of the top half wave of the antenna and distort the pattern from that of either the ideal vertical or a dipole in free space. The conductive sheet or mirror can be simulated by wires extending horizontally from the base.

The concept of a mirror formed by wires can be understood easily by first considering a vertical 1/4λ element with a single 1/4λ radial. This forms a bent dipole, a rotated inverted vee, with both horizontal and vertical polarization. If we distribute three or more radials symmetrically about the base of the vertical element, the horizontal components of the radiation from the ground plane will cancel leaving only the vertical component of the radiation. The ground plane performs two key functions. It forms a mirror for the vertical radiating element and provides some isolation of the outside of the feedline from the radiating currents.

Typically, four radial wires slightly greater than 1/4λ long form the ground plane, as in Fig. 7(b). Also, the radials are often bent down to pull the radiation pattern more towards the horizon, as in Fig. 1. This also raises the impedance a bit closer to 50 Ohms. A properly adjusted vertical ground-plane antenna looks very much like a 1/2λ dipole with respect to its radiation pattern and gain—approximately 0.1 dB less. A further refinement of the ground-plane antenna, shown in Fig. 7(c), places an additional ground plane 1/4λ below the first one to act as a choke, which improves the radiation pattern by further reducing the current on the outside of the feedline. A similar result can be obtained by using 1/4λ sleeves instead of a ground plane, as shown in Figs. 7(d) and 7(e) to create a coaxial or sleeve antenna.

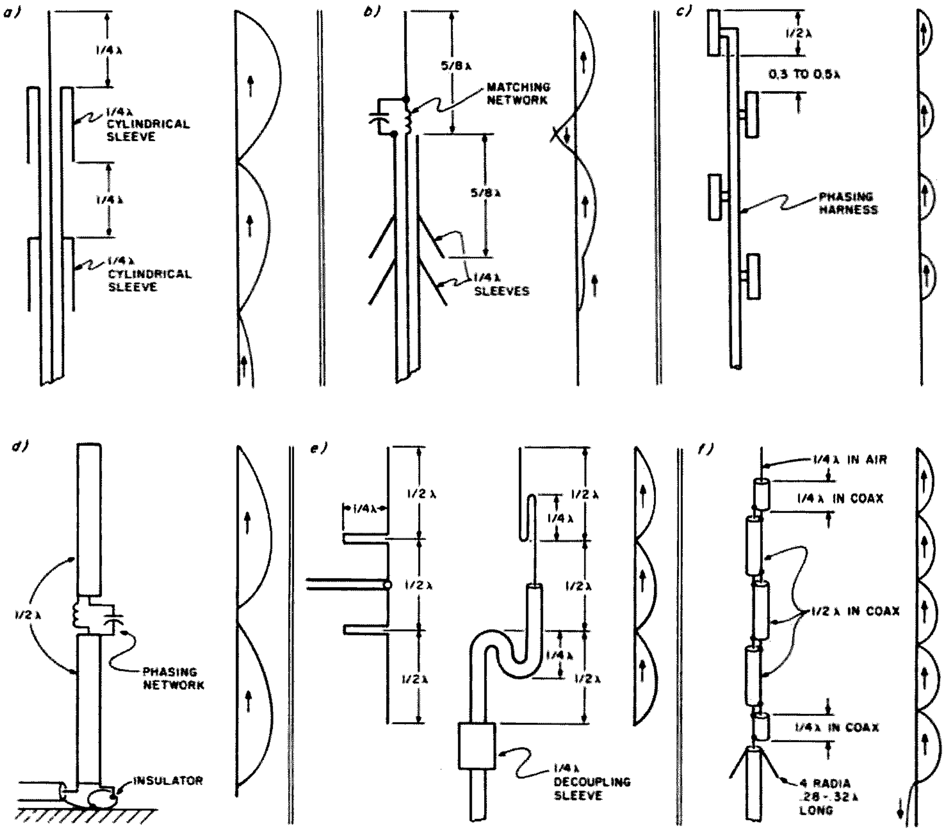

Fig. 9. Several omnidirectional vertical gain antennas and their current distributions. Arrows show phase of current; antennas with the most current in phase have the highest gain. (a) Skirted, to phase feedline currents to form a collinear antenna—1-2 dBD. (b) Isopole, using sleeves to phase feedline currents to form 1-1/4λ dipole and to isolate it from the mast and feedline—3 dBD. (c) Four collinear folded 1/2λ dipoles fed with a phasing harness. Four elements provide 6 dBD omnidirectionally and 9 dBD unidirectionally. (d) Ground-mounted collinear. The 1/2λ sections are insulated from both ground and each other. An LC network provides the phase shift needed to get currents in phase in the two sections—2 dBD. (e) Franklin antenna—dipole and coaxial versions. The 1/2λ stubs provide the phasing for current in adjacent sections. Three sections above—3 dBD. (f) Coaxial collinear uses sections of coax arranged so that the radiation from the outside of the coax is properly phased. Gain is proportional to the number of 1/2λ sections. Eight 1/2λ sections—6 dBD.

The outside of the sleeve acts as a conductor for the return signal while the inside is a shorted 1/4λ transmission line with a high impedance at the open end. The current distribution for both the ground-plane and sleeve antennas is identical to that for the vertical dipole. If one mounts a longer vertical element such as a 5/8λ on the 1/4λ ground plane or 1/4λ sleeve, then we have an asymmetrical dipole equivalent which has a pattern with multiple high-angle major lobes as shown in Fig. 8. This antenna does not work well to the horizon and we have the truth—the end of our fable. Then how do we get the 3-dB theoretical gain from a 5/8λ antenna? We probably do get it but in a direction above the horizon which doesn't do much good. Then how do we get the signal where it does do some good?

First, we *know* that we get 3-dB gain over a 1/2λ dipole with a 1-1/4λ dipole, so a vertical dipole which is 1-1/4λ long will do it in a direction which gets out where we want it. An equivalent can also be obtained by using an appropriate ground plane which properly mirrors the radiator. For example, ground-mounting a 5/8λ element over ground with high conductivity as well as a good ground radial system is one way. A ground plane with 5/8λ radials will also provide the 3-dB gain. Another approach, taken by AEA with their Isopole™, uses a 1-1/4λ sleeve dipole with a second isolation sleeve, as illustrated in Fig. 9(b).

The 1/4λ sleeve on the sleeve antennas and the

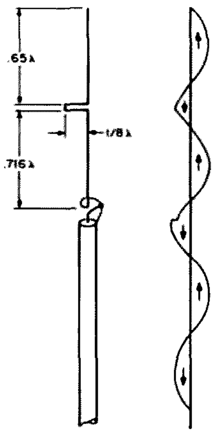

Fig. 10. Ringo Ranger and its current distribution on both the monopole and the feedline.

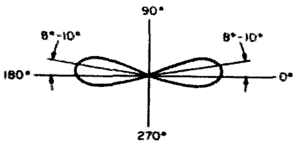

Fig. 11. Radiation pattern of the Ringo Ranger, from the manufacturer's literature. Note that the major lobes are 8°-10° above the horizon.

Isopole ensures the proper phase for the remaining current on the outside of the coax while minimizing that very current, thus ensuring that the radiation pattern is both predictable and on the horizon. The double-sleeve antenna, Fig. 9(a), is a simple collinear which provides 1- to 2-dB gain over a 1/2λ dipole because of the proper phasing of the small current which does flow on the outside of the coax. The addition of more than two sleeves does little to improve the gain because the current below the second sleeve is very small. Other types of collinear antennas can provide additional gain as shown in Fig. 9, with the gain over a dipole, dBD, provided in the caption. The basic objective for obtaining gain is to provide multiple radiating elements in which the currents are as large as possible and in phase.

The phasing can be obtained by:

- Using feedline currents as in the sleeve collinear in Fig. 9(a), as described earlier.
- Spacing the radiating elements as in the collinear dipole in Fig. 9(c).
- Using lumped L and C phasing networks as is done for the low-frequency ground-mounted antennas in Fig. 9(d).
- Folding a half wave of wire or cable up as in the Franklin antenna in Fig. 9(e). Note that folding is also used to provide loading in beams, in particular 40-meter beams and the KLM KT34A and KT34XA triband beams.
- Using alternate 1/2λ sections of coax connected so that the current on the outside of the coax elements is radiating in phase, as in the coax vertical in Fig. 9(f).

Some comments on these various phasing techniques will illustrate the relative merits and trade-offs in these different designs.

Number of 1/2λ Elements	A Close Spacing	B Optimum Spacing
2	2.0 dB	3.1 dB
3	3.0	
4	4.0	6.2

6		
7	5-7	
8	6-8	9.3

Table 1. Gain of collinear antennas consisting of 1/2λ sections for close and optimum, 0.3λ to 0.5λ, spacing for different numbers of 1/2λ sections. The close-spaced numbers are approximate and depend on the type of antenna.

First, spacing four or more folded dipoles as in Fig. 9(c) is a straightforward way to provide phased current flow. The optimum spacing for collinear arrays, between 0.3λ and 0.5λ, is easily obtained by placing the dipoles on a vertical mast. This type of antenna will provide single directional gain of 9 dBD by placing all the dipoles on that side of the mast, or 6 dBD omnidirectional gain by distributing the dipoles around the mast. A phasing harness is required to distribute power to the dipoles in the proper phase. (Details for building such an antenna for 2 meters are given in Reference 2.)

Gain from a low-frequency ground-mounted vertical with a radial system may be obtained by either making it 5/8λ long or by stacking two 1/2λ sections on top of each other, with insulators between the sections. The sections are coupled through an LC network so that the currents in the two sections are in phase; see Fig. 9(d). Since the spacing between the 1/2λ sections is not optimum, the gain is less than one would get if they were spaced 0.3λ to 0.5λ apart. The gain of collinears for different numbers of 1/2λ elements for close and optimum spacing is given in Table 1.

The Franklin antenna uses a folded section in the monopole so that the radiation from that length is cancelled and the currents on the radiating parts of the antenna are in phase. The outside of the coax feedline carries the radiating return currents. The coax is also folded to ensure that currents on all sections of the coax are in phase with each other and the radiating sections of the monopole. Again, the spacing between sections is not optimum, so approximate gain is given in column A of Table 1.

The coaxial collinear, Fig. 9(f), is an antenna that has become very popular as a repeater antenna because it can provide good omnidirectional gain (6-9 dBD) and is relatively easy to make. It can be thought of as the ultimate in using the feedline as a radiator. The goal of the design is to propagate the signal through the coax in 1/2λ sections so that the outer conductors of the coax sections carry a current which radiates. Remembering that electrical 1/2λ in coax depends on the propagation velocity of the cable and is always less than the free-space length, this is accomplished by connecting the 1/2λ sections of coax so that the shield of one section connects to the center conductor of the adjacent section, thus ensuring that the coax radiates a signal which is in phase with that in the adjacent section. Any number of 1/2λ sections can be used with more sections providing more gain. The gain is limited, however, by the fact that the current diminishes as the signal propagates up the antenna, since each section radiates some of the applied energy. Also, the close spacing of the sections further limits the gain. Thus, the gain shown in Table 1 for this antenna can be obtained by considering the number of 1/2λ sections only and not counting the top and bottom sections even though they do radiate. The bottom 1/4λ section ensures the proper phasing for the current fed to the first 1/2λ section. The 1/4λ ground plane on the bottom, which often is replaced by a balun, provides an image for the 1/4λ section and isolates the feedline from the antenna. The top section terminates the wave propagating up the antenna so that the phasing is preserved and the last 1/2λ of radiation occurs.

Coaxial collinears can be mounted either in fiber-

glass radomes on top of a mast or suspended from the side of a tower inside plastic drain pipe. The only difficulty is that the lower sections which carry the greatest radiating current are closest to the ground. See Reference 2 for further information on this antenna.

Performance

Now that the theoretical basis for the poor performance of my homemade 5/8λ antenna was established, I decided to test some of the other popular 2-meter antennas on my simple test setup. Probably the most popular and easiest to use 2-meter base-station antennas are the Ringo™ and Ringo Ranger™ by Cushcraft. The Ringo is described by the manufacturer as a 1/2λ monopole while the Ringo Ranger is described as two 1/2λ elements in phase. The physical dimensions of the Ringo Ranger indicate that it is really a bit longer than 1/2λ, as shown in Fig. 10. Also, the phasing stub is 1/8λ rather than 1/4λ as in the Franklin collinear and is located so that the higher-current portions of the reverse antenna current are in the stub, also as shown in Fig. 10. Also note that the phasing is such that the feedline and/or mounting structure are carrying radiating current. Since this current is not specifically phased, and because the phasing stub is 1/4λ rather than 1/2λ, some compromise in on-the-horizon performance appears to have been made to get a solid, simple antenna. The extra out-of-phase current is probably responsible for the slight elevation of the radiation pattern (about 9 degrees) as given in the manufacturer's literature reproduced in Fig. 11. Thus, one may expect that the Ringo and Ringo Ranger on-the-horizon performance would be less than that of some other antennas and that their performance may be improved by adding a ground plane.

Well, armed with my SO-239, 1/4λ ground plane, my home-brew 5/8λ on the 1/4λ ground plane, a Ringo, a Ringo Ranger, a Ringo Ranger with six 19-1/2-inch radials drooping at 45°, and an Isopole, I went out in the cold of February to find out what worked best.

Note that radials made from aluminum ground wire can be added to the Ringo or Ringo Ranger easily by bending three 40-inch pieces of aluminum ground wire around self-tapping screws in the base of the antenna making six 19-1/2-inch radials. The radials have a negligible affect on tuning.

I used the same testing techniques I had used earlier—measuring the relative received strengths of repeaters and locals in all directions and getting signal reports from locals. The data taken for each station were then normalized by dividing the reading for the best antenna into the readings for each antenna. I then averaged the normalized numbers for all stations for each antenna. This allowed me to get an unbiased relative performance metric across each antenna. The results are plotted in Fig. 12 for received signals from both repeaters, which tend to be at higher elevations around me, and local stations. The averaged values in each direction for signals from repeaters also are plotted. Basically, Fig. 12 indicates that neither direction nor elevation affects the relative performance of these antennas tested at my location, and that the Isopole is the best of the antennas tested. The rest of the antennas were tested with the original four and the results in both receiving and transmit modes are given in Fig. 13. Again, the results are consistent.

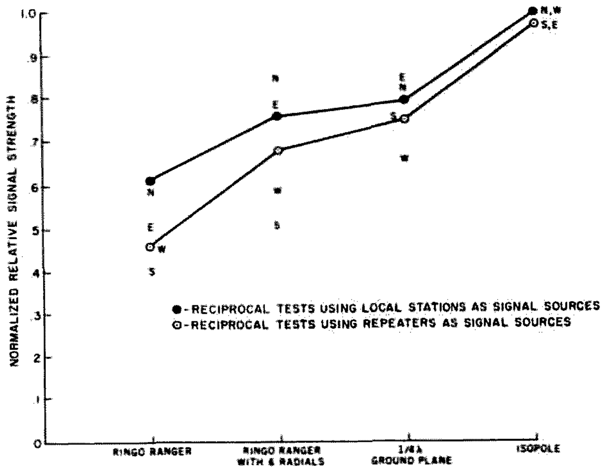

Fig. 12. Relative signal strength of four antennas for repeaters and local stations in different directions. Normalized strengths for each direction are given by N, S, E, and W.

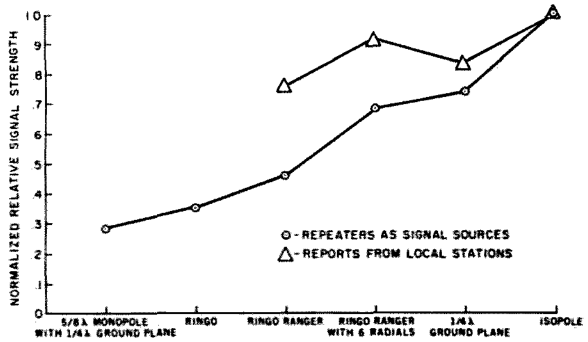

Fig. 13. Relative signal strengths of six antennas in both transmit and receive modes. Wider variance from reports from other stations is expected because S-meters are independently calibrated.

Conclusions

From these tests it is clear that:

1) The 5/8λ radiator on a 1/4λ ground plane is a poor antenna—do not bother with it.

2) The 1/4λ cheap (less than $2.00) SO-239 ground-plane antenna of Fig. 1 is a very cost-effective antenna.

3) Radials do improve the performance of the Ringo Ranger.

4) The Isopole performed better than all the other antennas in almost every case.

It is interesting to note that since these tests were run, Cushcraft has come out with a decoupling kit consisting of a ground plane which mounts some distance below the base of the Ringo Ranger to improve its performance. I will try it as soon as I can get one to my test site.

The 440-MHz Curtain

—hang this broadbanded two-bay collinear on your tower and get 22 dBi to play with

I had been experimenting for several years with various antennas on a UHF repeater, trying to obtain reliable coverage over a 50-mile path. Initially, I used arrays of commercially manufactured yagis with good but not spectacular results, eventually ending up with an array of eight 14-element yagis stacked vertically up the side of the tower.

I began to suspect that something was amiss after removing four, then six, yagis from the array, leaving just two and discovering that signals didn't drop the expected 6 dB. In fact, I observed closer to a 3-dB difference between two and eight yagis.

Experimenting further, I found little effective signal gain between four and eight yagis. I was stumped over this discrepancy until I thought of the losses at 440 MHz of four additional baluns, a four-way splitter, a two-way splitter, some 30' of RG-8, and ten coax connectors!

Photo A. Construction details.

While mulling over different ways to pick up those elusive dBs, an antenna with a whole lot of relatively inexpensive gain came to mind. This was a broadband, high-gain (21.3-22.8-dBi) curtain array used by the VOA in the 9- and 11-MHz shortwave bands for optimum signal into overseas locations.[1] The VOA dumps about 200 kW into such an array and the resulting 20-megawatt erp usually gets the message across. This antenna is a two-bay collinear, with eight half waves per bay, spaced a quarter wave in front of a screen reflector.

When scaled to UHF, the proportions become entirely manageable. I'll be describing an array based on this design consisting of three bays of six elements, occupying a space of about 3-1/2' × 8' and a total material cost of about $20. As opposed to a yagi, a collinear is easy to tune and is almost guaranteed to work well right off the bat.

The framework for the array is made of 2" × 2" pressure-treated lumber for weatherability—redwood or cedar would be excellent alternatives. Assemble the frame using a sufficient number of corner irons and screws to impart rigidity to the structure. The plane reflector is made of so-called chicken wire fencing stapled to the front of the frame. This material is galvanized, light weight, strong, a near-perfect UHF reflector, and has low wind resistance.

Don't substitute ordinary window screening or hardware cloth in temperate climates as the holes will fill with snow and ice causing one heck of a windloading problem. Either the antenna mount would fail during a winter storm or you might find your tower becoming a giant fly swatter. You want to stretch this fencing as much as possible while stapling it to the perimeter of the frame so that it won't flap in the wind.

Once the framework is assembled, the next step is to attach the pre-drilled struts that hold the driven elements in place. I used 3/4" × 1/2" stock in a crossbar arrangement. No insulation is required in mounting the elements this way as the rf voltage at the center of the elements is minimal. The elements are made of #12 copperweld antenna

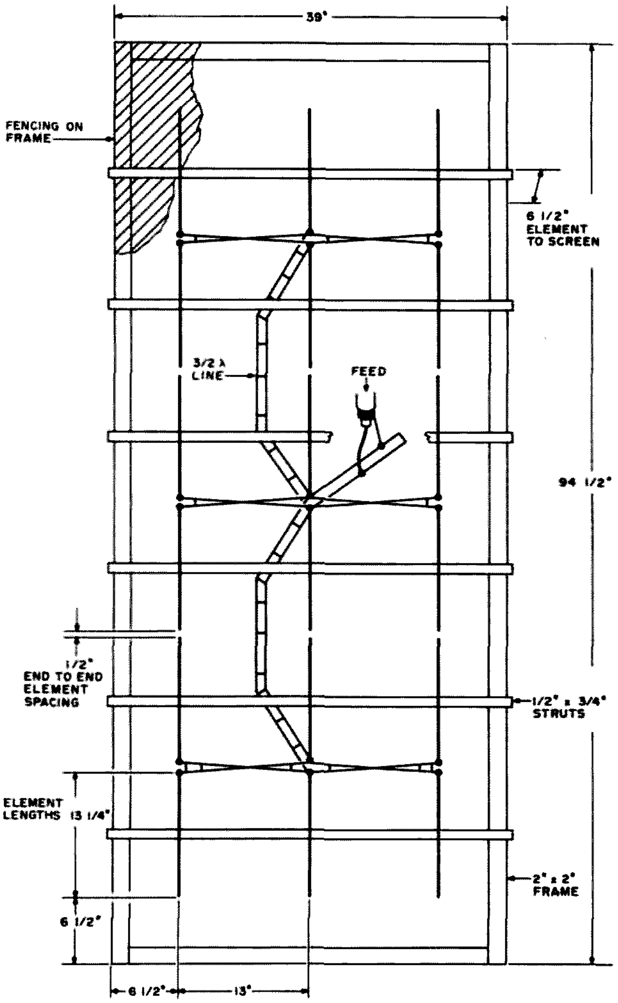

Fig. 1. 440-MHz array construction details.

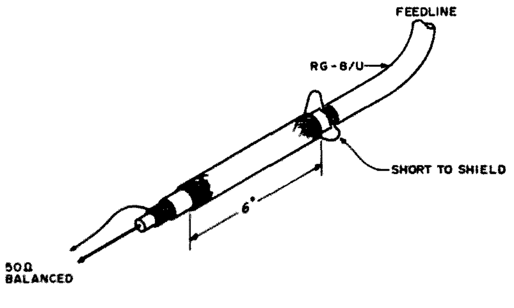

Fig. 2. Details of sleeve balun construction.

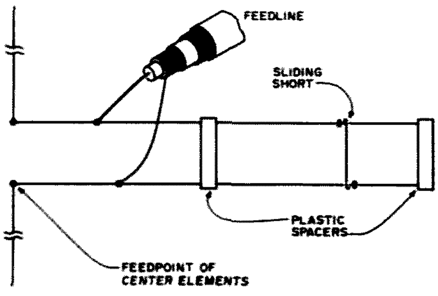

Fig. 3. Universal stub construction.

wire inserted through drilled holes in the cross-bars and held in place with silicone RTV. Center the elements in the struts and apply the RTV. Let the RTV dry for a day or so before proceeding further. It's worth applying several coats of urethane or spar varnish to the struts at this point.

Now you should cut the phasing lines to length that connect the elements and bays together. This is the most critical part of construction and requires attention to detail. I made my phasing lines from 300-Ohm Saxton open-wire transmission line, available from several retailers of amateur equipment. This line is #18, spaced 1/2", and I measured its velocity factor as 0.985 in small sections at UHF frequencies.

Please don't use any kind of ordinary twinlead for a harness and expect a decent swr in wet weather. If you must, make your own open-wire line with low-loss spacers. You need three 1λ lines, one for each bay, and two 1-1/2λ lines to interconnect the bays. The 1λ lines are cut to a length of 26-1/4" and the 1-1/2λ lines were cut to 39-3/8" long. Measure carefully!

Solder the phasing lines to each bay. Find the exact center point of a 1λ line and solder this point to the center two elements in a bay. Put a 180° twist in the free ends and solder these to the outside elements, doing the same for all three bays. Now interconnect the three bays with the 3/2λ lines. Loop these lines between the bays and the reflector and don't forget the 180° twist in them before soldering. It's not a bad idea to use a couple of plastic standoffs on these lines, supporting them about 2" above the reflector to keep them from flapping in the wind. Check that the spacing between line conductors is constant and that the lines are generally balanced and symmetrical with respect to the reflector.

This antenna is fed with a 1/2λ universal stub and coaxial sleeve balun. If you're into Q-sections, one also could be used to match a coax line to this antenna's approximately 100-Ohm feedpoint impedance as an alternative. The sleeve balun (Fig. 2) is constructed by cutting off a 6" piece of braid from some RG-8, tinning the ends to prevent unraveling, and slipping it over the end of the coax feeder. The inside end is soldered to the shield of the RG-8 feedline at a point about 6-1/2" from the end where a 1/4" section of jacket has been removed.

Slather some RTV over this connection and the open end of the coax to prevent moisture penetration after stripping and tinning about 1/2" of the coax end. The 1/2λ stub (Fig.3) is 13-1/2" long and can be conveniently made out of the same copperweld that the elements are made of and some spacers from the open-wire line. Heat the wire with a hot soldering iron and the plastic spread-

Gain Calculation

Calculating the gain of a collinear with a large number of elements can be as complicated as you want to make it. A general rule of thumb for the gain of a collinear aimed at the horizon is 4N, where N is the number of half-wave elements. For instance, a 12-element antenna would have a power gain of 48, or 16.8 dB. (Add 3 dB if a reflector is used.) This figure is strictly a rough estimate, and factors such as ground-reflection gain (or loss) or dielectric and resistance losses can change things considerably. (See *Antenna Theory and Design*, Williams, 1950.)

ers can be easily pressed on or off. A sliding short is made from a piece of #18 tightly twisted around both stub lines. A loose fit here will cause erratic readings while tuning.

You must tune this antenna outdoors aiming it up at the open sky. I had this antenna aimed out at the road in front of my house and every time a car went by the swr went up and down! The tuning process consists of alternately sliding the attachment point for the feedline and the short up and down the stub until the best match is obtained. The optimum point for the short will be near the far end of the stub, and the coax will attach to a point about 1" from where the stub connects to the antenna. A 1.5:1 swr was easily obtained. The antenna's bandwidth is excellent and exhibits a good swr over 5 MHz.

Put simply, this antenna is a real band smoker. Using a calibrated signal generator as a reference and the S-meter of a Drake UV-3 60 miles from a repeater using this array, I made some comparison checks. I measured a 12- to 13-dB improvement over a commercially manufactured 20' long, 10-dB gain fiberglass-type omni on the same tower! This is the difference between a signal just barely opening squelch and one of perfect readability with a little background hiss. The beamwidth appears to be on the order of 20° to 25° and the front-to-back and front-to-side ratios are superb. The close bay spacing produces a very clean pattern.

Now, let's see. A half wave on 29.6 is . . . ■

Interest in reception of microwave signals from geostationary orbiting satellites has spread rapidly throughout the amateur community. Some amateurs wish to receive TV programs directly from satellites such as Satcom.[1] Others, like my son and I, are more fascinated by receiving weather pictures from the meteorological satellite, GOES.[2]

Wherever your interest may lie, sooner or later we

all encounter the same problems. To receive weak microwave signals, first, a large parabolic reflector, or dish, must be used for an antenna.[3] Second, this dish must be positioned with a fair degree of accuracy and must be mounted securely enough so that it cannot be blown over by an energetic wind. Finally, for the avid experimenters trying to work more than one satellite, one must be able to move the aim of this unwieldy saucer from one point in the sky to another.

Considering that eventually we would use our newly acquired dish for more than one satellite, my son and I decided to build a steerable mount that could be remotely controlled from our electronics lab in the house.

Photo B. Close up of the azimuth steering arm and control cylinder.

The final product of several designs provided a mount that can be reproduced easily by the average amateur. Costs will vary, depending on your resourcefulness, but with careful shopping this mount can be constructed for less than $500.

The mount is hydraulically operated with an elevation range from 46° to 59° and an azimuth scan of 96°. This range of travel covers most of the usable area of view for equatorial satellites from our location. Photos A and B show the completed mount holding a two-meter (7-foot) dish at our station. The remote control panel, located in the electronics lab, is shown in Photo C.

This article will provide complete construction plans for the mount and controls. Although this project can be built using only hand tools and an electric drill, having access to a power hacksaw and a welder will greatly expedite construction and save many kilocalories worth of elbow grease.

A-Frame

The major portion of the mount is constructed of 3" × 3" × ¼" angle iron. Two eight-foot, and one seven-foot length are bolted together to form an A-shaped frame. The lower ends of this A-frame pivot on two pads that serve as the eleva-

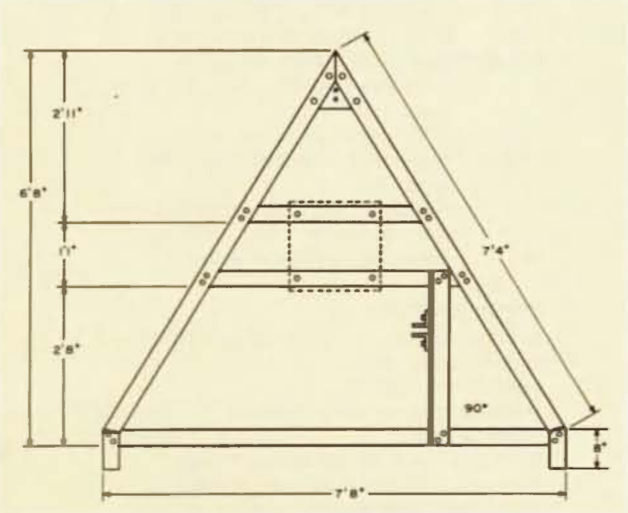

Fig. 1(a). Top view of the A-frame assembly. The dotted line is the location of the pivot frame mounting surface.

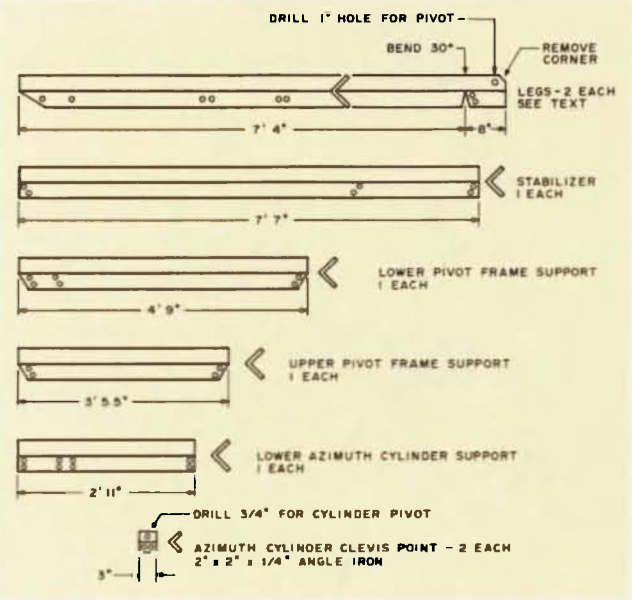

Fig. 1(b). Cutting detail for the A-frame members (see text). All angle iron is 3" × 3" × ¼" unless noted. All bolt holes are ½" unless noted.

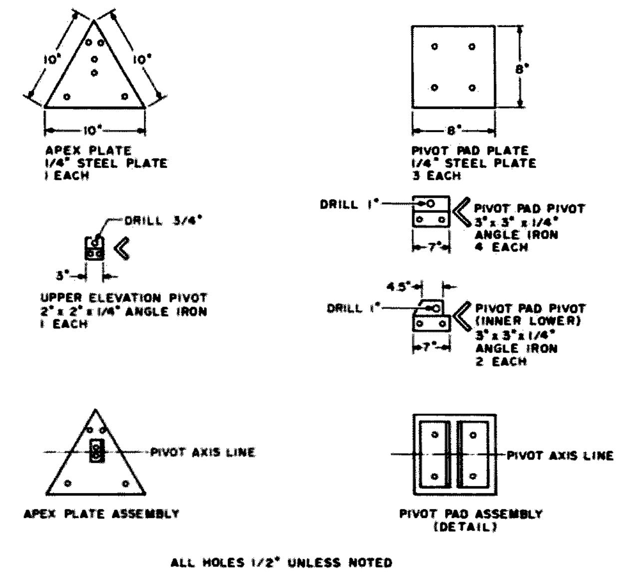

Fig. 2. Apex plate and pivot pad cutting and assembly detail.

tion pivot points. Elevation motion is provided by a hydraulic cylinder extending from the apex of the legs to a third pad. Fig. 1 shows cutting and assembly details for the A-frame. Pivot pad detail is shown in Fig. 2.

A 30-degree wedge must be removed from one side of each of the two legs at a point 8" from one end. The short ends are then bent to close the opening left by the removed wedge. The seams formed at these bends must be closed by welding or by the addition of a web plate bolted over the seams. *Remember*: The cuts must be made so that one leg is the mirror image of the other. The seven-foot length is used as a stabilizer across the bottom of the A-frame.

The pivot pads are constructed from three pieces of ¼" steel plate 8" square and six pieces of 3" × 3" × ¼" angle iron 7" in length. See Fig. 2. Two of these pivots are located at the foot of each leg and one at the lower end of the elevation cylinder.

At the apex of the A-frame a triangular plate of ¼" steel 10" on each side is used for the dual purpose of joining the upper ends of the A-frame and providing an upper pivot point for the elevation cylinder.

Three additional lengths of angle iron are used for the support of the pivot frame and the lower support of the azimuth control cylinder.

Keep in mind that these dimensions are for a two-meter dish. A slightly larger dish could be accommodated, but if your dish is much larger, the A-frame will have to be made longer.

It would be well to mention a valuable construction hint at this time. Although it is theoretically possible to drill all the necessary holes accurately by being very exact in your measurements, in reality it is somewhat difficult. As you may have noticed in cutting-detail Figs. 1, 2, and 3, no measurements are given for hole placement. Ex-

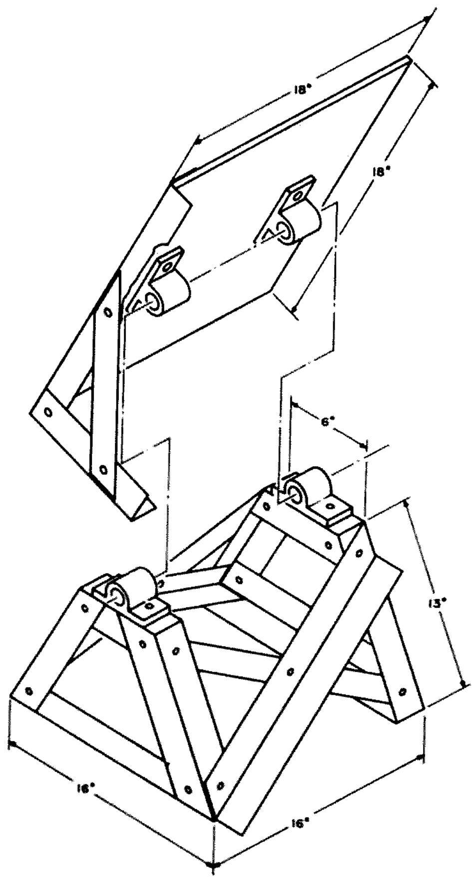

Fig. 3(a). Assembly detail for the pivot frame.

Parts List

Electrical controls

P1	110-V, 15-A ac plug with ground
F1	15-A fuse and holder
F2	5-A fuse and holder
T1	24-V, 5-A transformer
D1	5A, 50-V power diode
C1	1000-uF, 50-V dc electrolytic capacitor
I1-I5	24-V indicator lamps (may substitute LEDs with proper resistor)
TB1	3-position terminal barrier strip
TB2	10-position terminal barrier strip
RY1-RY5	24-V relays, SPDT type
S1	SPST power switch rated at 15 A or more
S2,S3	SPDT center-off toggle switch
S4-S7	Heavy duty microswitch (outdoor type)
PS1	Hydraulic-type pressure switch set to make at 300 psi
MI	Hydraulic pump drive motor

Hydraulic controls

Hydraulic pump capable of delivering 500 psi at .5 gallons per minute
4-way control valves, 2 each
Double-acting hydraulic cylinders, 1.5" bore, 18" stroke, 2 each
Needle valves (flow restrictors), 2 each
Hydraulic pressure regulator set at 500 psi
Oil reservoir tank, approx. 1 gallon capacity
Hydraulic accumulator (optional)

perience has shown us that the easiest way to drill these holes is to clamp all the pieces for a particular section together first. Then the holes can be drilled through the mating sections. This alignment of all the pieces and their holes will ensure accurate and easy assembly.

Pivot Frame

The pivot frame is mounted in the center of the A-frame and provides the azimuth axis and support for the dish.

The prototype shown in all the photos has the pivot frame constructed of three-quarter-inch pipe welded to form the frame. This is because the frame was built for another use but fit so well in this project that I just could not pass it up. My new design is just as good, however, and can be built without any welding. See Fig. 3. Two trapezoidal upright frames are constructed of 2″ × 2″ angle iron. A bronze bearing pillow block with a one-inch bore bolts to the upper short bar of each trapezoid. To prevent lateral movement of the upright frames, cross members of 2″ × 2″ angle are bolted between the frames. This sawhorse-shaped pivot frame mounts on the two center cross bars of the A-frame described earlier.

A length of 1″ steel shafting runs through the two pillow blocks atop the pivot frame and forms the azimuth axis.

At this point we are ready to mount the dish. If your dish has a center-type mount, you probably can use our system with no changes. However, if your dish has a different type of mount, some modifications may have to be made. We used an 18″ square of 3/8″ steel plate as a mounting surface for the dish. Two additional pillow blocks are bolted to this plate on the side opposite the dish. This plate is one half of the hinge formed between itself and the pivot frame.

The same "clamp and drill" method of construction used in the A-frame should be used for the pivot frame.

Steering

As mentioned earlier, all positioning of the antenna is done with hydraulic controls. This type of system was chosen because it provided accurate positioning ability and simplified mechanical design; most of all, however, a hydraulic system was the easiest to make weather resistant.

Azimuth steering is accomplished with a hydraulic cylinder attached between a piece of 3″ × 3″ angle iron on the main A-frame and a steering arm attached to one edge of the dish mounting plate. This steering arm is shown in a partially extended position in Photo B. The dimensions of the steering arm were selected so that the maximum amount of travel could be realized with the available hydraulic cylinder size. Both the azimuth and elevation cylinders were obtained from surplus sources. The length of the cylinder we selected combined with the pitch of the roof the antenna is mounted on gave us the necessary elevation angle for the antenna at our location.

Depending on your geographic location, you may need to change the length of the elevation cylinder or the vertical position of its mount to achieve your correct elevation angle. Positioning data for your location can be computed from the formulas given in Dr. Ralph E. Taggart's excellent article in *73 Magazine.*[4] The cylinders we used have a stroke length of 18″ and are double acting; that is, they can push or pull, depending on which end of the cylinder is receiving fluid pressure.

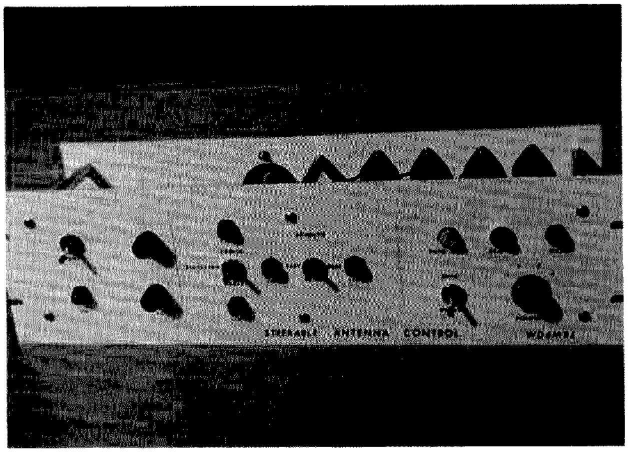

Photo C. Control panel for the steerable mount. Note that the controls on the right third of the panel are for the future installation of automatic positioning controls.

Hydraulic System

A half-horsepower electric motor is used to drive a small hydraulic pump that provides 500 psi of oil pressure. See Fig. 4. This type of pump as well as the cylinders and control valves can be purchased from sources such as those listed at the end of this article.[5,6] Pressure is controlled by a pressure regulator with all excess oil returned to the reservoir. Normally-open pressure switch PS1 (Fig. 5) closes at 300 psi and actuates relay RY1 allowing the control circuits to become active. The purpose of PS1 and RY1 is to ensure that hydraulic pressure is up before any operation can begin. More on this later.

Oil at 500 psi then flows through two flow-restrictor needle valves that control the velocity or rate of position change of the antenna. These needle valves must be adjusted for a flow that will allow accurate control of the dish position. The electric four-way valves are the hydraulic equivalent of

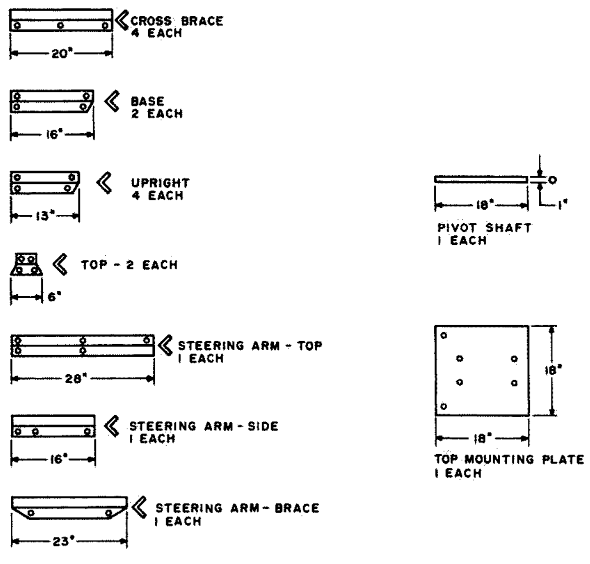

Fig. 3(b). Cutting detail for the pivot frame. All angle iron is 2″×2″× ¼″ and all holes are ½″.

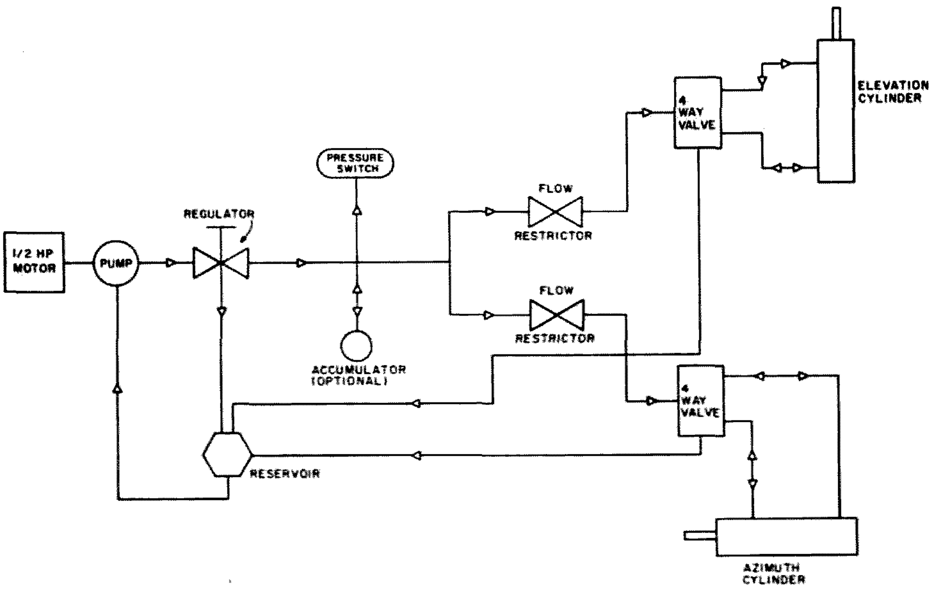

Fig. 4. Hydraulic system diagram. Due to the varying availability of surplus hydraulic components, your system may have to be somewhat different, but the same basic design should be followed.

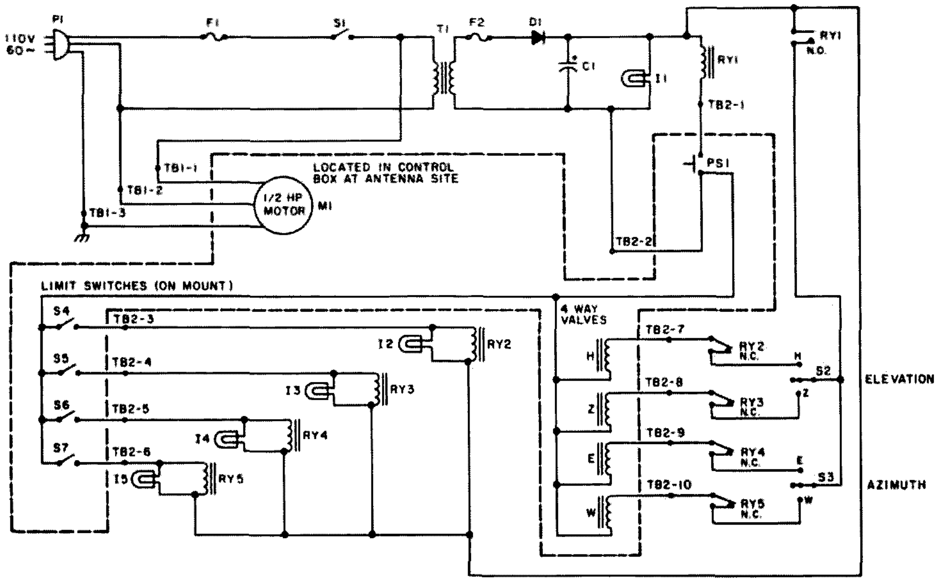

Fig. 5. Control panel wiring diagram.

a center-off SPDT switch. With no power applied to either coil, no fluid will flow to either side of the cylinder. With power applied to one coil, pressure will be applied through the valve to one side of the cylinder, thus moving the piston. Oil on the other side of the piston is returned through the valve to the reservoir. Conversely, if power is switched to the other coil, the piston will move in the opposite direction. An accumulator, a hydraulic cushion, can be installed as shown in Fig. 4 if the system "clangs" or shocks every time the four-way valves operate.

Control Panel

Currently, the electrical controls are only manual. Later, we plan to design a steering control that will input coordinates in degrees latitude and longitude and automatically position the antenna. For now, though, the circuit is simple and straightforward. Fig. 5 shows the circuit currently in use. Power is controlled by S1. Turning on S1 will start the hydraulic pump motor and apply power to the 24-V dc power supply. When hydraulic pressure is up to at least 300 psi, PS1 will close and actuate RY1 applying 24-V control to the position control switches, S2 and S3. These two switches are center-off SPDT type.

Transferring S2 to the horizon position will apply 24 V through RY2 NC to pick the four-way valve coil. This will apply motion to the antenna towards the horizon. If motion is attempted beyond the possible travel limits of the elevation cylinder, a limit switch will be closed. This switch is operated by a lever on the A-frame. Closing the limit switch will actuate RY2 thus opening RY2 NC. The four-way valve coil will drop out and cannot be re-energized until the overtravel condition is cleared. This same system applies to the other directions as well.

Summary

The development of this mount required several months of work before a design was arrived at that provided a well-balanced, sturdy, and easily reproduced device.

Actual construction time involved almost two months of weekend work, but has given us an antenna and mount with which we can enjoy many years of satellite signal reception.

We will be glad to answer any questions you may have about this project if you will please send an SASE. ■

The History of Ham Radio
—part XIV

Reprinted from QCC News, a publication of the Chicago Area Chapter of the QCWA.

Radio conferences, now commonly referred to as the Hoover Conferences, became yearly affairs and the assembly of 1925 was no exception. The conferences were called to bring about a degree of cooperation between various branches of the developing radio industry. Primarily to cope with the ever-increasing proliferation of interference problems in the interest of the listener and to mediate the differences between broadcast license applicants, government regulation became of paramount importance.

This, the fourth conference, was to be the last one called by the Secretary of Commerce. Radio's destination would be completely revolutionized in the subsequent two years by bringing about the needed legislation to replace the 1912 law.

Convening in Washington on November 9th, 1925, some 700 participants from all sections of the United States were present—and only for three days. They soon came to unanimous agreements on all major issues. The spirit in which various questions were approached signified common understanding of the direction which radio broadcasting was to take in the future.

By the end of 1925, there were some 600 radio broadcast stations operating in the United States with no enforceable regulations. The opinions of the conferees were practically unanimous in favor of not limiting the number of broadcasting licenses issued, but actually to diminish the stations on the air so that the radio listener would benefit from the reduced interference generated.

What was the radio amateur's position? At the conference, the question of greatest interest to amateurs concerned the retention of the 150- to 200-meter band. Its takeover was threatened by the broadcasters. However, after serious consideration, no additional channels were allocated for the broadcast service.

Several recommendations were promulgated for the amateurs:

1. The opening of a 100-kHz band from 83.3 to 85.7 meters (3500 to 3600 kHz) to amateur phone operation, the usual quiet hours applying.
2. The opening of the so-called amateur 80-meter band to naval aircraft.
3. The prohibition of spark to all waves below 200 meters.

These recommendations were to take effect after formal announcement by the Department of Commerce. Meanwhile, the regulations of the past year remained for amateur guidance.

Mr. Hoover, in his opening remarks at the conference, referred in particular to the progress radio had made during the few years of development.

"It has been suggested that the remedy [for congestion] lies in widening the broadcasting band, thus permitting more channels and making it possible to provide for more stations. The vast majority of receiving sets in the country will not cover a wider band. Nor could we extend it without invading the field assigned to the amateurs, of whom there are thousands and to whom constant experimentation in radio development is so greatly indebted. Radio in this branch has found a part in the fine development of the American boy, and I do not believe anyone will wish to minimize his part in American life. And if we did absorb the upper amateur band from 150 to 200 meters, it would not even solve the immediate difficulties . . ."

The conference went on record recommending the following:

1. That no new stations be licensed until, through discontinuance, the number of stations is reduced and until it shall be in the interest of public service to add new stations.
2. That public interest as represented by service to the listener as opposed to private desire be the basis for the broadcasting privilege.
3. That further division of time among stations is not in the interest of public service and that the Department decline to grant any more licenses until the present number of stations is substantially reduced.
4. That duplication of frequencies not be permitted in the case of stations of greater than 500 Watts of power.
5. That advertising efforts via the broadcast be confined to the providing of meritorious programs which build goodwill for the sponsor.
6. That in issuing licenses, the Department uses dis-

crimination looking toward the location of all broadcasting stations outside of congested centers.

7. That Congress be requested to enact new radio legislation vesting the administration of radio in the Secretary of Commerce, subject to approval of an appropriate court.

With the unanimous adoption of the many reports and resolutions at this conference, the radio industry at last came to the realization that a new law was a pressing necessity and new legislation must be prepared as the next big effort by Congressman White, and as was indicated by the report of Hoover's committee on legislation, could now receive unanimous affirmative consideration.

Fourteen Years of Haphazard Growth Come to an End

Without a change in radio legislation in 14 years, especially since the end of World War I, Herbert Hoover had been in control and guided the radio developments as Secretary of the Department of Commerce. These were chaotic years for radio. The radio amateur was in the forefront of practically all major progress made in radio, especially with the support and cooperation of the Commerce Department.

With radio neglected by Congressmen, and court cases looming on the horizon, Herbert Hoover was not only willing to drop out, but also was certainly justified in surrendering the control of radio guidance. Hoover was now willing to surrender further attempts at assigning wavelengths and regulating times of operation and power of stations. He was ready to renounce the absolute control of broadcasting. ■

The Skeptic's Multiband Ground Plane

—This antenna flies in the face of accepted theory. Do you think it will work?

The idea of feeding a vertical antenna—more specifically, a ground-plane antenna—with balanced transmission line is not new. Balanced, open-wire line lends itself well to multiband antenna applications because of its low loss in comparison with prefabricated coaxial lines. The transmission line used with the antenna described here is designed to have the least possible attenuation within reasonable limits.

How can balanced line possibly work well with an unbalanced antenna? Won't there be radiation from the line, and won't this cause horrible TVI and other problems? Well, since hams have been using unbalanced line (coaxial cable) to feed balanced antennas (dipoles and beams) for a long time and it has been shown that this is a perfectly satisfactory practice, one might be inclined to ask whether the situation should be any different the other way around. In the case of the antenna at W1GV/4, balanced line is being used with success to feed a ground-plane antenna.

Let's take a look at some of the theoretical considerations of balanced transmission lines and antennas before I describe a multiband ground-plane antenna without coils or traps that has proved very effective.

Parallel-Wire Line

In the old days of radio, the type of transmission line most often used was of the open-wire variety. The reason this kind of line works is that at every point along the line the currents in the two wires are always equal in magnitude and opposite in direction. Since the two wires are very close together with respect to the wavelength, they may be considered to occupy the same space. The field produced by one wire therefore cancels that produced by the other wire, and no radiation takes place.

For the currents in the two wires to be exactly equal and opposite, the antenna must have certain characteristics. If one side of the antenna presents a different impedance than the other, the currents in the two feedline wires will not be exactly equal or exactly out of phase. This may occur because one side of the antenna is longer than the other, or because one side of the antenna presents a different capacitance with respect to ground. See (a) and (b) in Fig. 6.

There is a third reason for radiation from a parallel-wire line: antenna currents. If one side of the antenna is closer to the line than the other side, the electromagnetic fields from the two halves of the antenna will not cancel each other in the vicinity of the line. This will induce a current in the line equal in magnitude in both wires but in the *same*

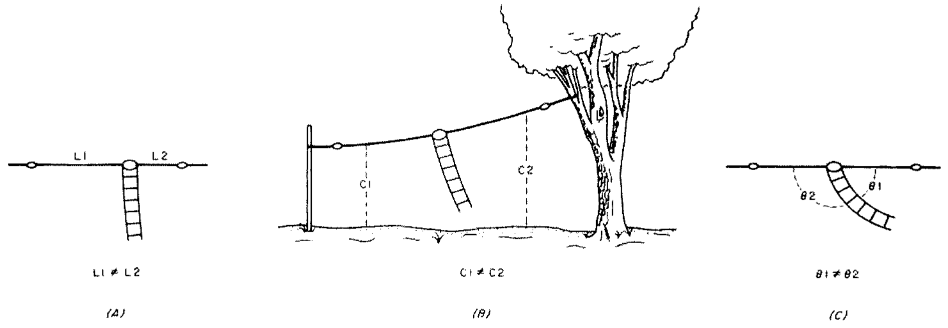

Fig. 1. Causes of feedline radiation. At A, antenna not fed at center; at B, one side of antenna closer to ground or obstructions; at C, feedline brought away from antenna in a non-symmetrical position. These factors can cause radiation from coaxial as well as parallel-wire lines. A perfectly balanced system is, fortunately, not usually necessary for satisfactory antenna performance.

direction (C in Fig. 1). Consequently, the line radiates because this current produces its own electromagnetic field. These antenna currents cause the net current flow in the two wires not to be equal and opposite, and this can result in trouble with an all-too-familiar gremlin for hams: rf in the shack!

Usually, a small amount of radiation from a transmission line is not a great handicap. This is fortunate because it is almost unavoidable. We certainly would want to minimize line radiation if we were using a highly directional antenna where front-to-back ratio is important. But with a simple antenna such as a dipole or ground plane, we need not worry about some deviation from theoretical perfection.

Coaxial Line

Many hams got it into their heads that coaxial line is shielded and therefore cannot radiate. This is not the case! Coaxial lines are just as susceptible to radiation-causing factors as parallel-wire lines. Antenna currents, induced in the outer conductor of coax, will produce electromagnetic fields and rf in the shack. These currents can be caused by any of the three situations shown in (a), (b), and (c) in Fig. 1.

Coaxial line has the advantage of being easy to install. It can be run close to or directly over metal objects such as gutters and pipes, and its attenuation characteristics and impedance will not be affected. This is not true with parallel-wire line. Metal objects very close to the latter type of line will cause "impedance bumps" and possible imbalance.

The main disadvantage of coaxial line is that it has relatively high attenuation. The swr becomes important at high frequencies or with long runs of line. Generally, the antenna must, impedance-wise, be fairly well matched to the line if coax is to be used with maximum success. Any time the swr is 2:1 or better, the line will function at essentially full efficiency. But an swr of, say, 20:1 will almost always cause significant signal loss. Furthermore, such a severe mismatch can cause conductor or dielectric breakdown because of extreme currents and voltages at nodes along the line.

A heavy-duty, balanced transmission line such as is used at W1GV/4 can be operated at amateur power levels with utter disregard for the swr. Thus, all the matching can be done conveniently at the operating position by means of a transmatch.

The Ground Plane

A full-size ground-plane antenna consists of a quarter-wave vertical radiator and several quarter-wave radials (usually three or four), and the base is at least a quarter wavelength above the ground. Such an antenna exhibits excellent low-angle radiation characteristics and consequently is good for DX work. It is less effective for local communication where the angle of radiation must usually be nearly 90 degrees with respect to the horizon. However, the low-angle reputation of vertical antennas has been somewhat overemphasized. Even at a radiation angle of 45 degrees the field strength is nearly as great as it is parallel to the horizon—see Fig. 2. The ground plane is an uncomplicated and versatile antenna.

As the base is lowered to heights of less than 1/4 wavelength above ground, losses begin to occur because the *ground currents,* which should be confined to the radial system, will begin to flow in the lossy earth. Three radials comprise a nearly perfect

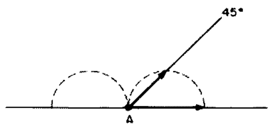

Fig. 2. Vertical-plane radiation pattern for a quarter-wave ground-plane antenna. Although it is generally thought that such an antenna radiates only at very low angles, we can see that it radiates quite a lot of energy at high angles. Only near the zenith is the radiation level very low.

ground if the base is sufficiently elevated. At a height of 1/8 wavelength, some of the ground currents will flow in the earth unless radials are added. The closer the base gets to the ground, the more radials are necessary.

Suppose we tune a full-size, 20-meter ground plane by means of loading coils so that its resonant frequency becomes 7 MHz. If the antenna was 1/4 wavelength above the ground on 20 meters, it will be 1/8 wavelength above the ground on 40 meters. The radial system will not be as good at the lower frequency because of the lower height. Also, the radials are not 1/4-wavelength long on 40. Although they are an *electrical* quarter wave in length, their *physical* length is just 1/8 wavelength. This fact, too, will cause more of the ground currents to flow in the soil. But suppose it is impractical to make the radials any longer; how are we to improve the efficiency without raising the antenna?

The answer is, of course, to add radials. More radials will be required if their physical length is 1/8 wavelength than would be necessary at the same height with 1/4-wavelength radials. I did not try to mathematically figure out how many radials I would need. I just decided, arbitrarily, that eight would be a good number.

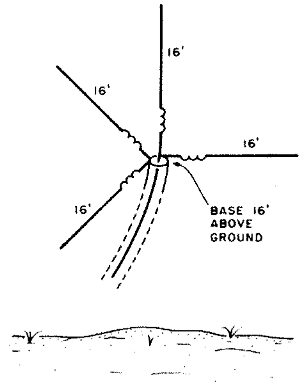

Fig. 3. Inductive loading of a 20-meter ground plane for use on 40 meters. Because of the lower electrical height and radial length, ground currents are no longer confined to the radial system. To restore a good image plane, we must either raise the antenna or add radials.

But maybe I'm getting ahead of myself. The loading system I used did not require any coil winding; this would have restricted me to 40 meters, anyhow. I wanted a 40-through-10 system without any traps or coils or stubs or multiple radiators. The mission was accomplished simply by feeding a 20-meter ground plane with open-wire line.

The Feed System

The actual installation is roughly illustrated in Fig. 4. The antenna acts as a full-size, quarter-wave ground plane on 20 meters. On 15 and 10 meters there is some gain at low radiation angles and correspondingly less radiation at higher angles. This works out very nicely since only low-angle radiation will be returned to Earth by the ionosphere on these bands; the skip distance is usually so long that high-angle radiation will pass through into space.

On 40 meters, the antenna is the equivalent of that shown in Fig. 3, except that there are eight radials rather than three. The radiation resistance at the feedpoint is very low on 40, so it is im-

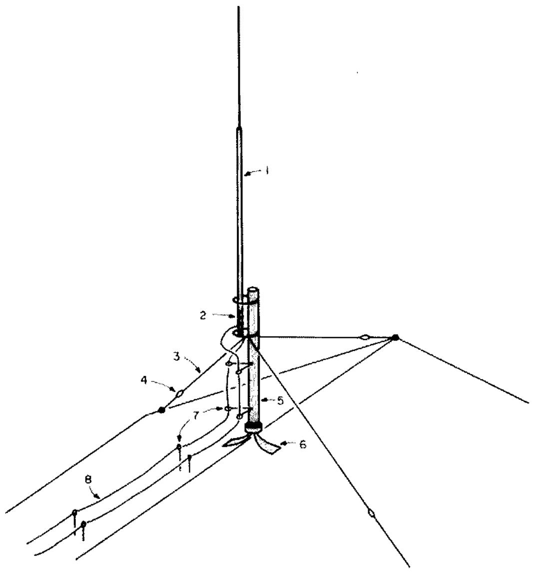

Fig. 4. The system at W1GV/4. Only three radials are shown, but there are actually eight. A feeder-wire spacing of 5 inches is maintained. (The viewing angle may give the impression that they are unevenly spaced.) Illustrated by number: 1—16-foot vertical radiator; 2—hose clamps attaching feeder to vertical radiator; 3—radial wire, 16 feet long, no. 8 solid aluminum ground wire; 4—strain insulator; 5—mast, 5 feet long; 6—TV base plate; 7—TV standoff insulator; 8—feeder wire, #8 solid aluminum ground wire.

portant that the connections between the feedline and the antenna be excellent. The feedline is constructed of #8 soft-drawn aluminum TV ground wire, which can be found in most hardware stores. The spacing used at W1GV/4 is five inches, but any spacing between three and six inches is satisfactory. Since the dielectric is air and the wire is very heavy, this line has just about the least attenuation possible. All connections are aluminum-to-aluminum, avoiding any corrosion problems that might result from contact between dissimilar metals. (Perhaps immersing the entire system in liquid helium would reduce the attenuation still further!)

The antenna itself is unbalanced; the current is different in the radial system than in the vertical radiator. This is true on all bands. Furthermore, the antenna is non-symmetrical with respect to the transmission line, and some feeder radiation is thus inevitable. It should be noted, though, that coaxial line also will suffer from the non-symmetry of the ground plane.

This non-immunity of coax to radiation-causing effects has already been discussed. How much difference, if any, is there in practice? This was determined by means of a field-strength meter. Originally the system was a coax-fed 20-meter monoband antenna. Tests were conducted at various locations in the vicinity of the feedline on 20 meters both before and after the changeover to balanced line. There is a little bit more radiation from the open wire, but the difference is hardly noticeable. Radiation levels in the shack are the same with both types of line (at the same power level, of course).

On 40 meters, the antenna is "tuned" by the feed system rather than by coils as in Fig. 3 (The 1/8-wavelength section of line closest to the antenna has replaced the inductors.) On 15 meters, the feedline also "tunes" the antenna. On 10 meters, the feedline has no actual tuning effect; the antenna is theoretically voltage-fed on this band.

We can be pretty sure that the swr is very high on all bands. But the line has such low attenuation that the swr is of no practical concern. We haven't even paid any attention to the characteristic impedance (Z_0) of the line! It is probably about 500 Ohms. Assuming the feedpoint impedance is 40 Ohms resistive on 20 meters, the swr is about 12:1 on this band. It is no doubt quite high on 15 and 40 meters also, because of the reactance at the feedpoint on these bands. On 10 meters, the feedpoint presents a pure resistance, but its value is difficult to predict. There is a possibility that the line is nearly flat on 10. But it doesn't really matter.

Construction Details

In order to minimize losses, every effort was made to ensure that there are no electrically "weak" points in this antenna system. The feedline spacing is five inches; long TV stand-off insulators are used to support each wire individually at 10-foot intervals. The wire is wrapped with electrical tape until it fits tightly in the large opening in the plastic part of the stand-off insulator. No splices should be made in the line; soft-drawn no. 8 aluminum wire is usually available in lengths that are any multiples of 50 feet.

The wires should be positioned so that they do not come within five or six inches of metal objects. If the wires must be run parallel and close to a metal pipe or downspout, both wires should be kept at the same distance from the object. If the feedline must cross over such an obstruction, it should cross at a right angle. These precautions minimize chances of imbalance.

The connections at the antenna are made in such a way that the primary electrical contact is aluminum-to-aluminum. One feeder wire is clamped directly onto the vertical radiator at the base, using three hose clamps spaced one inch apart. The other wire is connected to the aluminum base mount, using the nut on one side of the lower U-bolt holding the base mount to the mast. (The base mount at W1GV/4 comes from a 14AVQ that has been mutilated from experimentation.)

The eight radials, each 16-feet long, also are made of #8 aluminum ground wire. The radials double as guy wires; strain insulators are used to obtain the correct lengths for radial purposes. The mast is five feet tall. This, in additon to the height of the house, puts the base about 16 feet above the ground.

It should not be necessary to go into much more construction detail. The builder can put the antenna together to suit particular needs and passions. The radials should be the same length as the vertical radiator, but 16 feet is not a magic length. Actually, the longer the better. However, any length over about 18 feet will raise the radiation angle on 10 meters; lengths greater than 25 feet also will raise the radiation angle on 15 meters. This may or may not matter, depending on band preferences.

The length can also be less than 16 feet. However, as the length is shortened from this value, the radiation resistance will decrease markedly on 40 meters and will rapidly become so small that losses will occur no matter how

hard we try to prevent them. I can't tell you an exact minimum length because there is no real cutoff. You'll probably be able to make some contacts on 40 even if the length is four feet, but if you opt for this size antenna, you can rest assured that it will not be very efficient.

Performance

As of this writing, the antenna described here has been in use at W1GV/4 for about four weeks. Many contacts have been made, both long and short haul. Several thick DX pileups were cracked on the first or second attempt. Europe and Japan have been worked on 40 meters, where the antenna is half-size. Since it is a vertical antenna, we should expect that the low-angle radiation will be good even on 40 meters, so this is not too surprising.

The antenna seems to work exceptionally well on 10 meters; including the image, it acts as a vertical 2-element collinear on this band.

Mostly out of curiosity, I decided to try tuning the antenna on 80 meters and found that the transmatch did provide about 1.5:1 match at 3.5 MHz. The tuning was quite sharp, and I was indeed surprised to work a midwestern station and get a report of 589! Several other midwestern and northeastern stations have been worked on 80 with good reports. (Even so, I really can't believe that this antenna is very efficient at that frequency.) The antenna was designed with 40 through 10 in mind. Performance has been eminently satisfactory considering the unobtrusiveness, small expense, and simplicity of the open-wire-fed ground plane. ■

Dish It Out

— home-brewing a parabolic reflector, with the focus on cost

Some months ago, I began searching for a parabolic reflector to augment some gear for the reception of GOES weather satellite transmissions on 1691 MHz. A reflector on the order of 6 to 8 feet in diameter seemed like a good compromise, so the search went on . . . and on. After looking over some "finds" that several more fortunate hams had made, I began to realize that if you did locate a dish this size, you'd better have a fat wallet and a strong back.

Luckily, I happened upon an article by Norm Foot WA9HUV, in a May, 1975, issue of *Ham Radio* on open-grid parabolic reflectors.[1] This excellent article, along with some others (references 2, 3, and 4), and suggestions and formulae from Roy Cawthon who has had numerous articles in *73* regarding weather satellite pictures during the past several years, started me on this project. I'm grateful to both sources. You won't find any theory here—no proof of performance curves, etc. This is more in the nature of a nuts and bolts kind of article to encourage you along the same route. I can assure you that with a generous amount of diligence and average amount of dexterity (and little over $100 at this date), you'll have a good parabolic reflector. See Photo A.

Photo A. 8-ft. parabolic reflector. Elements are 5/8" aluminum tubing spaced 3". Reflective surface is reinforced with ¼" hardware cloth. The cylindrical horn is a 2-lb. coffee can with probe.

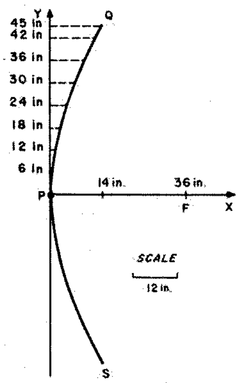

Fig. 1. Parabolic curve generated using $x = y^2/144$. Results are shown in Table 1.

A word about materials: This reflector is 2.3m (7½') in diameter. 8-foot lengths of 5/8" o.d. aluminum tubing (.049" wall thickness) were used. The tubing is the type found in hardware store do-it-yourself displays, a type that is easily bent and remains so after being bent. More rigid material, 5/8" electrical conduit, was used for the two main supporting members to which the elements are attached.

An F/D (focal length to diameter) ratio of 0.4 had been recommended as opti-

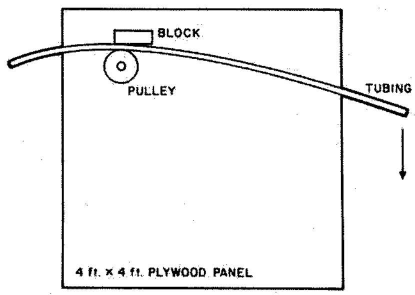

Fig. 2. Tube bending jig.

mum to facilitate illumination of the parabolic reflector. Following this, I chose a focal length of 36" and a diameter of 90". Element spacing is 3" on center (close to the 0.439 wave figure for 1-dB loss in Mr. Foot's data). To get at the business of element cutting (and use tubing cutters, by all means!), Fig. 1, Table 1, and the relations shown in the Math Box were used.

Element lengths, together with number required, are shown in Table 2.

Reflector Construction

A template will be needed to check bending and forming of the aluminum elements to fit the parabolic curve. Assigning 36 inches for focal length and solving $x = y^2/144$ produces the results shown in Fig. 1 and Table 1. Nails or screws at the x and y points will define the curve. The principal tool in the project is a tubing bending jig—that is homemade, too. I used a 4'×4' sheet of 1/2-inch plywood and mounted a 5-inch pulley and hardwood block according to the scheme shown in Fig. 2.

Mark the center of each of the elements. Slip the end in between the block and pulley, advancing the tubing in small bites and gentle bends. The pulley will aid in keeping the tubing parallel to the plywood surface. After just a few bends (even on the very first element), you'll get the feel of it.

I began with one of the longer (95") elements, fashioning it to the parabolic curve, then using it for a pattern for the remaining elements. After all the aluminum elements are formed, proceed to the two conduit supporting members. These will require a little more "tug," but you'll be a pro by that time.

The two supporting pieces (conduit) now are

Table 1. Curve coordinate dimensions (inches).

ready to be marked for drilling. An easy way to mark the center line is to make a scribe, using a wooden block and finishing nail. Drill a pilot hole in the block at half the tubing o.d., then insert the finishing nail. Place the conduit member on a level surface (the bending jig) and scribe the center line. Starting at the center of the conduit piece and working toward each end, mark off 3-inch intervals. Punch and drill these intersections with the center line, using a 7/64" bit. Drill through just the front wall. A 9/64" bit will be needed for the aluminum elements.

Number 6, 1-inch zinc chromate tapping screws (pan head) are used to fasten the aluminum elements to the conduit supports. Begin with the 32-inch end elements. Measure in 4 inches from each end of the 32-inch elements and using the 9/64" bit, drill through the elements. Attach the elements to the conduit supports, squaring up the assembly. From now on it's just a matter of centering each element on the frame, marking and drilling the elements, and attaching them with tapping screws. (A pair of sawhorses can be used to hold the frame, making the job easier on the back.) After all elements are in place, the conduit supports are prevented from sagging by inserting small "S" hooks in each end and connecting these with supporting lines of number 18 galvanized wire.

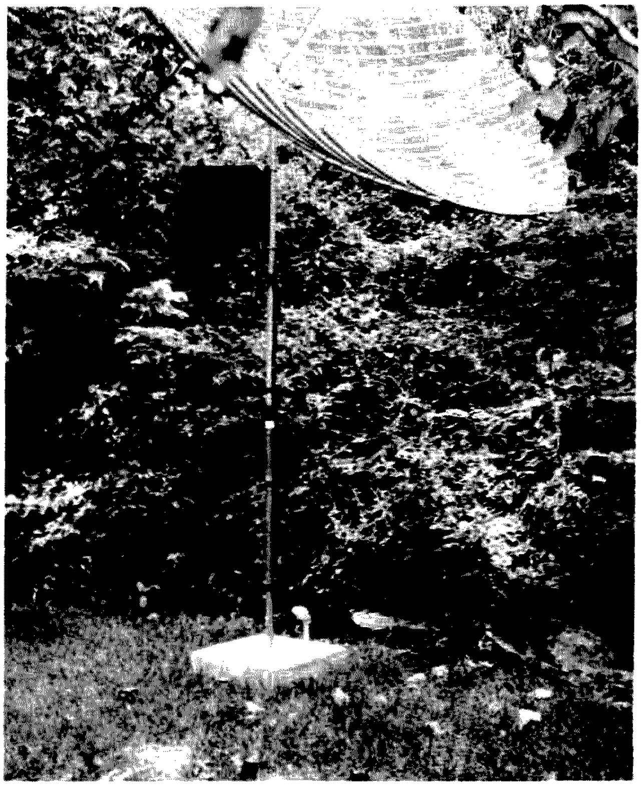

Photo B. Pedestal mount.

Boom Construction

A 26-inch length of 2×4 (treated with several coats of redwood preservative stain) is used for the top member of the boom. The assembled reflector is centered on the boom and attached with U-brackets and brass screws, using two brackets for each conduit support. See Fig. 3.

Install a 1-inch floor flange at the center of the boom to accept the cylin-

2 each (lengths rounded to nearest inch)

1 central section, extending to 96 inches, to be made of two 46-inch lengths installed on either side of a 1-inch floor flange centered on the boom. (27 lengths of tubing should do it.)

Table 2. Element lengths and number required.

Math Box

1) $r^2 = x^2 + y^2$—for sides and hypotenuse of right triangle.
2) $y^2 = 4Fx$—parabola at origin.
3) Arc QPS $= \sqrt{4x^2 + y^2} + \frac{y^2}{2x}(\log_e)\frac{2x + \sqrt{4x^2 + y^2}}{y}$ — length of arc of parabola.

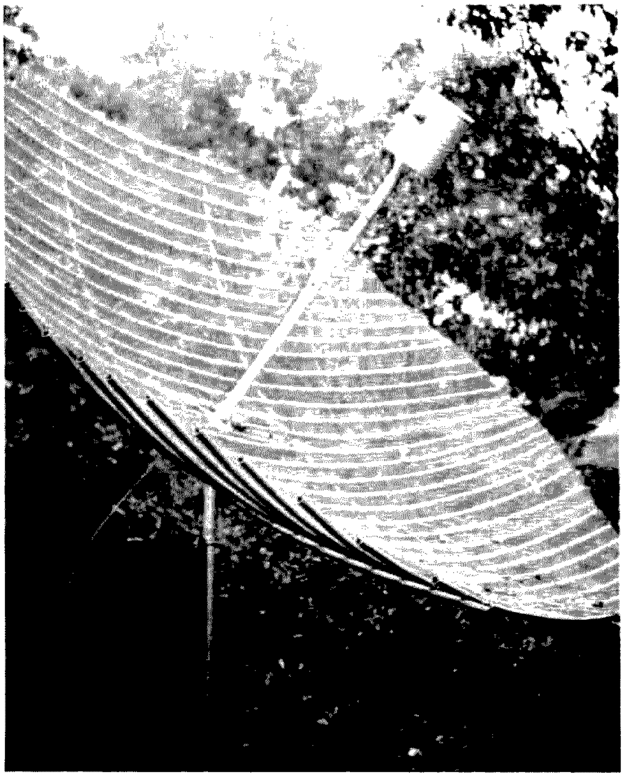

Photo C. Downconverter housing mounted on mast.

drical horn assembly. The horn support is made of 1-inch PVC (plastic) pipe. Cut a 24-inch piece of pipe and install a 1-inch male adapter at one end, using PVC cement. Cut a 12-inch length of 1-inch dowel rod, give it several coats of redwood stain, and install it in the open end of the PVC pipe section so that about 8 inches of dowel extends from the pipe. Attach this assembly to the floor flange.

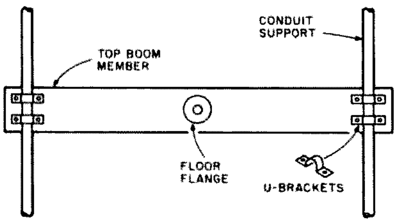

Fig. 3. Boom construction details.

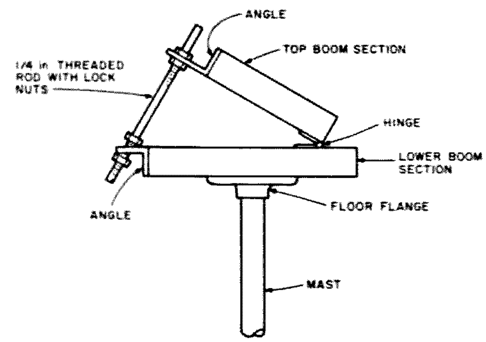

Fig. 4. Elevation adjustment details.

Elevation adjustment is provided by two pieces of 2-inch aluminum angle, 2 inches long, coupled by a 6-inch length of 1/4-inch threaded rod. See Figure 4. The lower boom section is a 26-inch length of 2 × 6 (treat with perservative stain). Another 1-inch floor flange is fastened to the bottom center of this member (use brass screws). The two boom sections are joined by 3-inch brass butt hinges. Attach the elevation control assembly as shown.

The completed parabolic (open-grid) reflector should weigh about 40 pounds. In order to thread it onto the mast, I inserted a 1/4-inch lag screw about 4 inches long into the center of the lower floor flange. This "pins" the assembly to the mast, making assembly a lot easier.

Pedestal

Posthole diggers were used to a depth of about 2 feet, then a form for the pedestal 18 inches square by 6 inches deep was constructed. A 10-foot length of 1-inch galvanized pipe, along with a section of 1-inch conduit (containing RG-8/U and 24 V ac lines) was set in the form. The block was poured, using several bags of ready mix. See Photo B.

Cylindrical Horn

The horn was constructed according to Taggart's article.[5] Using 3/8-inch Plexiglas™, a disk is cut to fit the open end of the 2-lb. coffee can (about 5.9 inches). Using an expansion bit, cut a hole in the center of the disk large enough to accept a 1-inch male PVC adapter. Cut a 1-inch PVC union into two parts. Install a 1-inch male adapter at one end of a 10-inch section of 1-inch PVC pipe. Insert this into the disk and snug it up with the piece of union just cut. Install the disk in the open end of the coffee can, drilling and tapping the Plexiglas disk for six 4-40 screws.

Downconverter Housing

A weatherproof box (11" × 12" × 15") of 1/2-inch outdoor plywood houses a MicroComm RX1691 downconverter. The box was treated with preservative stain and caulked with a generous amount of clear silicone seal. Actually, it's a box within a box, the converter being further enclosed by sections of 1-inch thick styrofoam. A regulated 12-volt dc supply shares the housing with the downconverter. See Photo C.

I used the open-grid reflector for several months, getting good results (usually full quieting) on the two GOES satellites I monitored: GOES Central and GOES East. Recently, I covered the reflector, installing sections of 1/4-inch hardware cloth (24-inch width) to the inside of the reflector with loops of number 18 galvanized wire; I'll admit that there has been some slight improvement in performance. I will certainly say that the open-grid performance was well within what one could expect from Mr. Foot's data.

The project looks much more formidable than it really is and the method easily could be extended to the fabrication of larger dishes, say, for TVRO satellite use.■

The Earth Mover

—would you believe that this antenna changes its height above ground without moving?

A few years back I was listening to a W8 station in West Virginia tell about how he put a reflector under his 80-meter dipole and his close-in signal improved so much that he sold his linear. He talked only with amateurs within a couple of hundred miles, and he was very pleased with the results. It greatly reduced interference, too.

Recently, I had an inverted vee 40-meter dipole at 60 feet which was very good into places like Australia and Europe, but which was not really good into the USA up to 1500 miles. Since I had a pair of phased verticals for DX use, I decided to lower the vee to 30 feet and found that it was much better into New Orleans and Florida but only fair into California.

I got to thinking about the West Virginia ham and also remembered that when I used to run Antarctic traffic with K1GZL he had tried what he called "a gadget," which was a reflector under his 20-meter driven element with three elements at 66 feet. We both had been talking to KC4VOS one night and he was shocked to get a report of S-6 when I was 20 over 9. Then he remembered that he still had his reflector up, and he ran out and lowered it. When he came back he also was 20 over 9 in the Russian Antarctic Station at Vostok.

His superb 20-meter, full-size, three-element wire beam thought it was only 20 feet above ground and became a high-angle radiator.

Now, what do you do if you have room for only one antenna and yet want to have both DX and local coverage? The answer is the old half-wave line trick.

A half-wavelength line will repeat the impedance at the load that is present at the source. Thus, if you short a half-wavelength line it will show a short at the opposite end.

Let's take an inverted vee as in Fig 1. The apex is at 60 feet, and this is a good height for DX. Actually, since a half-wave height would be 68′ 4″, that would be best for a low angle, but since your electrical ground may be anywhere from 3 to 10 feet below the surface, 60′ is good economical compromise.

Now let's place a reflector which is 5% longer than the driven element ¼-wavelength below it. This is about 34′. Fig. 2 shows the difference between the radiation angle at 60′ both with and without the reflector.

The length of the coax line should be ½-wavelength multiplied by the velocity factor of the coaxial line. This is .66 for polyethylene line. Thus, the length of a half-wave line at 7.2 MHz is 492/7.2 × .66, which is 45′ 1″. If this is not long enough to reach the transceiver, use twice that, or 90′. Forget about the inches since you probably won't be operating exactly at 7.2 MHz most of the time.

Now, at the station end, install a SPST switch, perhaps a toggle, with which to short the line.

Remember that we are talking about a separate line to the reflector and *not* the feedline from the transmitter to the driven element. (See line A in Fig.1; the feedline to the transmitter is at B.)

When you throw the switch closed, the reflector is in operation. When you open the switch, the reflector splits into two 20-meter lengths and has no effect on the antenna at 40 meters. Thus, you have a high-low antenna. Open switch—low angle; closed switch—high angle.

Be sure to run the coax down the tower at right angles to the reflector and

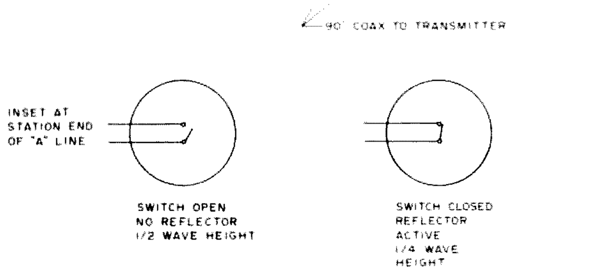

Fig. 1.

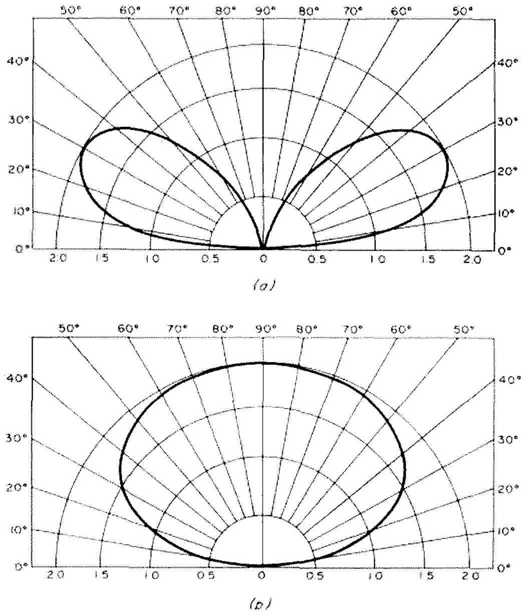

Fig. 2. (a) The radiation pattern with the reflector ¼-wavelength below the dipole. (b) The pattern of a dipole ½-wavelength above the ground without reflector.

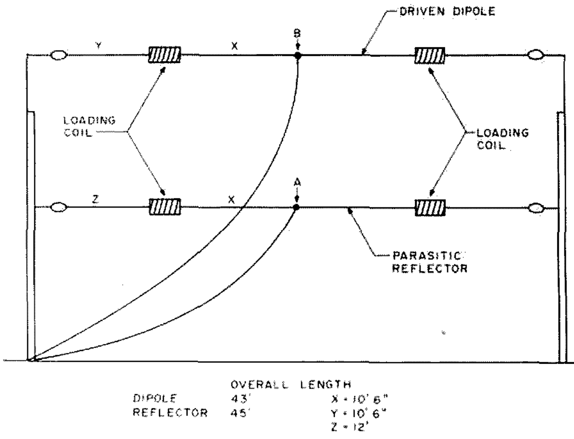

Fig. 3. All loading coils are identical.

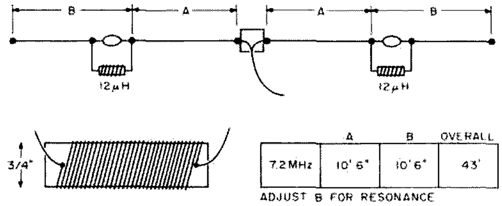

Fig. 4. Loading coil construction details. Inductance required is 12 uH. Close-wind 52 turns of #16 enameled wire on a ¾"-diameter plastic form. Windings should be 2¾" long. Hang coil across insulator at distance A from center of antenna as shown.

antenna to keep them out of the field as much as possible. Running them down inside the tower is the best way.

At this spacing there will be little or no change in the swr since the elements are a quarter-wave apart, and at that distance reflectors have little effect on the impedance of an antenna.

By the way, you can use RG-58 or RG-59 for the switching line to the reflector as there will be little power in the line. When the line is shorted it will take no power, and when the line is open it is detuned and still will take no power worth mentioning. As a matter of fact, you can use even twin-lead as long as you allow for the correct velocity factor of .82 and have a half-wave multiple.

This same principle will work for a flat-top dipole, of course, and will work fine on 75 meters if you have the space and that is your band.

If you are short of space and have two supports, you might try the method shown in Fig. 3. I have two towers 48 feet apart, and this is not room enough for 40-meter dipoles. I want to put up a low pair of 40-meter dipoles using a set of four traps which Bill Pace of Pace-Traps designed for me. Then I will put an 80-meter vee on the tower where the 40-meter vee is now.

Pace-Traps will build a set of coils for you for whatever space you have available. Write them at Box 234, Middlebury CN 06762. They do beautiful work, but if you want to wind your own the information is in Fig. 4, for 40 meters. Be sure to weatherproof them so that snow or rain will not change the inductance. (Pace-Traps are completely enclosed and do not need the external insulator shown in Fig. 4.) They have now added this coil series to their line of traps, for shortened dipoles. My two sets are for 40 meters, 43 feet, and 80 meters, 63 feet.

I expect to have good signals out to about 1000 miles with the 40-meter dipole at 35 feet, and a strong signal out to about 500 miles with the reflector working. This will keep out distant interference when I am working in nearby states, as I do in the daytime.

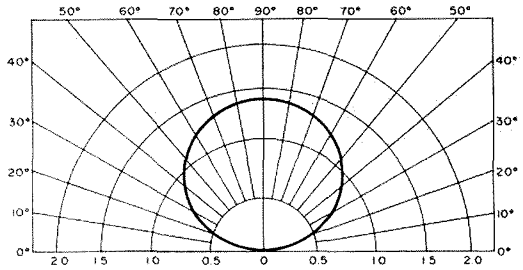

Fig. 5. The radiation pattern with the reflector 1/8-wavelength below the dipole.

The reflector will be 17′ below the driven dipole—1/8 wave. Even at higher dipole heights the reflector can be 17′ below it for even higher angle radiation. Fig. 5 shows the expected radiation pattern.

Some amateurs find that two to five reflectors about one or two feet above the ground below the antenna make a good substitute for a poor ground condition. This would be especially good if you are a local rag chewer on 75 meters. You will not need high power, and will get less QRM for emergency work.

High antennas aren't the answer to all problems. One large manufacturer of commercial equipment says that this is a common mistake of his customers—the use of high antennas for short distance work, such as close-in ship-to-shore operation. ■

Sailing the Triband Sloper

—put some half-waves among your halyards, matey!

Dennis Larson W8KXW
4551 Eastwood Dr.
Okemos MI 48864

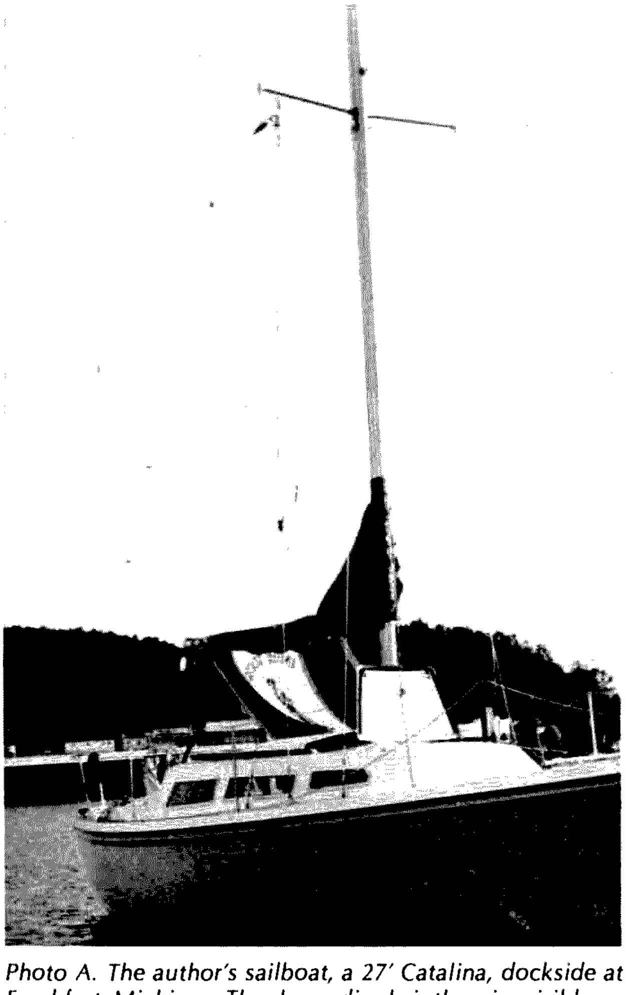

Photo A. The author's sailboat, a 27' Catalina, dockside at Frankfort, Michigan. The sloper dipole is the wire visible on the extreme left side of the picture. The two toggle switches on the lower end of the antenna and the coax feedline are clearly seen. Other wires constitute the rigging of the boat and support the aluminum mast.

Every antenna is designed within a particular set of parameters. I was limited by some specific and inflexible guidelines.

I needed an antenna that was absolutely portable. It had to work on the three most popular DX bands. Finally, its length could not exceed 36 feet.

The antenna was to be primarily used aboard my 27-foot sailboat. It would spend the winter as a backup antenna at my home QTH but had to be small enough to accompany me, my wife, and a TS-120S transceiver on a winter sailing vacation in the Caribbean.

Since 36 feet seemed very short, I did not consider a longwire antenna. But a half-wave dipole for 20 meters would be approximately 32 feet long. When coiled, such an antenna can be easily stored even with its coax lead attached.

There is only one convenient attachment point with any height on a sailboat—the mast. That made the sloping dipole particularly attractive since only one end had to be raised. The sloping dipole also promised a small gain in signal strength compared to a loaded vertical or short longwire; the criteria favored experimenting with a portable sloper. I wanted to be able to use the antenna on 15 and 10 meters as well as 20. Traps were out of the question because of their bulk. I also wanted to keep the cost of the antenna down.

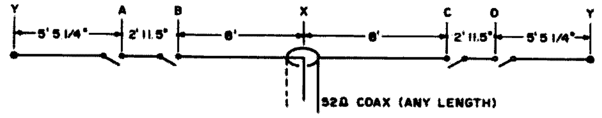

Fig. 1. Sloping dipole for 10, 15, and 20 meters. Using length = 468/f(MHz), total lengths were 16' for 29 MHz, 21' 11" for 21.3 MHz, and 33' 9½" for 14.25 MHz. A, B, C, D are SPST toggle switches. X is a center insulator or balun and Y are end insulators.

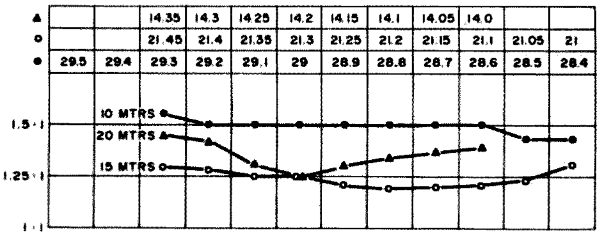

Fig. 2. Swr curves for triband sloper.

Multiband wire antenna designs I had seen described in various books suggested using insulators in the dipole at the required locations and adding clip leads to short across the insulators. In those designs, it is necessary to clip or unclip shorting leads to resonate the antenna on particular frequencies.

I didn't like the idea of using seven insulators; I liked clip leads even less. Since the antenna was to be used in a marine environment, I could predict that rigging or a sail rubbing against any clip leads would either cause the clips to work loose, chafe the sails, or both.

I was still looking for solutions when I wandered through a local Radio Shack store. I browsed through the varieties of toggle and knife switches. A knife switch could work both as an insulator to hold the antenna parts together and as a mechanism to electrically lengthen or shorten the antenna.

But an even smaller, lighter switching arrangement is available if the antenna is built using four toggle switches. The Radio Shack SPST toggle switch (#275-701) features a plastic body and wide brass contacts. I bought four, along with a package of insulators (#270-1518), and started building the sloper that night.

Fig. 1 shows the dimensions I used to build an antenna which resonates in the low end of the DX phone bands. The formula 468/f(MHz) was used to determine the lengths of three dipoles.

Starting with an old ceramic insulator from the junk box and some #14 stranded wire, I cut a 10-meter dipole to length, 8 feet on each side of the insulator. Those who advocate using baluns may find it more convenient to use one in place of the center insulator. Toggle switches were soldered to the ends of the antenna. I calculated the length of a 15-meter dipole, divided by two, and added the second length of wire (another 2' 11.5") to the first set of toggles. A second set of toggle switches was then soldered to the ends of the dipole and the final length of wire added to resonate the antenna on 20 meters (5' 5¼"). Dimensions given are finished dimensions and do not include the additional inches of wire wrapped onto toggles or insulators.

Attach the feedline to the center insulator. I used RG-58/U and I learned, through experience, that there must be strain relief for the coax. Since I reattached my feedline by passing it around the insulator and taping it to itself before soldering, I have had no further trouble. The antenna will *not* load if either side of the coax breaks! In the past, I have used 72-Ohm twinlead for feedline and I am sure that that would work well on this antenna. It would be even lighter than the coax, of course.

The Radio Shack toggles have brass contacts which I bent at 90 degrees to the switch body. There is probably not enough tension to distort them in an antenna this short, but it seemed more aesthetic to keep the contacts in line with the antenna.

Using a VOM, I determined whether the toggles were opened or closed. The Radio Shack switch is large enough to allow space for a label on the side of the toggle body. In the open position, toggles B and C (Fig. 1) act as insulators and the antenna becomes a simple 10-meter dipole. After identifying the open position, I used a soldering pencil to write "10" on the side of the plastic switch housing op-

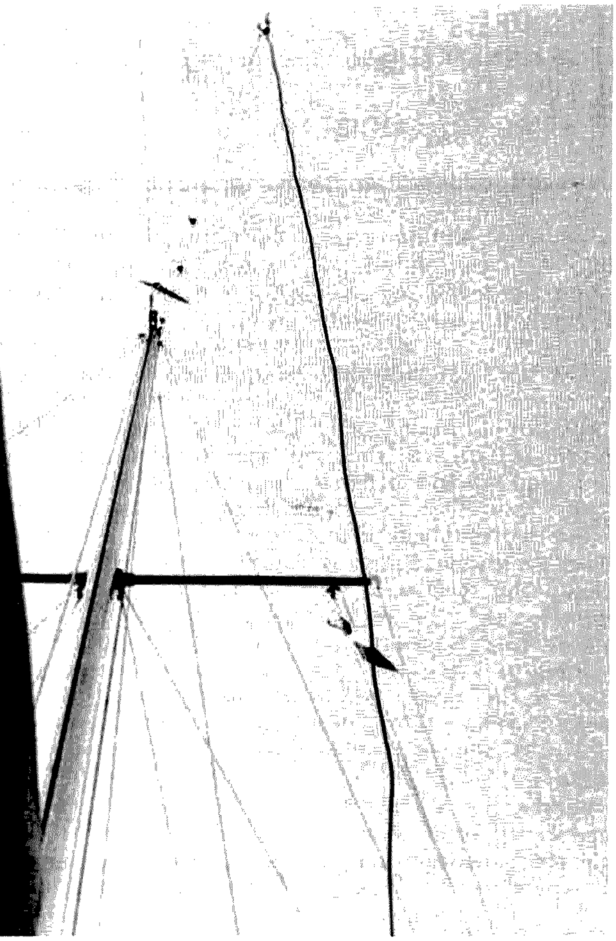

Photo. B. Looking directly overhead from the cockpit of the sailboat, the top half of the antenna from the center insulator to the mast is visible. Two toggle switches can be seen. Other wires are rigging.

posite that position of the toggle. In the closed position, the toggle indicates 15 meters. There I wrote "15".

Use the same procedure to identify the open and closed positions of toggles A and D. Open is labeled "15" and closed is labeled "20".

When operating from my boat, the antenna slopes between the masthead and the stern rail. The angle is steeper than 45 degrees and sometimes I describe the antenna as a vertical dipole. The slope is probably about 30 degrees from the mast.

During fair weather it is possible to leave the antenna erected while sailing. However, when I sail I usually untie the lower end and secure the antenna parallel to the shroud which supports the mast. Most of my operating occurs when at anchor or at dockside. Since I carry the Hustler system, I am still able to put out a signal underway if I want to.

The antenna is quite broadbanded, and in operating from the home QTH it loads without an antenna tuner. On the sailboat, the proximity of rigging and the aluminum mast affects the swr and an inexpensive tuner helps bring the antenna back to resonance. The rigging seems to have no noticeable adverse effect on the radiation pattern.

Fig. 2 is a graph of my swr calculations, computed while the antenna was attached to the 45-foot level of my tower in Okemos, Michigan.

Bandswitching is not instantaneous, as on a trap triband beam or trap vertical. But on my sailboat, I am only a few steps away from the halyard at the mast and I can lower, reset the switches, raise the antenna, and be back at my operating position on another band in less than two minutes. It is not as convenient to walk into the backyard to change bands when the antenna is in use at home but halyards on the tower make it as easy, if not as quick.

Okay, you say, simple to make—but does it work? It works beautifully. Obviously, it is not a beam, but transmitted signals seem to be stronger in the direction of the slope—as they should be. In other directions such as 90 degrees to the slope, it acts like a simple dipole, as near as I can determine.

I had dozens of satisfying rag-chews with stateside stations on the three DX bands during the summer of 1980. I easily worked into Europe and the Caribbean from Lake Michigan while running only 80-100 Watts output with the TS-120S. Signal reports confirmed the sloper worked better than the Hustler vertical mobile whips.

The sloper does not need the ground or counterpoise that is required of a vertical. My vertical, although grounded to the keel of the sailboat and with a pair of radials attached, would probably perform much better in salt water than it does on my sailboat in the Great Lakes. I have talked with sailor/hams operating in the ocean who report that the Hustler whips make fine seagoing antennas.

The sloper dipole went with me on a sailing vacation/casual DXpedition to Tortola in the British Virgin Islands in early December, 1980. If you talked to me as W8KXW/VP2V, you heard the TS-120S operating into the sloper dipole from aboard the 37-foot sailboat we chartered.■

Touch-Tune

—tactile frequency determination for visually-handicapped hams

A local ham with a visual handicap and limited wrist action needed a means to determine the frequency to which his Drake TR4-CW was tuned. The limitations of his license naturally determine the band limits within which he must operate. And he must do this with a very high degree of precision—to be able to go back to some designated frequency as well as to stay within the limits.

This article covers the approach taken for this amateur to modify his TR4-CW (it can be returned to normal with little or no problem) so that he could operate with relative ease and be sure of his frequency within ±1 kHz at all times.

The first method tried was to use label tape (Dymo™ or equivalent) with braille markings attached to the face of the transceiver front panel, using the dimple on the tuning-knob skirt as a reference point. This method lacked precision of adjustment and was difficult to use because of the limited wrist action of the ham. The markings can be seen under the new plastic disk in Photo A.

After studying the design of the tuning assembly on the transceiver in detail, it was apparent that the easiest and most practical form of frequency display would be a disk behind the tuning knob, in place of the graduated skirt. If the braille markings were on the peripheral edge of the skirt and the skirt were transparent, then either a sightless or a sighted amateur could operate the equipment. In addition, the limited wrist action would not be a problem.

A scrap of ¼"-thick plastic, such as Plexiglas™, was obtained from a local supply house at a very low cost. A local machinist turned a 3½" disc from this piece and drilled a ¼" hole in the center to fit the tuning shaft. See Photo C. A concentric hole had to be drilled partway through the disc at the center to allow for the larger diameter of the concentric shaft on the tuning shaft. This concentric shaft turns the plastic discs on the interior frequency display.

Drake has used a short piece of rubber tubing to transmit the turning motion of the knob to the interior frequency display discs.

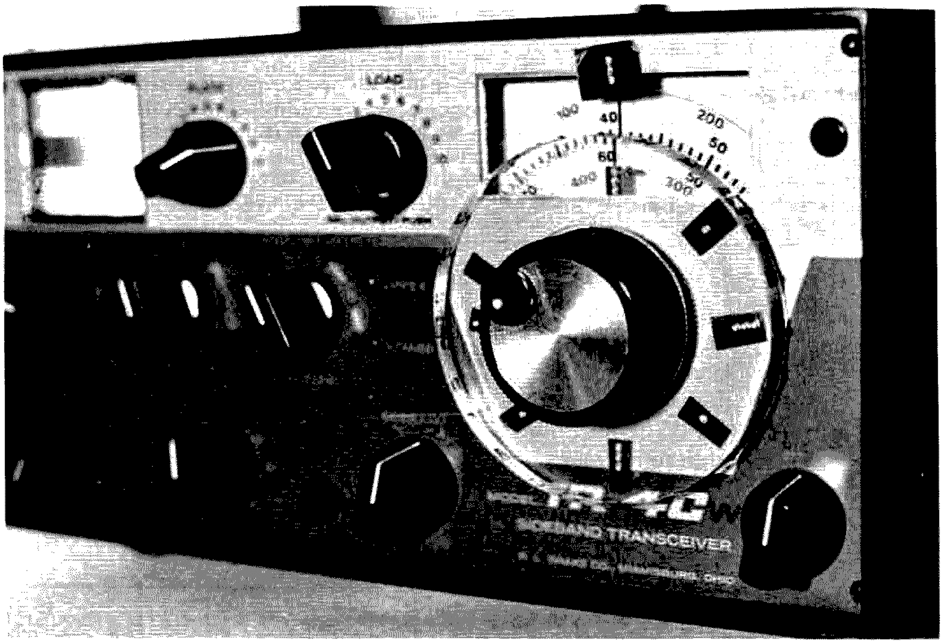

Photo A. Overall view of the TR4-CW with modification in place.

Photo B. Close-up of plastic disk and rubber spacer mounted on the tuning shaft.

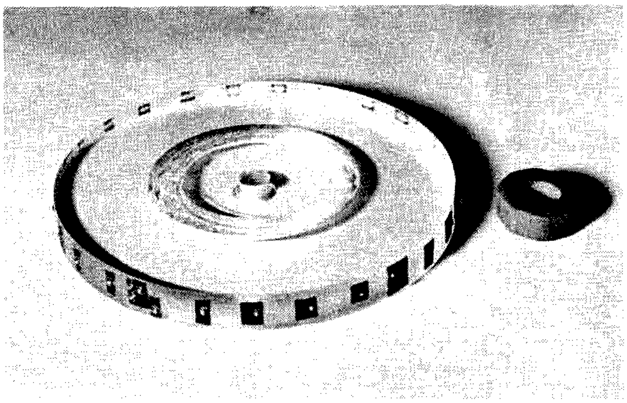

Photo C. Detail of plastic disk and rubber spacer.

Since our design for this modification precluded changes which would prevent returning the set to normal for possible later resale, a piece of ruby-red eraser was used to make a new pad that was not as thick as the original piece of tubing (see Photo C).

When the new parts, rubber pad, and plastic disc were assembled on the tuning shaft, it was discovered that the tuning-knob set screw would not engage the tuning shaft. This minor problem was overcome by machining a 3/16″ × 1/8″ circular flat-bottom groove. This groove allowed the knob to be inset into the new plastic disk far enough for the set screw to engage the shaft and its rough bottom to increase the friction between the knob and the new plastic disc. This machining must be done very slowly, or the plastic will chip along the edges or melt under the cutter. The original aluminum knob skirt was saved, along with the rubber coupling, so that the transceiver could be returned to normal configuration at a later date, if necessary.

Now that the mechanism was working, some method had to be derived so that frequency could easily be determined. Since the tuning system was designed so that one complete turn of the knob was 25 kHz, the perimeter of the new disk was divided at 25 equidistant points (perimeter divided by 25), representing 1 kHz per division. The braille system was used to mark the divisions. The dots were put on label tape, using a braille typewriter that the sightless ham owned. These small pieces of tape were then attached to the periphery of the disk at the appropriate places.

The 1-kHz points were simply marked with a dot while the 5-, 10-, 15-, 20-, and 25-kHz divisions were marked with the appropriate braille symbol and the left-most column of dots aligned as the marker. The starting and ending points were the same and were indicated with the 25-kHz braille tape. In order to establish a reference mark on the transceiver face, a simple column of dots was put on a piece of label tape and attached above the window of the face plate (see Photo A).

Since Drake does not specify the amount of overtravel of the PTO, each transceiver dial will stop at a different frequency. By determining the frequency of the stop (by a sighted ham) and counting the number of turns necessary to get to the edge of the subband, the amateur was able to establish one edge of the subband limit. The set screw hole in the knob can be set so that it is vertical when the edge of the subband is reached, thereby giving the amateur an additional point of reference for counting the number of turns from the PTO stop. The primary reference line is the left-hand edge of dots on the braille 25-kHz mark. With the subband located, the amateur now can stay within the band or operate on a predetermined frequency by aligning the dots used as reference on the front panel with the braille markings on the periphery of the disk. Using this method, the amateur can dial the desired frequency with an error of less than 1 kHz.

The system has now been in use for several months and is working very satisfactorily. The braille dots on the tape attached to the disk edge seem to stay much better than expected. In applying these markers, it is extremely important that the edge of the disk be absolutely clean and that the adhesive on the tapes not be touched with your fingers during application. Small pin heads could be used in the future, but they must be very small so that the ham can feel the entire braille digit without having to hunt around for it.

This scheme could be used on any equipment that uses an external tuning knob with enough shaft so that the knob can be reinstalled after the disk is installed behind it. Also, the frequency-tuning knob frequency-per-revolution must be something that is easily determined.

I would like to thank Jim Devilbiss WA3FUJ for machining the plastic, Bob Hurwitz K3DLC for the photographs, Joe Fincutter W3IK for his help in preparing this article, and Harry Mossberg WB3LFD for the opportunity to devise the system. ■

coil taps should cover progressively more turns, such as 3, 7, 15, etc., to utilize the full 12-position capacity of the coil-tap switch. Going up towards the kW level, one could use a 350-pF capacitor spaced for several thousand volts (E. F. Johnson 154-10) and 3"-diameter coil stock having 4-6 turns/inch to make up the inductance.

A problem at this power level, however, becomes that of finding a suitable coil-tap switch since, especially if low impedances are being matched, considerable amperage will flow through the switch contacts. It might be just as economical to use a roller inductor at the kW level. One suitable type would be the E. F. Johnson #229-203, 28-μH inductor, although various other surplus units which are available on the market also are usable as long as they have 18-28 μH of inductance.

The simple L-tuner is meant for use with an external swr bridge. However, one could combine it with the home-brew swr circuit described for the next tuner if one wanted a completely self-contained unit. Also, it should be noted that the normal/reverse switch arrangement shown could easily be expanded into an antenna-selector switch if desired.

The tuner diagrammed in Fig. 2 is dubbed the "six-square" tuner because it fits into a 6-inch-square aluminum utility box. It will match a far wider range of impedances than the simple L-tuner and, as shown, will handle 500 to 600 Watts PEP of transmitter output. It has been used with multiband antennas, loops, and random-length longwires with equally good results.

The circuitry used is that of a pi-network except that an extra series-capacitor arm has been added on the output side. The added capacitor allows a better matching range and also does not make the coil-tap points so critical. A commercial version of this circuit uses fixed, switched capacitors in place of the variable capacitor to ground on the antenna side of the circuit. One could experiment with this idea if one wants to save a variable capacitor by using five or six fixed capacitors to cover the range approximately from 50 to 300 pF.

Although a coil-tap switch is used, the coil taps are made adjustable by implementing them via spring clips rather than by soldering tap leads to the coil. This method requires a bit more work, locating a source for the spring clips (surplus ones were used), but the advantage is that one can experimentally determine the best coil-tap position for each band and then leave the taps set until an antenna is changed. Since the top cover of the tuner can be removed easily to access the coil, the whole arrangement becomes quite practical and costs far less than using a roller inductor.

As dimensioned, the tuner is mainly useful for the 10/15/20-meter bands. It can be dimensioned easily for the lower frequency bands by using coil stock with a turns/inch dimension which produces up to 28 μH inductance (e.g., 3"-diameter stock, 6 turns/inch, 5 inches long). However, on the lower frequency bands, the 300-pF variable capacitor to ground on the output side will usually not have enough range. One usually will have to parallel fixed capacitors to it so that a total capacitance of 1200-1500 pF can be achieved. The extension of the tuner to the kW level would not require changing the coil but the usage of a suitable

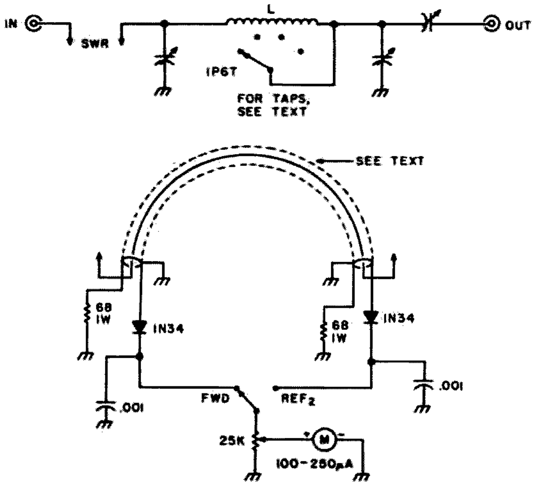

Fig. 2. Circuitry of the "six-square" tuner. The simple swr bridge which is built around a piece of RG-58 can also be used with any of the other tuners described. L is 2½" diameter, 4 turns/inch, 4" long. Capacitors are 300-pF, 2-kV surplus type.

coil-tap switch and wider-spaced variable capacitors as suggested for the circuit of Fig. 1.

The swr circuit used in the tuner is just about the simplest one that can be home-brewed, yet it is very effective. To construct it, one first strips the vinyl jacket off approximately 5½ inches of RG-58. The braid is bunched slightly and slipped off. Two lengths of enameled wire of any small gauge (e.g., #22) are then placed over the insulated center conductor and the braid replaced over the assembly. A 4½" length of shrink tubing is then placed over the braid and heated. The result is a 4½"-long pickup section with ½" left on each end for connections. The assembly can be bent into a U-form, and all the components for the swr circuit (except the sensitivity potentiometer and forward/reverse switch), can be mounted on a multiple-lug terminal strip.

The circuit will operate well over the 80-to-10-meter range with transmitter output powers of 25 Watts to 800 Watts. The meter used was a CB surplus one which happened

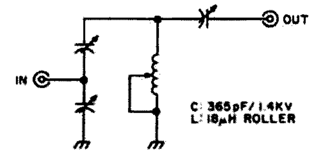

Fig. 3. A T-network type of tuner popularly called a transmatch.

to have an swr scale. Normally there is no need to use a meter with a calibrated scale since usually one will simply be adjusting the tuner for minimum swr in the "reflected" position with the sensitivity potentiometer set at maximum.

There is no special construction care required in putting together the six-square tuner. To provide easy coil access, however, the capacitors were mounted on the bottom cover of the utility box. The one capacitor which has to be above ground was mounted on a suitable piece of Bakelite and, of course, an insulated shaft coupling was used. It was centered between the two other capacitors so that its control shaft could pass between them to the front panel. There is still sufficient room in the enclosure to add an anten-

na-selector switch or 100-Watt-class, dummy-load resistor, if desired.

The final tuner unit is diagrammed in Fig. 3. Most amateurs have come to regard this type of tuner circuitry (which is a variation of a T-network) as the best of the "match anything" variety. Of course, it will not "match anything" any more than any other single-circuit configuration will do, but it does seem to have a wide enough matching range to satisfy most needs ranging from Field Day random wires to the usual fixed-station antennas.

A particular advantage of the circuit is that it does not require unusually large values of capacitance even on the low frequency bands. With the values shown in Fig. 3, the tuner will cover 80-10 meters. By changing only the roller inductor to a 28-μH unit, its range will be extended to 160 meters. With the components listed, the tuner will easily handle 300 to 500 Watts output. It can be made into a kW-level tuner just by substituting variable capacitors with wider plate spacing (e.g., E. F. Johnson 154-10 or equivalent with .075-inch or more plate spacing). The roller-inductor type does not have to be changed.

The unit is constructed in an LMB enclosure, #CR-864, which measures 8″ × 6″ × 4½″ inches. The variable capacitors are all mounted on a Bakelite panel placed in the middle of the enclosure. The panel is fastened to the rear and bottom of the enclosure by means of 4-40 hardware using holes drilled and tapped into the panel where it butts against the enclosure.

Two of the variable capacitors are joined by a shaft coupler to make up the dual-variable capacitor shown in Fig. 3. It is not absolutely necessary, however, to use a dual variable if one doesn't mind having an extra control to tune when two separate variable capacitors are used. A standard J. W. Miller turns counter is used with the roller inductor, but anything that one can improvise that will give the approximate location of the contact roller on the coil will suffice. It is hardly necessary to have a turns indicator that reads out to 3 digits! The antenna-selector switch and indicator LEDs on the front panel were intended for later use to remotely switch antennas by passing a dc voltage of different polarity down a coaxial transmission to control remotely-located relays. The basic scheme is shown in Fig. 4.

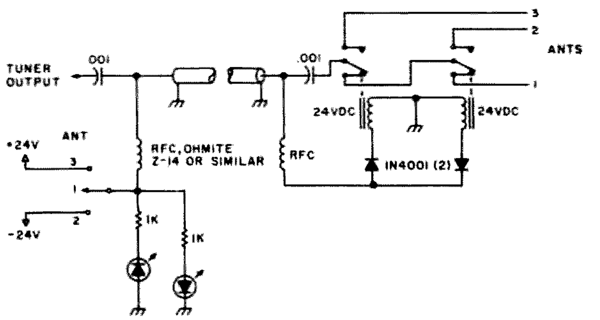

Fig. 4. The antenna-select switch shown with the last tuner was meant to implement a remote relay-switched antenna-selector scheme of the type shown here. Many good surplus 24-volt relays are available which could be used.

Each tuner can be expanded as desired and provisions made to work into a balanced transmission line by adding a balun. The #5 balun kit from Amidon will suffice for power levels of a few hundred Watts, and it comes complete with instructions on how to put together either a standard 1:1 or 1:4 balun. For a kW-level balun, one can follow the same basic instructions but use two or three Amidon T-200-2 cores stacked and covered with some form of good insulating tape, preferably a glass-cloth type.

The tuners are all used in a conventional manner. That is, tuning them so the swr on a coaxial line between a transceiver and the tuner is as close to 1:1 as possible. A general rule of thumb is to use settings on the tuners on each band so that the maximum capacitance is engaged. Some of the tuner circuits, particularly that of Fig. 2, will provide some useful harmonic attenuation. On the other hand, the circuit of Fig. 3, for some settings, will act as a high-pass filter and provide no useful harmonic attenuation.

The best approach probably is not to expect dual benefits from a tuner. If harmonics are a problem, a good low-pass filter should be used and the tuner left to function solely as a matching device.

Can a kW-level tuner be built for $25? One would never think so if one priced all new components, since a simple variable capacitor can run from $20 to $30. The key to building any of the tuners economically is to find good but low-cost parts. It can be done if one is willing to spend a bit of time looking around. The variable capacitors for the tuner of Fig. 3 cost $25 from a new component dealer. The same capacitors, unused but 20 years old, cost $3.95 from a surplus parts dealer who advertises widely in the amateur radio magazines. ■

Kenwood's New 830S

—evolution, not revolution

Having long been a fan of Kenwood's TS-820S, I looked forward with great anticipation to the arrival of its successor, the TS-830S. The 830S, I knew, promised a number of improvements and additions, among them more flexible receiver controls, smaller size, and the capability of operating on the three new WARC bands. I was both surprised and pleased that Kenwood chose to produce a new radio with a tube-type final amplifier, given the current trend toward solid-state finals. My general impression, after living with the TS-830S for about six weeks, is that Kenwood has kept the best features of the 820S, improved the weak areas, and added controls which make the rig more fun to operate.

The Receiver

On receive, the TS-830S covers all nine ham bands, present and future, from 160 through 10 meters. Sensitivity is rated at 0.25 uV, and side-by-side comparisons with other hot receivers show the 830S to be their equal in this area. Typical of Kenwood gear, the audio is superb, even when heard through the small internal speaker. Kenwood engineers must borrow a colleague from the company's high fidelity sound department when designing the audio stages of their ham equipment.

Some of the most obvious differences between the 830S and the 820S involve receiver features. While the basic dual conversion design scheme with i-fs at 455 kHz and 8.83 MHz remains intact, Kenwood has given 830S owners an impressive array of easy-to-use receiver controls, some of which are not present on the 820S. Three of these controls deserve special mention.

Foremost among these is the Variable Bandwidth Tuning (VBT) control. VBT allows you to change the width of the i-f passband from the normal 2.4 kHz all the way down to 500 Hz, if desired. Among other things, this control makes possible some serious CW operation, even without the optional crystal filters. The narrowing of the passband is accomplished by slightly raising the center frequency of one i-f filter, while slightly lowering the frequency of the second i-f filter. The net result is the narrowing of the i-f passband with no change in the center frequency.

The i-f shift function is a holdover from the 820S. This control actually moves the center frequency of the receiver passband by ±1.2 kHz. When used alone, it allows you to shift the whole passband up or down

Kenwood's TS-830S.

slightly to avoid bothersome interference. What really makes this function a winner, however, is its use in conjunction with the VBT control. By narrowing the passband and at the same time shifting it, some rather remarkable feats of reception can be accomplished. On phone, weak signals which might otherwise be buried by off-channel garbage can be brought up to intelligible levels. On CW, it's possible to reduce the passband width to 500 Hz using VBT, then adjust the Shift control to select one of three or four CW signals, all without touching the tuning dial. It's not as complex as it sounds, of course, taking a lot less time to do it than to describe it.

Notch filters are now standard issue on several modern transceivers. Each manufacturer seems to have a different idea about what hams want on this score. As a result, we have several different types of notch filters on current rigs, all of them useful in their own way. Kenwood's notch on the 830S is moderately deep—a bit better than 40 dB—and very easy to find. It does a good job on all single-tone type (carrier) interference and is especially beneficial during phone operation. It has proven less useful than expected on CW, mostly because there always seems to be more than one station I want to notch out. The notch filter gets only a small fraction of the use that the VBT and Shift controls get.

Once you are past the three controls mentioned above, the receiver portion of the 830S becomes more familiar.

Standard equipment includes a good noise blanker with adjustable threshold. The threshold level is a rather touchy adjustment.

Azden's PCS-3000

—the 2-meter rig of the future is available now

Meet the newest Azden 2-meter rig, the PCS-3000. Many of you are no doubt familiar with the original Azden. The new "Series II" unit has a completely different microcomputer system. It covers an 8-MHz range (142 to 149.995 MHz), has eight memory channels, a back-lighted keyboard, provision for three auxiliary offsets (CAP and Air Force MARS are already included), selectable frequency steps of 5 or 10 kHz, and a nicad battery for memory backup. The radio also comes with a free touchtone™ pad kit.

Interesting, you say? Well, there's more. The above are self-explanatory, but some of the features will have to be described in detail. These include the microcomputer acquisition tone, discriminator scan stop, programmable band scan, auto-resume with delay, memory retention of offsets, and repeater input monitoring. Let's look at these one at a time.

Microcomputer Acquisition Tone

When you first switch on the PCS-3000, it will make a short "tweep" sound. Each time you press one of the buttons on the 12-key microcomputer control keyboard, you'll hear the same sound. The first time I experienced this, I found it to be quite entertaining. But it's very informative as well. Once you get used to it, it's hard to feel comfortable without it. I sup-

The PCS-3000 measures 6-3/4 inches wide by 2-3/8 inches high by 9-3/4 inches deep. The unit comes apart into two pieces: the "control head" (which houses the microcomputer and displays and is 6-3/4 inches wide by 2-3/8 inches high by 2-5/8 inches deep) and the "main unit" (containing the transmitter and receiver circuits). In my car, only the control head is actually mounted under the dashboard, saving much space. The main unit is under the passenger seat. An optional interconnecting cable provides the electrical interface between the two units.

pose it provides some kind of psychological reinforcement, removing all doubt that the microcomputer has gotten the message. All psychoanalysis aside, though, I like this feature.

Discriminator Scan Stop

The PCS-3000 makes use of an exclusive circuit which requires two conditions for the scanner to stop: presence of carrier and frequency centering. Unless the carrier is within a certain range of center frequency, the scanner will keep on going. This circuit allows the radio to scan in steps of 5 kHz without stopping one channel too soon. (Although the carrier is inside the passband when the receiver is 5 kHz below frequency, it isn't centered, so the scanner does not stop.)

Programmable Band Scan

Any section of the frequency range 142 to 149.995 MHz can be scanned in increments of either 5 kHz or 10 kHz. The lower- and upper-limit frequencies are stored in memory channels 7 and 8, respectively. In general, it's probably best to program the lowest commonly used channel into memory 7 and the highest one into memory 8. I programmed 146.52 into memory 7 and 147.00 into memory 8.

The offset in the band-scanning mode is determined by the offset written into memory 8, except for the lower-limit frequency offset, which is the offset stored in memory 7. In my case, channel 7 was programmed for simplex and channel 8 for −600 kHz. The rig was thus set up for simplex at .52 and −600 split at all the other scanned channels.

Auto-Resume with Delay

There are three scanning modes, F, B, and V, chosen by the front-panel Scan/Offset switch. These letters

✓ Reader Service—see page 130

designate free sampling, busy, and vacant scanning modes.

In the F position, the scanner goes along until it hits a busy channel, and then it stops for about 5 seconds. During this time, you can choose either to remain on frequency (by pressing a certain keyboard or microphone button) or to continue scanning (by just waiting). If you decide to continue scanning, the unit will start up again after the 5-second delay and continue until it gets to the next busy channel, where it will stop again for 5 seconds, and so on.

In the B position, the radio scans until it hits a busy frequency and then stops. If the carrier drops out, the unit will start scanning again after a delay of a second or so. Again, you can choose whether or not to stay on frequency by means of the same stop command buttons.

Sometimes I have wanted to stay on frequency but forgot to press a stop command button. The short delay before the radio resumes scanning is very helpful here, because the repeater will usually come back up again before the delay time is up.

In the V position, the radio skips over busy channels and stops at vacant ones. If a signal comes on, the radio moves up to the next vacant channel right away, unless a stop command key has been pressed.

General:	
Semiconductors	IC 18, FET 7, Tr 36, Di 61
Frequency Band*	142.000 – 149.995 MHz
Ambient Temp. Range	– 10 to + 50 degrees C
Antenna Impedance	50 Ohms, resistive
Power Supply	+ 13.8 V ± 15% negative ground
Current Consumption*	0.7 A maximum (receive) 5.0 A maximum (transmit)
Dimensions, overall*	HWD 62 x 158 x 246 mm 2.4 x 6.2 x 9.7 in
Dimensions, head only*	HWD 62 x 158 x 65 mm 2.4 x 6.2 x 2.6 in
Weight*	Approx. 2.5 kg 5.5 lbs
Transmitter:	
Carrier Output*	25 Watts (high), 5 Watts (low)
Emission Type*	F3 by varactor modulation of vco
Frequency Deviation	± 5 kHz maximum
Spurious Output	Down at least 60 dB from fundamental
Microphone	500 Ohms, dynamic
PL Tone Frequency	67 to 250 Hz, adjustable
PL Tone Deviation	0 to ± 1 kHz, adjustable
Receiver:	
Receiving System	Double conversion superheterodyne First i-f: 16.90 MHz Second i-f: 455 kHz
Sensitivity	0.28 uV or better, 20-dB NQ 0.19 uV or better, 12-dB SINAD
Selectivity	± 6 kHz or more at 6 dB down ± 15 kHz or less at 60 dB down
Audio Output	2 Watts or more into 8 Ohms, 10% THD
Accessories, Standard:	
Auxiliary Offset Provision*	Three available
Auxiliary Offset Built In*	Air Force MARS: – 1.305 MHz CAP: – 4.250 MHz
Dynamic Microphone*	500 Ohms
Built-In Speaker*	8 Ohms
Mobile Mounting Bracket and Hardware*	
Accessories, Optional:	
Auxiliary Offset Crystals	Parallel resonant 20 pF, HC18-U holder
CS-ECK 15-foot Remote Cable	$35.00
CS-6R 6-Amp ac Supply	$59.95
CS-AS 8-Ohm Remote Speaker	$18.00
CS-TTK Touchtone Microphone Kit	$39.95

Table 1.

Memory Retention of Offsets

Each of the eight memory channels retains a frequency and one of three offsets (simplex, −600 kHz, or +600 kHz). Programming is simple. Just dial up the desired frequency and offset, set the memory address to the appropriate channel, and press M WRITE. When that channel is recalled, the receiving frequency is displayed while receiving and the transmitting frequency is displayed while transmitting. Pure and simple!

Repeater Input Monitoring

There is a little switch on the side of the microphone labeled "CH LOCK." When this switch is actuated, the *receiver* goes to the *transmit* frequency. If you transmit, the transmitter frequency remains as programmed. This feature is useful if you want to listen to the repeater input frequency instead of the output frequency.

Keyboard Operation

It takes quite a while to learn the operation of this very advanced and sophisticated radio, and I certainly am not going to try to cover all the details here. What I'd like to do, though, is give you some idea of how the thing works, and some idea of how versatile it really is. So let's look at the keys, briefly, one at a time.

The MHz UP key advances the MHz figure only, in the range of 2 to 9, in upward steps of 1 MHz. That is, as this key is pressed over and over, the MHz figure changes in the sequence 2, 3, 4, 5, 6, 7, 8, 9, 2, 3, and so on. No other digits are affected.

The 100K UP key advances the 100-kHz digit upward without changing the MHz figure or the unit kHz figure. Example: You have the frequency 6.940 displayed and actuate the 100K UP key, giving a new display of 6.040. Actuate the 100K UP key again, and the display becomes 6.140. The 100K DOWN key reverses this, so if you have 6.140 and hit the 100K DOWN key twice, you will be back on 6.940. It takes a little getting used to.

The 5/10K UP key advances the unit kHz digit by either 5 or 10 kHz, depending on the setting of a push-button lock switch on the front panel. Suppose this switch is set for 5-kHz steps and you are on 6.940. Hit the 5/10K UP key and you go to 6.945. If you actuate this key over and over, the frequency will increase by 5 kHz steps until you are at 6.995, and then it will go down to 6.000. The frequency is thus tunable within a 1-MHz range using this key. By holding the key down, the radio will move upward very rapidly in 5-kHz steps. This gives a "vfo" feeling. The 5/10K DOWN key just reverses the process of the 5/10K UP key.

The BAND SCAN key causes the radio to scan in steps of 5 or 10 kHz (as selected by the push-button lock switch I mentioned above) between two limit frequencies which can be selected at will by the operator. The lower-limit frequency is the channel in memory 7 and the upper-limit frequency is the channel in memory 8. Band scanning starts at the lower limit and moves upward.

The ±600 SHIFT key puts the radio in the simplex, −600, or +600 offset modes by repeated actuation. Just to the left of the frequency display, small LEDs indicate the offset.

The five keys M ADRS, M SCAN, M1 CALL, M CALL, and M WRITE accomplish memory programming, re-

call, and scanning. The functions of these keys are pretty much self-explanatory. Memory can be easily reprogrammed. When power is turned off, memory is held by a nicad battery that is constantly charging while the radio is on. You can therefore put the radio away for a few weeks, put it back on the air, and you'll still have the same memory channels and offsets.

Inside the Radio

The PCS-3000 uses modular construction (as any state-of-the-art radio does nowadays, after all). Interior layout is neat and rugged. Circuit boards are secured to the heavy-duty chassis with several screws. The vco/PLL section is isolated electrically by means of a shielded enclosure and is padded with wax to minimize microphonics. The layout is orderly and the component designations are marked on the boards.

All circuit boards are easily removed and replaced, since all interconnecting wires unplug and their pin positions are clearly marked. Taking one of the boards out of the radio and visually examining the underside, it is apparent that the manufacturers have taken care to do a neat job of soldering. There are no sloppy connections, bridges, or cold joints.

The control-head section of the PCS-3000 is greatly miniaturized, but the logical modular construction will make it easy to service.

Internal adjustments of PL tone frequency, PL tone deviation, high power and low power, as well as auxiliary offset crystals, are located on the PC board on the top of the main unit. PL tone frequency is adjusted by a blue pot, VR412; PL level is adjusted by VR411 (these are both near the

Battlewagon

—tales of a mini-expedition to the USS Texas

Photos by Smitty Kiker KB5UM

Battleship TEXAS

Confirming your contact on ________ - meter single sideband with members of the North Texas High Frequency Association operating portable on the quarterdeck of The Battleship TEXAS from 1700Z May 17 to 1700Z May 18, 1980. Equipment included a Yaesu FT7 with 100 watt amplifier on 20 meters and a Kenwood 520 and Swan 500C on 15 and 40, working into inverted Vee antennas strung to the ship's superstructure. Thanks for the contact and 73 from all NTHFA members.

For those of you who missed out on last year's happening, these crazy people will return (with more equipment!) to the USS Texas *for Armed Forces Day weekend, this May 16 and 17. Look for the pileups on 10 through 40 meters, around* 28,550-75, 21,375, 14,300, and 7.245. *A special QSL will be available, but please include an SASE. All visitors are welcome, and if you would like to operate, stop by and say hello. Listen for WB5TSB (Texas State Battleship).*

The ship's "crew:" Kneeling, from left, Smitty Kiker KB5UM; Phil Huckaba KB5VX; Rudy Littrell N5BKQ; Robin Wilson N5BTU; C. J. Taylor N5BKA. Standing, from left, George Watkins WD5FNI; Fred Opaskey WB5TSB; Gary Fellers K5LQP; Al Faubion KA5HLS; Roy Moses WD5ICY; Dennis Jump WB6OCQ/5; J'Nevelyn Faubion KA5HJS; George Lindley WA5HKW; Capt. Robert Martin; and Pat Brannon N5AIZ. Not pictured, Duncan Engler WD5IKY and Dale Gant WB5TWO.

The eight-car caravan of amateur radio operators drove the last 100 miles to Houston in a steady rain, ranging from light showers to torrential downpour punctuated with cloud-to-ground lightning, hail, and gusty winds. The earth, subjected to double-digit rainfall the preceding two days, could absorb no more. Every creek and ditch was bank full and then some.

The National Weather Service predicted more of the same for the next 24 hours, offering grim prospects, indeed, for the success of the event scheduled to kick off at noon the next day.

Those in the caravan were members of the North Texas High Frequency Association of Denton, Texas, some 300 miles to the northwest, and their objective was the battleship *Texas*. Purpose: A mini-expedition to operate portable for 24 hours from the decks of the old warship. It was a hastily-planned operating event that was to capture the imagination of hundreds of hams around the world.

But whatever gods watch over hams, keeping them from falling headlong off antenna towers or frying their body parts with uncontrolled ac, must have had their eyes on these amateurs, too. They arrived in Houston in rain and returned to Denton in rain, but in between they were favored with bright sun, blue skies, and gentle Gulf of Mexico breezes, offering operating conditions nothing short of superb.

Only one small glitch marred the entire three-day outing. A communications breakdown made the dockside arrival of the Denton hams a total surprise to the battleship *Texas* crew, but that temporary setback proved so minor as to become totally inconsequential.

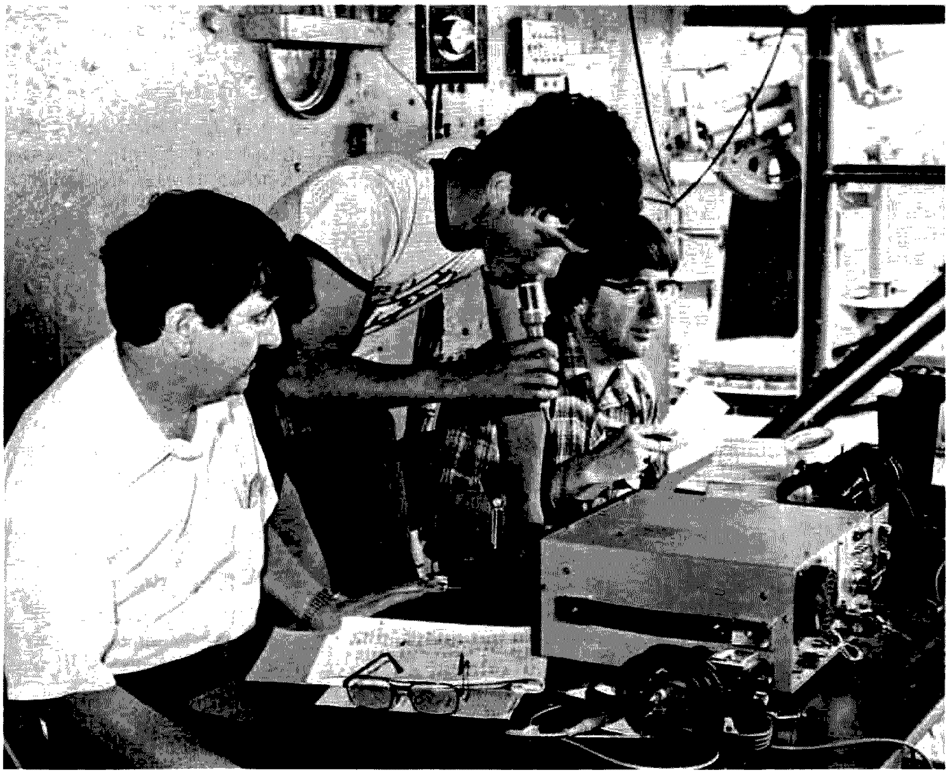
The idea for the battleship mini-expedition, like the brainstorm that resulted in the group's first mini-expedition in the fall of 1979 (Working 'Phone From Telephone, Texas), was hatched one night over post-meeting coffee and doughnuts. As with the first expedition, the idea smouldered a bit at first, but soon caught fire, and by the time final plans were being made, almost half of the Association's 45 members had signed up to go. Last-minute complications cut that number to 16 licensed hams with a total traveling party of 33, counting wives and children.

As with all of the club's special activities, an ad hoc operations chairman was appointed to head the event. This job was filled admirably by George Watkins WD5FNI ably assisted by George Lindley WA5HKW, the organization's secretary-treasurer.

The *USS Texas* was commissioned in 1914, served in two world wars, then was decommissioned and donated to the state of Texas in 1948. It was declared a State Historical Monument and permanently berthed on the edge of the Houston Ship Channel in San Jacinto State Park, an area southeast of downtown Houston. That location marks the site of the decisive battle in 1836 in which the Republic of Texas won its independence from Mexico.

So, the first order of business was a letter to the State Parks Board, seeking permission for the undertaking. The response said that although the ship was berthed in a state park, it was operated under auspices of the Battleship Texas Commission, and the request was forwarded to that body. Another short wait and the response said such an operation was certainly

Stringing antennas, from left, are C. J. Taylor N5BKA, George Lindley WA5HKW, club secretary-treasurer, and George Watkins WD5FNI. In background is Dennis Jump WB6OCQ/5. Shortly after the mini-expedition, Watkins was elected president of the North Texas High Frequency Association for 1980-81.



Bob Dills W5RWW of Dallas, left, was vacationing in Houston when he got put to work. It was Bob's first operating on the HF bands in quite a while, since he sold his HF gear some years ago. Pat Brannon N5AIZ is about to hand the mike over to Bob while Gary Fellers K5LQP handles the logging.

permissible and should be coordinated with the *Texas's* skipper, Capt. Robert Martin. A follow-up phone call to Capt. Martin put the operation on the front burner.

The target date was set for the weekend of May 17, which turned out to dovetail quite nicely, albeit accidentally, with Armed Forces Day. By mid-April, most logistical plans had fallen into place, even though Watkins complained, "This whole operation will probably be a failure—we're doing too much planning." The NTHFA, which has grown from eight to almost 50 members in less than two years, has more or less prided itself on "organized disorganization" and improvisation. Three telephone calls to Houston seemed a little much.

As the date drew nearer, certain firm decisions were made: Operate two rigs on 15, 20, and 40 meters as band conditions dictated, from noon Saturday, May 17, to noon Sunday, May 18, local time; use inverted-vee antennas strung to the ship's superstructure; use the call of member Fred Opaskey WB5TSB (*Texas* State Battleship, phonetically); operate primarily in the lower portions of the General class phone bands; no QSL or SASE required (the club would finance printing and mailing confirmations); and make as many contacts as possible. But, operations would not emphasize contest-style contacts—ragchewing would be permitted at the operator's discretion.

The wisdom of that last decision was to become evident. It was surprising how many former *Texas* crew members, Navy veterans, and just plain ship buffs wanted to ask about the old battlewagon, her armament, and her present

condition. About mid-way through the 24-hour operation, Treasurer Lindley made a quick check of the two logs, then issued the tongue-in-cheek order, "Stretch out each contact; the postage is going to kill us!"

The Denton group arrived at dockside at 9:00 am Saturday morning, an hour before the ship is routinely opened to the public, to encounter that minor setback—nobody knew they were coming that weekend! Watkins, with the charm of a Rhett Butler at an Atlanta ball, conferred briefly with the executive officer, who made a quick phone call to Capt. Martin ("those shortwave guys are here"), and the red carpet was rolled out.

Almost as if planned, but totally by intuition, members undertook the various tasks of unloading vehicles, setting up tables, plugging in radios and accessories, cutting and stringing antennas, and running to a store for the only forgotten item: some screw-in electrical plugs. At 12:02 pm the first station went on the air, on 15 meters, and at 12:03 the first contact was made, with Curt WD6CUN in Anaheim, California. The next contact, a prearranged schedule which was hoped would be the first contact, was with W6RO (Rolling Ocean)—the *Queen Mary* in Long Beach, sort of "maritime immobile to maritime immobile."

The 20-meter antenna required a bit more pruning and the second station went on the air about 12:30 pm. It required a few minutes to find a hole in the heavy QRM, and the first contact came at 12:33, with Norm KB4VM, in Powell, Tennessee. That station operated steadily for the next 23½ hours with the frequency never varying more than 5 kHz in either direction from the spot of the

Fred Opaskey WB5TSB operates the 15/40-meter station while Rudy Littrell N5BKQ does the logging. Phil Huckaba KB5VX, left, lends moral support while waiting his turn.

Duncan Engler WD5IKY enjoys watching James "Abe" Abel WD5BIS work a pileup on 15 meters. Abe, who lives in Houston, served aboard the USS Texas as an apprentice seaman in 1936-37. He cut short his vacation to be on hand for the mini-expedition.

Jan (KA5HJS) and Al (KA5HLS) Faubion were among those who got a special tour of the Texas's *radio room, which is not open to the public. Much of the gear is still in place in apparently well-preserved condition.*

first contact.

The battleship *Texas* is open daily, 365 days a year, to the public, from 10:00 am to 5:00 pm, and since the two stations were operating in the open on the quarterdeck, they became centers of interest for many of the tourists—hams and non-hams alike—visiting the ship.

The equipment consisted of a Yaesu FT-7 with a companion 100-Watt amplifier for the 20-meter station, and a Swan 500C running barefoot through a Den-Tron Super Tuner Plus for 15 and 40 meters. In the wee hours of Sunday morning, when the Swan showed symptoms of losing its spunk, a Kenwood 520 was substituted, although the problem later proved to be one of metering rather than output. The Yaesu and linear were operated on an automobile battery connected to a 6-Amp charger and the Swan and Kenwood rigs were plugged into the ship's power system.

Most non-ham visitors indicated a vague awareness of amateur radio, but their intrigue became considerably more evident when they heard QSOs in progress, especially with stations several thousand miles distant. One of the most enthralled was Toni Tucker, a teenage clerk in the ship's gift shop. She utilized her afternoon coffee break to visit one of the stations and didn't bat an eye when operator Dennis Jump WB6OCQ/5 handed her the microphone and said, "Talk to this guy in North Carolina." But the *Texas*'s PA system shortly terminated her third-party operations with the announcement, "Will Toni Tucker please report back to the gift shop . . . immediately."

Numerous questions were asked by visitors, but the most prevalent seemed to be, "Why are you doing this?" About the best answer the amateurs could come up with was, "Because it's never been done before."

Of the amateurs who dropped by, a few were quickly put to work, and none enjoyed it more than James "Abe" Abel WD5BIS of Houston, or Bob Dills W5RWW of Dallas. Abe had learned of the mini-expedition a few weeks earlier in a 40-meter QSO with Duncan Engler WD5IKY. He was excited because he had served on the *Texas* as an apprentice seaman in 1936-37, but he was disappointed because he had made vacation plans and would be in Tennessee that weekend. But he couldn't resist the opportunity. Abe cut short his vacation and drove nonstop from Tennessee to spend several hours visiting and operating on the *Texas* Saturday afternoon.

Bob had been inactive on HF since he sold his HF gear a few years ago. He was vacationing in the Houston area, heard about the battleship operation via 2-meter repeater, and made it a point to drop by. His arrival came late Sunday morning, when operators' energies were ebbing rapidly, and somebody shoved a mike into his hand and said, "Talk to 'em." He did, for about the last hour that the 15/40 station was on the air. Bob's wife, Barbara, sat patiently in a shady spot nearby. She said with a smile, "He's having the time of his life."

At noon, Sunday, operators at both stations were still working pileups, so it was with considerable reluctance that apologies were made to those still standing by, and Willie Baker Five Texas State Battleship signed clear. The NTHFAers hated to disappoint those who had waited so patiently for a contact, but the seven-hour drive home loomed large in the red-rimmed eyes of the weary operators, especially the 11 who had spent the night on board.

The convoy home was uneventful, and the intervehicle chatter on .52 simplex became more and more subdued as the miles rolled by. Highlight of the return was qualifying three hams for "Worked All Denton" awards for working five or more members of the Association. The first two were Charles WA5FMK and Agnes WB5VWB Ellisor of Houston, who passed the group near the outskirts of the city and became curious about a convoy of so many Texas amateur radio operator license plates. They struck up a conversation on .52 and, since they were near home, subsequently got on their fixed station and continued the QSO for several miles, working each vehicle, in order, down the convoy.

The other WAD award went to Jimmy McCarter WD5DFQ of Mesquite, Texas, when he passed the convoy on Interstate 45 about 100 miles south of Dallas. He, too, was curious about the license plates, but a convoy member made the first call to inquire about an unusual-looking homebrew mobile HF antenna on Jimmy's bumper.

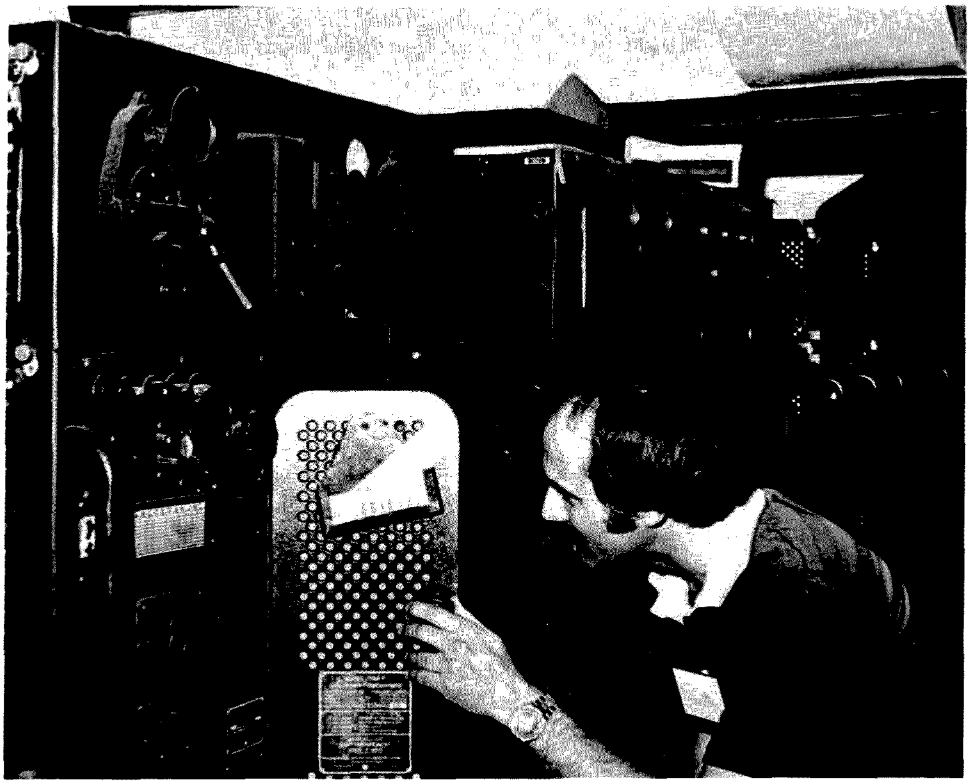
The box score for the mini-expedition went like this: 771 total contacts, plus a couple of SWLs. The total could have easily gone over 1,000 had the operation been handled contest-style. The contacts included 46 states, two VEs, nine foreign countries, and three maritime mobiles.

A special QSL card was printed and mailed to all contacts, except for a few whose addresses could not be verified, and return cards and letters trickled in to NTHFA members for weeks. One operator sought the battleship confirmation so fervently that he wrote one letter and two cards because he had antenna problems and was unsure if his brief contact was logged. "I'll understand if I'm not in the log," he wrote, "but at least send me an SWL card . . . please."

It was surprising how many contacts were made with amateurs who had a firsthand knowledge of the old ship, having served on her, worked on her, or at least been on or around her at one time or another.

"I remember the *Texas* well," said one contact. "She was escorting a convoy that I was in across the North Atlantic in the early forties, and it sure was a good feeling to look out on the horizon and see that battlewagon steaming along beside us. I remember her well."

So will members of the North Texas High Frequency Association. ■



Rudy Littrell N5BKQ examines some of the old gear in the Texas's *radio room, which is not open to the public. A battleship crew member gave several of the visiting hams a special tour of the below-decks area.*

Dennis Jump WB6OCQ/5, a transplanted newcomer to the club, was told that sixes have to work harder—and he did. Dennis finally managed a short nap about daylight, Sunday morning.

Inside Coax

—know what you're buying in quality and construction

Coaxial cable seems to be one of those products where any old brand will do. Just use RG-8/U for high power and RG-58/U for low power. Yet, few hams realize that a typical 300-Watt rig can lose more than 100 Watts in certain types of coaxial cable. Also, few realize that RG-8/U varies from manufacturer to manufacturer in TVI prevention capability.

The fact is that RG coaxial cables are different, varying in performance from one manufacturer to another. Cost should not be a major consideration in selecting coaxial cable. Many hams will spend thousands of dollars on a rig, tower, and beam and then scrimp on cheap coaxial cable which eats up transmitter power or S-units!

Prior to World War II, coaxial cable was unheard of. Open-wire balanced line was the standard transmission line. However, with the advent of television, open-wire line was a liability—it radiated rf into many places where it was unwanted. Open-wire feedlines also had a nasty habit of radiating weak harmonics. The solution was to design a transmission line that did not radiate rf itself, so coaxial cable was developed. These early cables were given RG designations and usually manufactured to military specifications.

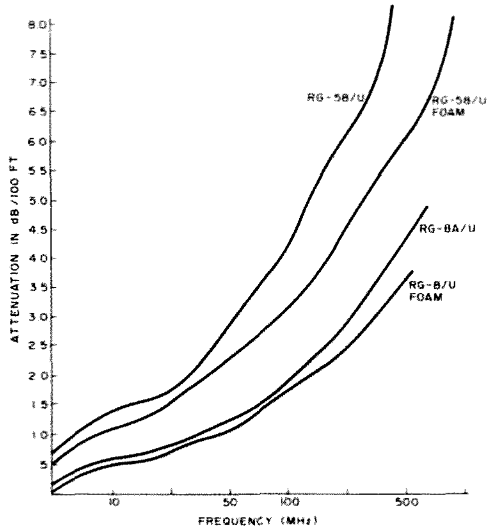

Fig. 1. Attenuation with regard to frequency.

Cable Selection

Since coaxial cable now is taken for granted, few amateurs realize the differences between one cable and another. If a construction article calls for RG-8 or RG-58 coaxial cable, most amateurs assume that any brand so labeled will do the trick. Nothing could be further from the truth. Just what does the RG- /U designation mean? The RG- /U designation refers to a standard military designation for cable which meets certain specifications and test requirements. A new set of updated standards was released by the military in 1978. The new requirements were designed to provide improved coaxial cable standards and are referred to as MIL-C-17E specifications. The basic specifications advanced by the military are covered in the following:

1) Center conductor—type, diameter.
2) Dielectric—composition, diameter, tolerance.
3) Outer conductor—type, number of braid layers, gauge of braid wire, percent braid coverage.
4) Outer jacket—composition and diameter.

If a cable meets the requirements and tests as outlined in the military specifications above, it is designated as meeting an RG specification. However, just because a cable is labeled as RG-8/U by the manufacturer does not ensure that it meets any of the criteria spelled out in MIL-C-17E.

Because coaxial cable is taken for granted, it is well worth spending some time evaluating which cable is best for you. The only reliable means of selecting cable is to evaluate the test data supplied by the manufacturer. There are manufacturers who do not have test facilities or the skills to actually test the cable they produce. Some don't even know what the impedance of their cable is! The military specifications provide a good set of items to evaluate your needs.

Center Conductor

The center conductor of RG-8/U-type cable should consist of seven 21-gauge bare copper wires. RG-58/U variations come with either 19 tinned 33-gauge copper wires or a single 20-gauge bare copper wire. The choice between stranded and solid conductors is easy; if the transmission line is subject to twisting or flexing, then use stranded

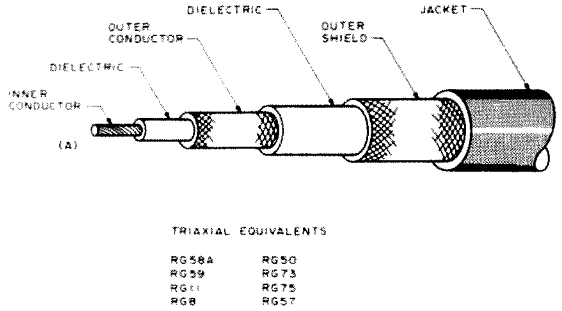

Fig. 2. Triaxial cable construction.

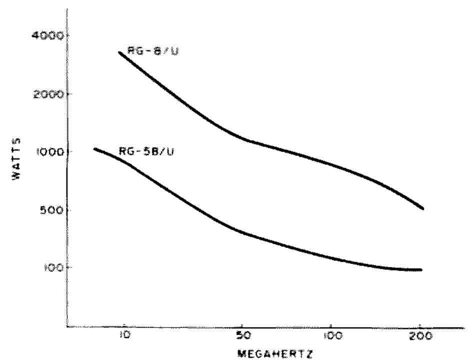

Fig. 3. Power handling capability with respect to frequency.

conductor. Typically, stranded conductor is less efficient than using a single-wire center conductor.

Dielectric

Currently there are a variety of materials being used for dielectric material. The two most common are polyethylene and cellular polyethylene or "foam." Polyethylene cable should be constructed of solid virgin polyethylene. Cable with an amber or gray color was probably made from reclaimed polyethylene scrap. Often there are bubbles in a cross section of this type of cable. This causes line imbalances, creating "loss points" along the line.

The newer and more popular dielectric material is formed by expanding virgin polyethylene with a special foaming agent. This foam dielectric has a dielectric constant of 1.5, compared to 2.26 for regular polyethylene dielectric material. The dielectric constant is very important because the closer the dielectric constant coefficient of a given cable is to 1.0, the lower the attenuating ability of that cable. The dielectric constant is also important for another reason. The dielectric between the center conductor and the outside braid forms a capacitor, and this capacitance can amount to a significant quantity. Consider the typical ham with 100 feet of RG-8/U feedline. RG-8/U has 29.5 pF capacitance/foot, while the foam coax version of RG-8/U has 24.5 pF/foot. This difference alone amounts to 500 pF. This capacitance is equivalent to a large loading capacitor across the pi network of a transmitter. This difference becomes important when evaluating coax cable for VHF work.

There is another consideration with respect to attenuation. As can be seen from Fig. 1, the attenuation of coax cable rises with frequency.

Every time you boost your radiated signal strength by 3 dB, it is the equivalent of doubling transmitted power. A simple example will help here. Compare 100′ of RG-58/U with 100′ of foam RG-8/U on two meters. The RG-58/U will lose almost 6 dB, while the RG-8/U foam cable will lose a little more than 2 dB. In other words, you would need to more than double the power with RG-58/U to achieve the same results as with foam RG-8/U.

Outer Conductor or Braid

The most visible area for spotting defective coaxial cable is in the percent of braid coverage. A good grade of coaxial cable will have at least 95% of the dielectric covered with a braid of 36-gauge copper wire. Good braid coverage is essential for TVI prevention. Double shielded coax cable can be purchased to provide 100% braid coverage. Belden 9888 is an example of double-shielded RG-8/U. Another reason to select cable with good braid coverage is because reduced attenuation occurs for cable that has the shielding characteristics of a metal tube.

An exotic variation of double-shielded cable is triaxial cable, which consists of a second dielectric between the first and second braid (see Fig. 2). This type of cable is very effective at preventing TVI from being radiated and, unfortunately, is also very expensive.

Jacket Composition

Perhaps one of the most crucial factors affecting the average coax's ability to radiate a signal is the chemical composition of the outer jacket of the cable. Most coax cable jackets are composed of black or grey polyvinylchloride. However, there are two types: type I and type IIa. The only way to distinguish between these two is to look for an "A" after the numbers in the cases of RG-8/U (RG-8A/U) and RG-59 (RG-59A/U) cable. For RG-58/U, a "C" will indicate a type IIa jacket (RG-58C/U). RG-213/U is a 50-Ohm version of RG-8A/U that has a type IIa jacket.

Type-I jackets work well until the temperature rises. When the temperature rises, the "plasticizer," a chemical added to the outer jacket to keep it soft and flexible, begins to leach through the outer braid and into the dielectric. This changes the electrical characteristics of the coax cable. Attenuation coefficients increase, characteristic impedances change, and, of course, so will swr. This leaching effect can be seen if you have any old RG-8/U or RG-58/U cable around. Strip off the outer jacket and the copper braid. If the dielectric material has a hazy black tint, then the leaching process has occurred. Good dielectric material will have a characteristic milky-white color, without a trace of black coloring. This leaching process occurs with or without heat, but heat accelerates the leaching process. Thus, buying old, unused coaxial cable is rarely the bargain it might appear to be. Old cable with a type-I jacket is probably useless as an rf carrier.

Type-IIa jackets, on the other hand, use a different method of plasticizing the jacket, with the result being the virtual elimination of the leaching effect. Thus, cable with a type-IIa jacket will last longer as transmission line. The point is simple—don't purchase coax cable unless it has a type-IIa jacket.

Power Ratings

Power ratings, like attenuation characteristics, are affected by frequency (see Fig. 3). These ratings assume a low swr which, if not present, will further reduce

the power-handling capability of the line. The point here should be obvious—don't try to feed a kilowatt into RG-58/U on two meters. It is important to know the power-handling capabilities of the cable you use, not just in general, but for the specific frequencies you plan to use.

Impedance

The critical question here is tolerance. Factors such as percent braid coverage, diameter and composition of dielectric material, and the type of outer jacket material all affect cable impedance. If a power-consuming mismatch is to be avoided, then the cable should be within 10% of its specified impedance. Usually, the tolerance of a cable can be found in the manufacturer's specification sheets. Often, when you go to the local store, specification sheets aren't available. You can play it safe in this situation by sticking with a major brand manufacturer.

Conclusions

By following the points mentioned above, you can usually avoid purchasing second-rate coaxial cable. The best cable you can buy will meet MIL-C-17E specifications. You probably won't find MIL-C-17E cable in your local ham store, and if you do, its price might shock you. The usual high quality cable in your local ham store will probably meet the previous MIL-C-17*D* specifications and won't cost as much as MIL-C-17E cable. However, MIL-C-17D specification coax cable will be adequate for most average ham use. ■

Note: Another cable worth considering is RG-8X. This grey coax is half the diameter of RG-8, displays similar attenuation and power handling characteristics (75%), and is an excellent buy.—Ed.

The "No Antennas" Antenna

—a coaxial dipole is one woman's solution to problems with pesky landlords

Are you one of the unfortunate few who happens to be an apartment dweller ham? And is your landlord or apartment manager one who forbids outdoor antennas of any sort? If so, this article may be for you. The problem of erecting an antenna in a "no antennas outdoors" situation is a tricky one, indeed. This limits one to indoor antennas, the logic being that what is not seen will not be noticed.

After experimenting with many different types of indoor antennas, all with disastrous results and much TVI, I finally came upon a coaxial dipole suggested by a fellow ham friend. This antenna appealed to me because of its greatly attenuated harmonics, thus lessening the TVI problem. Unlike a conventional dipole, this antenna is very broadbanded, covering from 500 kHz to 1 MHz, depending upon band used, and with an swr under 2:1 at band edges.

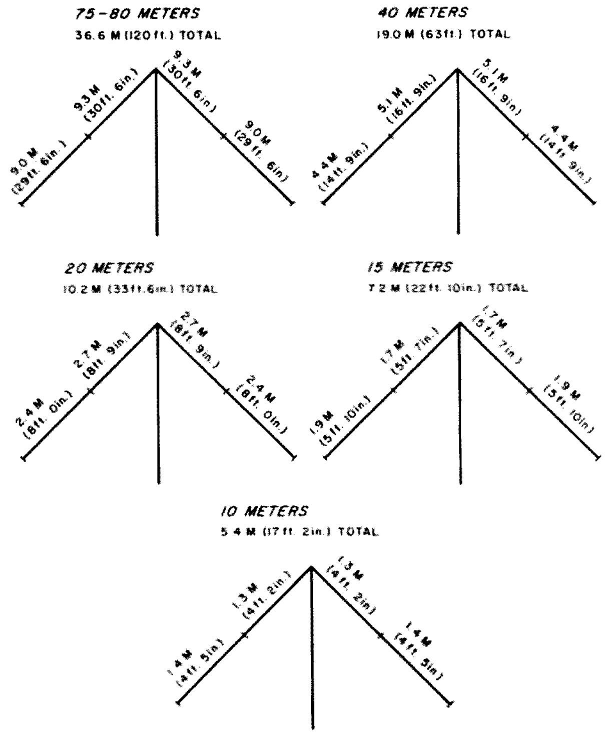

Fig. 1. Antenna lengths.

Its broadband characteristics are due, in part, to the feedline being matched to the antenna and the electrical incorporation of its own balun, with the result that no add-on antenna tuner or balun is required. The coaxial dipole has a slight amount of gain over a conventional dipole, and since the vinyl jacket covers the entire antenna, it reduces static charge build-up considerably, which causes a popping noise in the receiver when discharged. Thus, the coaxial dipole is a very "quiet" antenna with slightly stronger signal punch than a conventional dipole.

Construction of the antenna is simple. One may use either RG-8/U or RG-58A/U coax, the latter being lighter in weight and easier to work with. Maximum legal power can be used with either choice of coax. For antenna lengths, see Fig. 1. The 40-meter antenna will be used as an example.

Begin construction by removing 2.5 cm (1") of vinyl jacket (1/2" each side of center) at the center of the antenna. Cut the shield in the center all the way around the coax. Care must be used so that you do not cut the dielectric or the center conductor. Next, form two leads with the shield as shown in Fig. 2. This is the feedpoint of the antenna.

From this center feedpoint, measure out each side of center 5.1 m (16' 9") and cut the coax at that point. Remove approximately 2.5 cm of vinyl jacket from each of the ends and fold back the shield so that the dielectric is exposed. Cut and remove about 2.5 cm of this insulation, being careful not to cut the center conductor. Then twist the shield and center conductor together and solder. This must be done at both ends and forms the 52-Ohm match-

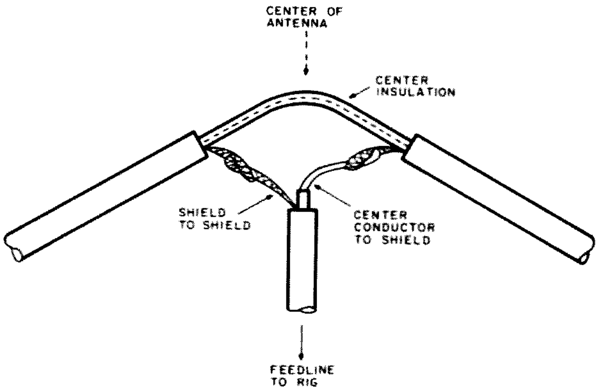

Fig. 2. Feedpoint connection.

ing section and balun.

Next, cut two lengths of coax, each 4.4 m (14′ 9″) long. Then remove 2.5 cm of vinyl jacket from all four ends, fold back the shield, remove center insulation, and twist shield and center conductor together as before. This forms the end sections of the antenna. Attach one of these end sections to one end of the matching section by twisting together the prepared ends and soldering. In the same manner, solder the remaining end section to the other end of the matching section. Waterproof these joints as best you can. Waterproofing of the ends will be done later, for they may need cutting for tuning purposes.

The next step is to attach the feedline. Any random length of coax will do, but it must be of the same type used for construction of the antenna. Remove approximately 2.5 cm of vinyl jacket from the end of feedline, fold back the shield, and remove center insulation. Form two leads with the shield and center conductor. At the feedpoint of the antenna, connect the feedline by soldering the feedline center conductor to one of the feedpoint leads. Then solder the feedline shield to the remaining lead. You may wish to waterproof this area, making sure that the feedpoint leads do not touch each other and short out. Follow this procedure for antennas on other bands.

Erecting the antenna is next. If you have access to an attic or crawl space in the roof of your apartment building, so much the better. Using monofilament fishing line as anchor ties, a series of half hitches along the vinyl jacket ends of antenna will do nicely for anchoring the antenna. The monofilament line will bite into the vinyl as it is pulled taut.

If you are not fortunate enough to have access to an attic, the antenna may be stapled to a living room or bedroom ceiling using plastic cable ties or any other non-conducting material as support. Wrap the cable ties around the antenna at intervals and staple the free end(s) of the ties to the ceiling. Do not staple directly through the antenna itself.

This antenna can be used as a dipole or inverted vee. If used as a dipole, try to erect as much of it as possible in a straight line, keeping it as far away from large metal objects as feasible. The ends may hang down as long as they don't touch any nearby metal objects. More than one antenna may be erected in the same area, providing they are run at angles to each other rather than being parallel. The reason for this is that the inactive antenna could absorb some signal from the active antenna, thereby attenuating the signal output.

After erecting the antenna, check swr and trim the ends if needed. Be sure to twist the ends of the antenna as before (shield to center conductor), then recheck swr. The antenna will interact with any hidden wiring in walls, so a considerable amount may have to be trimmed from each end. Once you have gotten the swr down to an acceptable level, solder the ends of the antenna and waterproof them if desired. This completes construction.

Aside from a low-pass filter, no other add-ons are needed, the filter being only a safety precaution. And, since the antenna is basically omnidirectional, orientation can be determined by the space available at your location.

Once you start enjoying the pleasures of operating from your apartment with this antenna, you will be amazed at what you can work and the signal reports you get with it. I have used coaxial dipoles on 10, 15, 20, and 40 meters from an apartment, and all are stapled to a ceiling in "inverted-U" fashion rather than as an inverted vee. Signal reports received vary from S-6 to 60 dB over S-9. TVI is minimal, considering my TV is only a mere ten feet from the antenna and I run 200 Watts PEP.

With these coaxial dipoles in use for over two years now, I have gotten Worked All Continents, Worked All States, and DXCC with 121 countries worked to date. So there's no telling what you can do with this antenna and you may be pleasantly surprised at the results. It sure beats non-operating just because you live in an apartment! Happy DXing! ■

Slow-Scan in Bits and Bytes

—microprocessors and plug-in cards can give you flexibility on SSTV

When starting on my first slow-scan television (SSTV) project back in 1977, little help was available. To initiate even the most primitive functions required a significant effort. The microprocessor industry has advanced far in these past few years, however, to a point where hardware is available off the shelf for many applications. A home experimenter can create an entire computer system in a few hours simply by selecting cards and plugging them into a common bus where the bus is just a number of common connectors mounted on a PC board.

The concept of picking and chosing components is not a new one. This technique is standard in hi-fi systems. One can buy speakers from one manufacturer, a turntable from another, and an amplifier from a third. Why not apply this technique to computers?

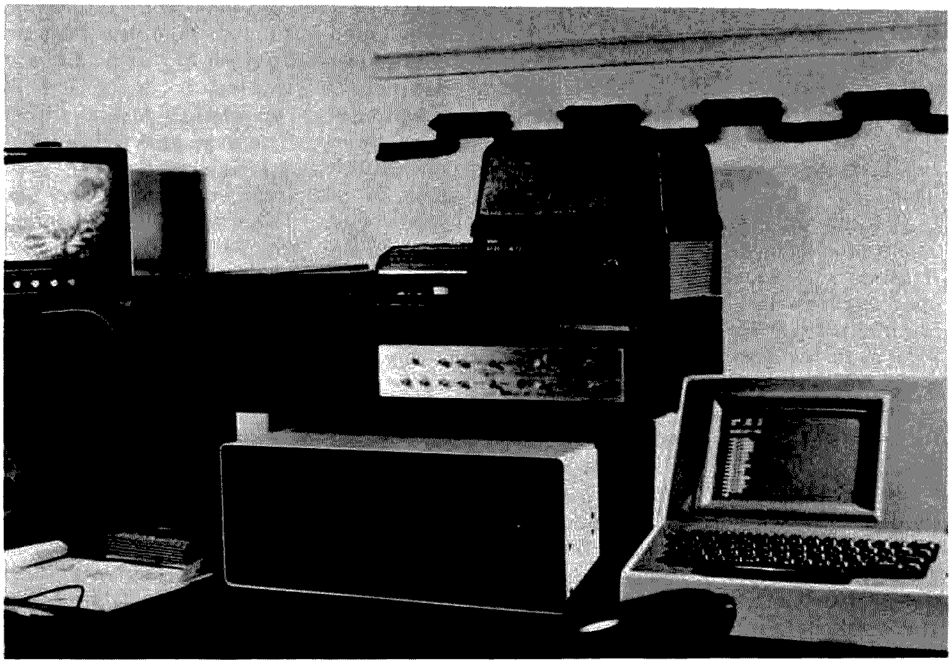

Photo A. Computer installation of K6AEP.

You may ask, how does all of this apply to amateur radio SSTV? In this article I will discuss two components, or cards, which can plug into a common bus to create a microprocessor-based SSTV system. A system of this type, unlike its hardware-only counterpart, has great flexibility. If your ham shack is as congested as mine—see Photo A—you don't have room to install a box which is devoted only to SSTV. With these cards and a general-purpose microcomputer system, an SSTV system with unbelievable flexibility and features can be created. The system can be used for other amateur radio modes, i.e., RTTY or CW, by simple program changes.

Before plowing ahead into pages of technical details, I think a short

review of SSTV is appropriate.

SSTV Description

SSTV is a scheme to transmit and receive television pictures over amateur radio. The pictures have reduced resolution and are slow, hence the name.

SSTV has a bandwidth low enough to be compatible with all amateur transmitters. The pictures are received and generated from audio tones which are varied proportionately to the television rates. Typical tones are 1500 Hz for black and 2300 Hz for white, with in between tones for various gray levels. To synchronize these video frequencies, a tone (1200 Hz) must be provided. All that has to be done to interface SSTV to the amateur equipment is to plug the transmitted SSTV into the microphone jack and the received SSTV directly into the microprocessor.

The Hardware

To make a system like this possible requires the four components shown in Fig. 1. Each component is a product of modern technology and is difficult for the non-computer expert to understand. However, if you treat each component simply as a black box and don't worry about how it functions, interfacing can be easy.

I'll discuss each of the components individually, starting with the two fast-scan interfaces.

1. *The Digisector Television Camera Interface.* The Digisector is an interface card for any standard (NTSC) or non-standard (industrial) television camera. The card is available from a firm in southern California called Microworks.[1] The card is available in three configurations, allowing attachment to a number of microprocessor systems, i.e., IEEE-696 (S-100), SS-50, and Apple. All cards function in a similar manner, as follows: The cards section the TV picture up into a maximum of 256 X and Y coordinates. You can address up to 65k picture locations with the card. The card will respond to the programmed coordinates with a 6-bit (64) gray-level pixel. The card responds very quickly, within 12 microseconds maximum.

The card accomplishes this trick by using a fast sample-and-hold and a medium-speed successive approximation analog-to-digital converter. You program where you want the card to digitize a pixel by loading the X and Y coordinates in their respective ports. The port is connected to two 8-bit comparators which are in turn connected to two counters. The counters are driven by pulses derived from the camera's vertical and horizontal sync. When the programmed count equals the counter, you have a match and the video signal is digitized.

The Microworks people did this using 23 ICs for the DS-68 (SS-50) and 25 ICs for the DS-80 (IEEE-696). They did a great job with the DS-68 in cramming so much circuitry onto a small SS-50 I/O card (Photo B). The card has only two adjustments: brightness and width. The brightness is used to compensate for the camera room lighting. The width is used to adjust the maximum right-hand X coordinate location of picture digitization.

2. *The Fast-Scan TV Display Interface.* This board is one of the most recent additions to the Microworks product line. The board can be used for three unique functions:

- Fast-scan gray-level display interface. (Display has a density of 128 pixels on 128 lines with 16 gray levels.)
- Fast-scan high-resolution graphics display interface. (Display has a density of 256 pixels on 256 lines with two gray levels.)
- Static RAM board, 8K.

Since the purpose of this article is SSTV, the fast-scan gray-level display mode is of the most interest. To display a gray-level picture, all that has to be done is to address the card for any 8K free RAM area and connect the TV display to the appropriate output. The board has two composite video outputs, one for high-resolution graphics, the other for the gray-level display. I found it convenient to mount a switch on the top of the card to switch be-

tween the two modes.

The board functions by allowing the on-board RAM to be refreshed at a video rate continuously. If you wish to read or write to RAM, the video-refresh process is halted for the period of reading or writing while the CPU gains control of the on-board RAM. This has a noticeable effect on your monitor as a small black line called a "sparkle." Otherwise, the picture is flawless, with a quality compatible with any commercial SSTV scan converter.

An experiment which I enjoy is running memory tests on the board. You can see how your memory test is performing. The patterns on the TV display are striking.

To understand how the pixels are formatted in memory, Fig. 2 can be used as a guideline.

You can see that if somehow the picture was placed

in memory, it would automatically be displayed. When you first look at the Microworks board, you will be surprised at the small number of components (Photo C). (This card is not a production model. I include the photo even though it is not representative of the final, professional-looking product.)

3. *The Slow-Scan Television Interface.* The SSTV interface card is the only non-commercially-available interface card that I use in the system. I still use the same card which was described in *73 Magazine*.[2] I would like to redesign the card some day and use more state-of-the-art components.

This card functions by taking a dc voltage proportional to the SSTV frequency, sampling the voltage with an analog-to-digital converter, and then placing the pixel into memory. The SSTV-output inter-

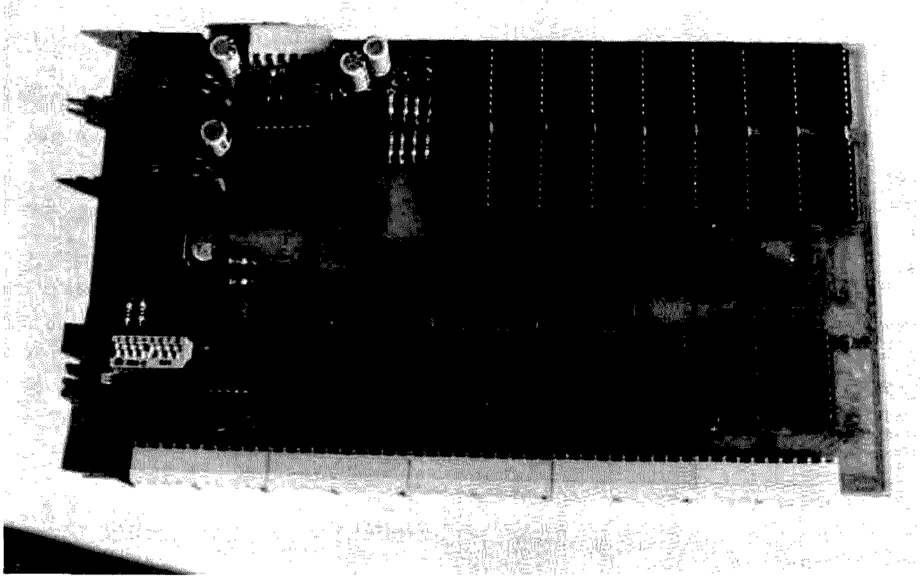

Photo C. Microworks fast-scan display card.

face takes the output from a digital-to-analog converter and feeds it into an SSTV modulator.

4. *The Microprocessor Component*. Remember to treat the microprocessor as just another system component. It can consist of a CPU card, a serial port, and a terminal. (The microprocessor also could be a more complex device such as a single-board computer.) The software which I will present later in this article can provide a software package which could be used for both system configurations.

The Microworks cards which I tested for this article are all SS-50 boards. Therefore, a motherboard must be acquired to plug in the cards if you wish to duplicate my work. The SS-50 bus has been used by a number of manufacturers since 1976. This computer bus structure is a good low-cost approach for system construction. Card costs in most cases tend to be lower than the IEEE-696 (S-100) or Apple bus. The manufacturers and numbers of cards available for this bus are large.

Keyboard Selection	Program Function
F	Transmit the picture displayed on the Microworks display on SSTV. The program will ask for the number of loops desired.
R	Receive SSTV pictures and display them until a key is struck on the keyboard. If a key other than 5 or 6 is struck, the routine will end. If the key is a 5, 50-Hz SSTV will be received. If the key is a 6, 60-Hz SSTV will be received.
C	Capture a TV image from the Microworks Digisector Card. The image is displayed on the Microworks Fast-Scan Display card.
ESC	Jump to TSC FLEX 9 DOS warm start.
Backspace	Jump to Radio Shack BASIC cold start.

Fig. 3.

Program Constant	Function
VIDEO	Picture RAM start of upper right-hand corner
Pixels/line	Constant #111 loaded in RECFST
FRE60	60-Hz delay constant
FRE50	50-Hz delay constant

Fig. 4.

Another approach to interface the Microworks cards is to use a single-board-computer component which can attach to the SS-50 bus. An exciting product which will be very popular in the 1980s is the Radio Shack Color Computer. This computer was introduced in late 1980 and is the first commercial single-board computer which uses the Motorola 6809 processor. The 6809 is a very advanced processor which provides compute power which exceeds that of any of the existing 8-bit processors now available.

One of the interesting features of the color computer is the ease of interfacing. An adapter could be constructed between the side game cartridge connector and the SS-50 bus. Pins on the cartridge connector go directly to the 6809 CPU chip. All that has to be done is to add buffers on a small prototype card. Run short wires to the SS-50 bus. You can then add the Microworks cards and you have a working SSTV system.

I understand that a manufacturer will soon offer such a SS-50 adapter. For those of you who wish to construct your own adapter, Table 1 is provided. This gives a detailed description of each pin on the Radio Shack computer and the equivalent pin on the SS-50 bus.

You may ask if it is possible to adapt older Z80-based Radio Shack computers to the SS-50 bus. It is possible, but probably would take a significant effort. Since the color computer is so cost-competitive, it would be considerably easier to obtain one than to spend the time and effort adapting an older-generation Z80-based machine.

The Software

To glue all the pieces together, what is needed is a software package. The program is a software package which makes a complete SSTV system. It is written to run on either an SWTP 6809-type system or a Radio Shack color computer. The package is less than 1K in size and is written to be position-independent. This feature is available only with the 6809 processor. This means that you can key the program into any place you like in your RAM memory and it will run.

Since the program is well commented, I will not provide flowcharts but will discuss the programming of the Microworks cards in some depth.

Systems Programming. At the start of the program is a listing of program equates and constants. The program assumes that the following is the configuration of the SS-50 cards:

Photo D. SSTV picture via amateur radio—live shot of WB3APB on 10 meters, December 22, 1980.

TRS-80C Pin	Name	SS-50 Pin
1	−12 volts	(note 1)
2	+12 volts	(note 1)
3	Not HLT	45
4	NMI	35
5	Reset	42
6	E	39(phase 2)
7	Q	(note 2) 40 (VMA)
8	Rom init	none
9	+5	(note 1)

11	D1	2(note 3)
12	D2	3(note 3)
13	D3	4(note 3)
14	D4	5(note 3)
15	D5	6(note 3)
16	D6	7(note 3)
17	D7	8(note 3)
18	R/$\overline{W}$	41
19	A0	24
20	A1	23
21	A2	22
22	A3	21
23	A4	20
24	A5	19
25	A6	18
26	A7	17
27	A8	16
28	A9	15
29	A10	14
30	A11	13
31	A12	12
32	Select $C000-FF00	none
33	Gnd	25,26,27
34	Gnd	25,26,27
35	Audio input	none
36	Select $FF40-FF5F	none
37	A13	11
38	A14	10
39	A15	9
40	Disable BASIC ROM	none

Notes: 1. All SS-50 bus voltage must be developed on the bus.
2. VMA is developed by ANDing E and Q.
3. Data lines must be inverted on the SS-50 bus.

Table 1. Radio Shack Color Computer pinout vs. SS-50 bus.

Digisector base address	—$E000
Serial terminal	—$E004
Fast-scan display RAM	—$8000
SSTV interface	—$E010

The object code can be patched to accommodate any configuration you have. If you are using a Radio Shack color computer, the byte labeled RS should be changed to a $FF. With this change, all communications messages to and from program are routed through the BASIC ROM. One other change should be made with the Radio Shack computer. The base address of $8000 is in conflict with the extended BASIC ROM. If this is changed to $6000, the computer should be happy.

You may ask, how do I load this program into my Radio Shack computer? Well, Microworks can help out again. They can provide a monitor program called "CBUG" which will load from audio cassette tape or run in a single 2716 EPROM. The 2716 will plug directly in the Radio Shack computer in the extended BASIC ROM socket. You then will have a program in which you can use machine-language programming to load/save from the built-in audio cassette interface.

Eight bytes of program delays are placed as constants at the beginning of the program. These delays were empirically derived on my home-brew 6809 system with a 1-MHz cycle time. The Radio Shack computer operates at a 0.8949-MHz rate; therefore, all constants have to be increased slightly.

Eight program variables are defined with equates of minus numbers at the program start. These variables can be located anywhere in the memory space. Their location is defined by the location of the system stack when the SSTV program was executed. The system stack is transferred to the user stack and then decremented by 20. All references to these variables are made referenced to the user stack. This is a common programming technique which is used on advanced processors like the 6809 for program-position independence. The user stack is left at this location throughout program execution.

Main Line Software. After initialization of the user and system stacks, the START program is executed. This routine displays a menu on the terminal or TV set in the case of the Radio Shack computer. Five program options are possible, as shown in Fig. 3.

Receive Software. The receive software is very similar to two previously published articles.[2,3] Therefore, I will not discuss the basic principles in this article. One major difference between this program and the others is the formatting of pixels in memory. The memory in this case is the fast-scan display card.

A problem exists with all SSTV display systems—aspect ratio. SSTV has an aspect ratio of 1:1 where a normal TV is 4:3. Another factor which must be addressed is the type of TV which you are using. Some displays underscan the picture while others overscan slightly. In this software package, I chose to slightly overscan the SSTV picture on both the right- and left-hand borders. On the vertical, I decided to lose about 8 scan lines off the bottom of the picture. This appeared to be a satisfactory compromise. A typical SSTV picture received via ham radio appears in Photo D.

You may have to modify slightly the video-scan area to achieve optimum results. This is accomplished by modifying program constants in the areas listed in Fig. 4.

Photo E. TV camera picture displayed on the fast-scan card.

The only other difference in the receive routine from others published is the keyboard polling routine. During a vertical and horizontal sync pulse, the keyboard is polled to see if the keyboard has been struck. If so, the program is ended or a new program delay selected.

Transmit Software. The transmit SSTV picture software is similar to the same two referenced articles. The only major difference is in how the picture is accessed from memory. The picture in the conventional sense is rotated in memory by 90 degrees. This transmit routine accesses bytes from memory in a manner to rotate the picture and transmit it in a correct format.

Camera Software. The software to capture an SSTV picture from the Digisector card was a fun routine to write. The software is extemely time-dependent and functions as follows.

The CAMER routine grabs a picture from the TV camera in a format of 85 pixels/line on 128 lines with 16 gray levels. Why such a strange format? Well, the entire format is based upon a number of compromises of picture appearance, ease of programming, and aspect ratio. The Digisector card is great in that any type of format can be digitized from 256 pixels on 256 lines, with 64 gray levels. You can modify the format to any configuration you like by slight program changes.

Back to the Programming

What I tried to accomplish in this program was to:

- Display the entire camera frame on the fast-scan TV display.
- Make the aspect ratio as accurate as possible on the display.
- Place a black border around the picture to block out any unwanted garbage.

Photo E is a result of the programming. I might add that the lighting and the quality of my TV camera is not the greatest. In any case, you can get an idea of how it looks.

The Digisector is first initialized with the starting X and Y coordinate position in the picture. The program then waits for a response from the card. When the analog-to-digital conversion is completed, the gray level is loaded in the accumulator, formatted, and saved in a constant called FAST. This entire operation must be completed within 2 scan lines or 128 microseconds. The routine in this program takes about 56 cycles or 56 microseconds on my 1-MHz clock processor. The process is then repeated for the next pixel. This time the pixel is ORed with FAST and saved in the video RAM.

The whole process takes about 2 seconds. I was a little concerned with the grab time at first, but I found it quite easy to sit still for 2 seconds while the picture was digitized. Therefore, this condition did not present a problem.

The formatting of the picture may vary depending on the TV camera, the width setting of the Digisector, and the TV display. If you wish to change the aspect ratio for 128 pixels/line, change the $03 at location $127D to $02. You may have to adjust the constant VIDEO1 to a lower value.

Conclusions

The use of the Microworks cards to create an SSTV system is an excellent choice. Unlike the hardware-only SSTV scan converters, the cards and software approach make a versatile and expandable system. Routines can be written to create a software-only SSTV keyboard which mixes graphics and pictures. Picture enhancements can be programmed to achieve many interesting effects. You are limited only by your programming skills and time.

I would like to thank Bob Lentz of Microworks for his help in this project.

If you decide to drop me a line to ask any specific questions, please include an SASE or IRCs for my reply. ■

Cushcraft's Skywalkers

—performance through computer-aided design

Last summer, during what has become the annual antenna renewal at W2NSD/1, a pair of four-element Cushcraft "Skywalker" monoband beams for 10 and 20 meters was added to the antenna farm. Named for *Star Wars* hero Luke Skywalker, they are but two of the six members of Cushcraft's HF monoband family, a family which includes three- and four-element versions for 10, 15, and 20 meters. Like that other Skywalker, these antennas have had a helping hand from computers, being among the first Cushcraft antennas to be designed with the aid of a new computer program.

The Dry Statistics

Cushcraft rates the forward gain of the four-element Skywalkers at 10 dB and that of their three-element relatives at 8 dB. Front-to-back ratio is 30 dB or better for all six antennas.

The 3-dB beamwidth of the Skywalker line averages about 58°. In practical terms, this means that your beam heading can be in error by half that amount, or as much as 29°, and your signal at the other end of the circuit will be down by just 3 dB. That's only half an S-unit, which all goes to show that pointing one's beam with micrometer precision probably isn't worth the trouble.

Monobanders are surprisingly light in weight, for those of us used to triband beams. The four-element 10-meter Skywalker weighs in at a paltry 18 pounds. Even the big 20-meter version tips the scales at only 55 pounds, despite its rugged construction. Wind loadings are 3.1 and 8.1 square feet, respectively. The boom of the 10-meter beam is 16 feet long, while the four elements of the 20-meter Skywalker reside on a boom 32'8" long.

Computer-Assisted Design

The Skywalkers share a common heritage in that all six antennas are the product of computer-assisted design (CAD), using a complex FORTRAN program running on a large IBM computer. With this program, an antenna designer can perform a complete analysis of a projected antenna. The program generates an accurate prediction of the performance of each new design. If an antenna looks good in the computer analysis, a prototype can then be built and subjected to real-life testing.

The advantages of CAD are several. First, considerable research and development time is saved, since a designer using the computer can analyze many potential antenna designs in a short period of time. Unproductive avenues of research can be quickly eliminated from further consideration. With the computer to do much of the tedious work, the designer can spend his time doing what's most valuable—coming up with ideas for better antennas.

Since the computer program makes it easier to check out different designs, it is more likely that unusual or unorthodox configurations will be evaluated. The four-element Skywalkers are direct beneficiaries of this. The computer program figured very significantly in the placement and dimensions of the second director. This particular combination of length and placement very likely would not have been suggested had it not been for the availability of computer analysis.

By the way, if you were thinking it might be fun to run this program on your friendly neighborhood microcomputer, think again. The program is a monster and requires the large amounts of on-line memory available only on large systems.

Assembly and Installation

Although monobanders are usually sold on the basis of their performance, the Skywalkers could be marketed on their ease of assembly alone. One reasonably bright ham can take the four-element 10-meter Skywalker from box to tower in less than two hours. Assembly itself takes less than 90 minutes. The 20-meter version, being twice as large, is more easily assembled with the aid of a helper. Still, the two of you will be able to do the job in a couple of hours.

One firm in our hobby, Heath Company, is famous for its wonderfully complete instruction manuals. Cushcraft has gone them one better, at least in a sense. The Skywalkers are so easy to assemble, you hardly even need the manual at all! Since the boom and the elements are all composed of several sections of telescoping tubing, Cushcraft has sim-

ply marked each piece with a black line to indicate how far it should be inserted into the tubing of the next largest size. You merely insert each piece as far as the black line, tighten the hose clamps, and you have yourself a monoband beam that is resonant at the bottom end of the phone band. Should you wish to be resonant in some other portion of the band, you'll need to adjust the length of the tips of the elements per a table supplied in the manual.

The antenna is matched to the feedline by something called a Reddi Match. This is Cushcraft's name for its variant of the classic gamma match. Here again, adjustment couldn't be simpler. The manual gives the proper position of a sliding bar on the matching unit. If you set this bar to the recommended dimension, a low swr is practically ensured. In the W2NSD/1 installation, this measurement to set the Reddi Match was the *only* measurement required in the assembly of either the 10- or 20-meter four-element Skywalkers.

Cushcraft recommends that antennas of similar size be mounted at least half-a-boom-length above or below a Skywalker when it is stacked with other antennas on the same boom. We initially tried a tribander just six feet above the 20-meter Skywalker, but neither antenna performed well. When the tribander was replaced with the 10-meter Skywalker, both Skywalkers came on like gangbusters.

Both antennas have just endured one of the windiest winters in recent memory, without serious problems. After a very heavy late-February snowstorm, the reflector of the 20-meter antenna was pulled askew by snow and ice accumulating at one end. This was caused by a loose hose clamp on one section of the boom. The problem turns out to be rather common with the Skywalkers, but, fortunately, there is an extremely simple, yet permanent fix. You can drill a small hole through both layers of tubing near the end of each boom section, then insert a 1/2" sheet metal screw. The screw ensures perfect alignment of the boom sections, but is easily removed if the antenna must be disassembled.

Performance vs. Cost

There is little argument that a set of monobanders will outperform a tribander, but what about the cost? Are monobanders really affordable? Well, consider this. For less than $90 above the cost of Cushcraft's ATB-34 tribander, you could own three-element Skywalkers for 10, 15, and 20 meters. Granted, you might need a heftier rotator to turn the three monobanders, but the point is that monobanders don't have to be outrageously expensive.

Should everyone go for monoband beams, then? Of course not. A triband beam is less expensive, easier to install, and probably will require less maintenance than three monobanders. However, when and if you become attracted to the competitive aspects of ham radio, monobanders may be in your future. When you get the urge, the Skywalkers from Cushcraft are a good bet.

Avanti's 10-Meter Quad

It was my intent to have an outstanding signal on 10 meters with a small and light antenna before the band went to sleep for the next couple of years. My present 10-meter yagi loaded well but performed like a dummy load. The yagi was interlaced on a 21-foot boom with 4 elements on 15 meters. The 15-meter yagi was an excellent performer, but the 10-meter antenna just didn't do the job. Below this setup was a 5-element monobander for 20 meters. Obviously, there was not much room for another supersized yagi.

For the past couple of years I had been hearing good things from the 11-meter boys about the PDL II by Avanti Communications. Many stations on the CB band were using this quad-like antenna because they could easily switch from horizontal polarization to vertical or vice versa. Contacts were much more solid because of this unusual ability. It was noticed that as band conditions shifted and signal polarity changed from vertical to horizontal, the PDL maintained transmitting and receiving capabilities.

With all this in mind, I went to see my local amateur radio dealer and asked if he had one of those Avanti PDLs on the shelf. To my surprise, he had a 10m one ready to go. The 10- and 11-meter antennas are identical except for minor changes on the element wires and the gamma match dimensions.

That evening, I read through the Avanti manual to familiarize myself with the materials and construction of the PDL. There were lots of instructions and illustrations, and many parts. The actual assembly went rather quickly; in fact, before I realized what had happened, the whole superstructure was almost completely assembled before me. Part of the antenna had to be disassembled before I could get it through the

back door to the yard.

Once out in the yard, I put the pieces back together and began measuring the copper wire for the two quad loops. The wire elements mounted easily and the tension on each side was adjustable. For the first time since I have been building quads (22 years), the loops were beautifully symmetrical.

The only detail which proved to be tricky was adjusting the antenna for lowest swr. I tried to match the vertical and horizontal to the same point of resonance as well as the lowest swr. Maybe I didn't have to go through all the exercise of standing on the picnic table with the PDL, but I felt it might make my signal a bit better.

With the antenna mounted at 65 feet, swr was almost the same as when it was tested on the ground. The highest swr was 1.9:1 and the lowest was 1.2:1 between 28.550 and 28.700. The highest swr in the entire band from 28.0 to 29.6 was only 1.9:1, which is quite unusual. I was very pleased that the PDL resonated exactly where it is supposed to.

The Avanti 10-meter PDL uses quality materials, although it's my normal practice to replace any stock hardware with stainless. The construction details and illustrations were quite adequate. Actual on-the-air tests prove I now have a performer. The Avanti consistently gets through. In a recent test with my neighbor Al K3BVC, comparing his 3-element tribander with my PDL, a PY2 gave me 59+10 and Al a 57. Most Japanese called are now answering my first call, and that's not easy from the east coast! I have also received reports of 10-dB increases when switching from vertical or horizontal feed on the PDL. It is a good feeling to know that I have selected a performer instead of the dummy load that used to be up there!

VoCom's Collapsible Whip for HTs

—5/8-wave from 144 to 450 MHz

Handie-talkies (HTs) are great fun, but their low power output and typically inefficient rubber ducky antennas limit their range and effectiveness. There are basically three ways to increase range: (1) stand on a hill or other unobstructed location; (2) add a power amplifier; or (3) hook up the unit to a more efficient antenna.

The first solution is fine if you can always manage to operate from a good location, but unrealistic for on-the-go HT work. The second will do the trick, but you end up converting your portable hand-held to a *semi*-portable when bulky externals are added. The third seems to hold the most promise and is much easier and less expensive to accomplish than adding an external amp to your HT.

Adding a *quarter-wave* whip to an HT is no big deal and usually entails cutting a length of small-diameter stainless steel rod stock to about 19" and slapping it into an appropriate connector. The problem, if any, that ensues is a mechanical one—that of finding a way to secure the rod stock in a small BNC, PL-259, or F-type connector.

Harnessing a *5/8-wave* whip to an HT is another story. A base-matching network is required to ensure that the transceiver "sees" a 50-Ohm load. Doing this presents problems, both electrical and mechanical, since the whip must be fastened to the matching coil, and the coil must in turn be mounted to the connector. Several designs have been suggested in the amateur literature, but most require some fancy machining or else result in mechanically inferior "Rube Goldberg"-like products. Another problem is that of tuning and matching: How does one insert an swr bridge at the base of the antenna without seriously affecting the measurements? In most cases, one *doesn't*; he or she cuts the antenna and builds the matching network as closely as possible to spec as he can, hoping that any mismatch will not be serious enough to damage the HT's final rf output transistors or trip the swr protection circuit.

Having wrestled with these kinds of problems before, I was attracted to VoCom's ready-to-go 5/8-wave HT antenna, the ads for which claimed that the device was "...just like adding a 10-Watt amp to your 2-meter hand-held." I sent for one and found the product that arrived to be a very good one.

The VoCom antenna, which was shipped via UPS in a small cardboard mailing tube, is a 10-section collapsible whip, somewhat similar to those found on CB handie-talkies and portable AM-FM radios, but of heavier design. The antenna, designed to permit extension to a full 5/8-wavelength (47") on 2 meters, collapses to 8"— about the same length as a rubber ducky. A pretuned matching network is included, and the base spring/tuned coil protects the whip and radio from various "accidents." At present, the antenna is offered only with a BNC connector, but the firm is working to overcome the mechanical problems associated with using other connectors. Claimed swr is better than 1.5:1 over the

entire 144-148-MHz band. (The HT should not be operated with the antenna collapsed, as the whip would no longer be resonant and an excessive swr would be presented to the HT. This could cause damage to the rf output transistor(s).)

As furnished, at full extended length the whip is designed for optimum performance on 2 meters. However, the antenna will resonate at any frequency from about 143 MHz to 450 MHz simply by changing the length of the collapsible whip. The company has produced a chart of the required resonant lengths for various frequencies, which is available on request.

Wondering just how the very good swr figures reported were measured, I contacted the manufacturer. Fred Glenn K9SO, president, advised that VoCom uses production test fixtures the same approximate size and shape as amateur hand-held radios. These test fixtures are fed through Bird wattmeters to determine the resonant point and swr. Fred also advised that a fairly good approximation of resonance could be obtained by mounting the antenna directly to a wattmeter/swr bridge as long as other objects were kept at least one-half wavelength from the radiating portion of the antenna to avoid distortion in the measurements.

Obviously, using an HT-mounted antenna of any kind results in less-than-perfect ground-plane effects. These effects markedly influence antenna pattern and thus overall results—as much or more so than do matching considerations. VoCom found that the HT itself and the operator's body capacitance provide an adequate ground plane for the 5/8-wave antenna; an ideal ground plane would yield optimal results. Nevertheless, the firm reports tests which measured a 5.6-dB improvement over the standard quarter-wave HT-mounted whip, and a nearly 10-dB improvement over the common rubber ducky.

In evaluating the little antenna's on-the-air performance, I immediately noticed the difference between it and the stock ducky. Tested under a variety of conditions, repeaters that were marginally readable at my QTH on the ducky were very nearly full-quieting, and it was frequently possible to access machines that were unusable before because of inadequate signal from the HT.

Partially extended VoCom 5/8-wave 2-meter HT antenna is shown here installed atop an Icom IC-2AT transceiver. Ten-section antenna is base-matched and boasts a 5.6-dB gain over a 1/4-wavelength whip and as much as a 10-dB improvement over stock rubber ducky antennas, according to the manufacturer's measurements. (Photo courtesy of VoCom Products Corp.)

All things considered, at $24.95, supported by a 1-year warranty, the antenna is a very nice range-extending accessory to have.

HAM HELP

I am in need of a schematic for a Dumont 224A oscilloscope of World War II vintage. I will gladly pay.

Gordon Fulp
Rte. 3, Box 572A
Placerville CA 95667

I'm looking for a schematic for the Edgecom FMS-25. Thanks.

Mark M. Maddox KL7IWT
Rte. 3, Box 46
Rapid City SD 57701

After several years of trying to complete my collection of *73 Magazine* through scrounging at hamfests and trying to keep up a subscription through years of military service, I need help for the final few issues. I desperately need the January, February, March, and April 1961 and November 1960 issues to complete my private collection! I have many extra issues between 1965 and 1974 to swap or sell at 50¢ each. I also need a power transformer for a Heath HO-10 monitor scope.

Bill Ward W4PCK
5521 Ashwood Drive
Anniston AL 36201

I need diagrams for the following: GBC Electronics (Japan) type VR-621 and Packard Bell Model 920 "Sync-Lok" TV cameras; Precision Aparatus Co. series 858 VOM; Jackson Electronic Model TVG-2 TV sweep generator; G.E. "Accent 450" mobile model EU-EG48ST8. I will pay reasonable fee and postage.

Joel Jones W4JQB/7
PO Box 745
Airway Heights WA 99001

I need manuals and/or schematics for the following pieces of equipment. Copy yours and return or state price: Aerovox Model 97 LC checker; Precise Development Corp. oscilloscope, Model 300; Anadex Counter, Model CF-203-4R; ME-74/U electronic voltmeter type RUQ; VHF-AM receiver (Collins); Chadwick Helmuth sweep sync, Model 201R.

Anthony T. Lux KC4MI
1421 Eastern Avenue
Rocky Mount NC 27801

I am a high school Spanish teacher and a General class ham. In order to improve my operating skills in Spanish, I am searching for technical and practical materials written in Spanish. Could anyone provide me with a source of such materials?

Patricia Knasinski WD9FQA
Winchester Community High School
700 North Union St.
Winchester IN 47394

I need a schematic and/or manual for a Hallicrafters S-38E. I'll pay copying and mailing costs.

Paul Grupp KA1LR
RFD
Marlborough NH 03455

I have a Sears and Roebuck CB radio, model 934 36772600, which I would like to convert to 10 meters. This is an ac/dc 23-channel SSB rig. I would appreciate any info on converting this rig. Thank you.

D.L. Hecox WA7IRT
6517 Brookview Lane N.E.
Cedar Rapids IA 52402

I need service info/diagram on Collins KWS-1 transmitter. Will pay reasonable cost for info, copies, etc.

Harold D. Wright K4MFN
Rte. 1, Box 259
Chancellor AZ 36316

Just a note to say thanks to all of you at *73 Magazine* for placing my request for Ham Help in your January, 1981, issue. I quickly received many offers of help and obtained the manuals and schematics I needed. It's this kind of service provided by your magazine and the friendship of those who responded that makes our hobby so enjoyable. Thanks for a great magazine, keep up the good work.

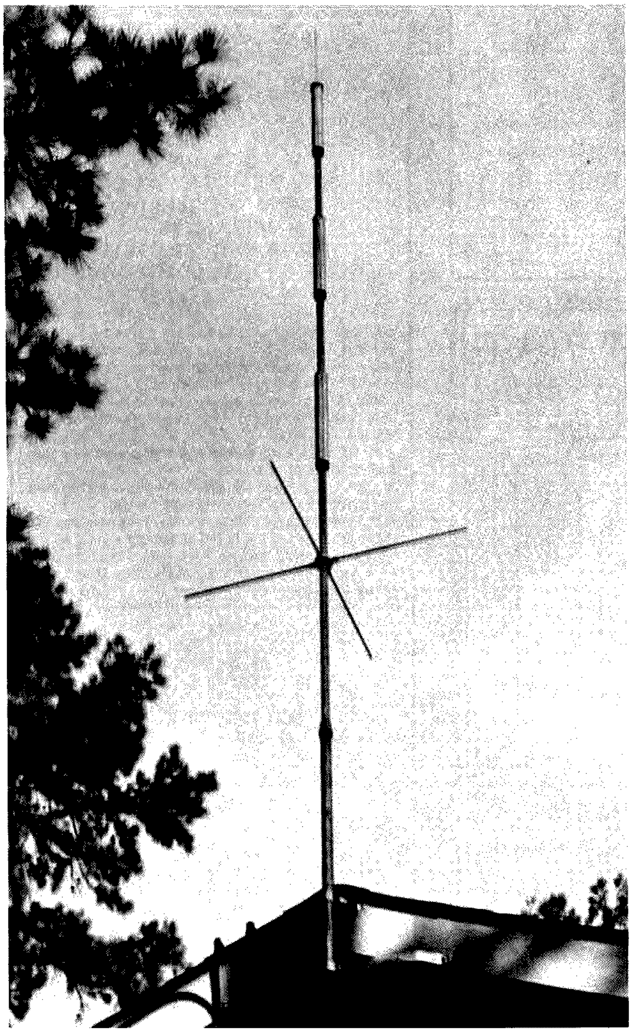
Kreco's SC-150A 2-Meter Collinear

—a commercial-quality antenna built to take it



Kreco four-element collinear antenna gives an approximate 6-dB gain on 2 meters. A quarter-wave radiator, three quarter-wave sleeves, and a ground-plane section constitute the antenna's main components.

In the infancy of this writer's amateur radio experience, back in the seemingly prehistoric 1950s, heavy, massive "plumber's delight" beams were all the rage. Indeed, you were "in" if your tower sported an array that appeared to be crafted by no less than a master plumber. I was, therefore, fondly reminded of the "good old days" by recent ads showing the line of VHF antennas sold by the Herb Kreckman Company of Cresco PA.

The Kreckman catalog displays a line of antennas for the ranges 25-50 MHz, 72-75 MHz, and 108-470 MHz that is geared for the commercial FM two-way trade. Most of the firm's sales are to installers for taxicab fleets, police and fire departments, government agencies, paging services, and related applications. For obvious reasons, the antennas furnished these users must be rugged, maintenance-free, and require little or no tune-up or other installation adjustments.

Most of the Kreco antennas are not particularly useful to hams, and they tend to the expensive side due to their exceptional rugged ness. However, I was intrigued by one particular stacked VHF antenna in the catalog, the SC-150, which is a four-element vertical collinear delivering a stated gain of about 6 dB. It can be factory-set to any frequency within the range 108 to 174 MHz, which includes the two-meter band.

Three versions of the antenna are available, with varying degrees of ruggedness. The relatively lightweight (3-1/2 lbs.) SC-150A is built of aluminum and requires a threaded 3/4" support pipe. The intermediate-duty SC-151A is similar electrically, but is made of slightly heavier materials and weighs 4 lbs.; 1" pipe is required for the supporting mast. A third and extremely durable version is the SC-155, which weighs 4-1/2 lbs. and requires a 1-1/4" support pipe. Several brass versions are available for premium installations. (Weights given do not include the weight of the user-furnished supporting pipe.)

I opted for the SC-150A, the lightweight aluminum version, which I thought would be equivalent in construction to typical amateur-grade VHF antennas, and also in the same price category (cost of the SC-150A is about $66). I or-

dered the antenna factory-cut for 146.5 MHz.

After assembling the antenna (which is UPS shippable) and mounting it on a length of 3/4" pipe, I found that I now had a plumber's delight of my own (the pipe forms an integral part of the antenna). The radiator itself is a quarter-wavelength of sturdy aluminum rod, which is supported by a special ceramic insulator into which the user-supplied pipe threads, along with the PL-259 connector for the feedline, which runs down the pipe. A quarter-wave sleeve drops down over the pipe at this point, forming a coaxial antenna. Two more coaxial quarter-wave sleeves are used for decoupling and gain-enhancing purposes at appropriate intervals down the mast, and a ring supporting the four quarter-wavelength radials is located at a point down the mast which is six quarter-waves (or 1-1/2 wavelengths) from the feedpoint.

The antenna performed well, when compared with my Cushcraft Ringo Ranger. Gain claims were not verified, but seemed to be reasonable, and the antenna offered a good match to RG-8/U coax. Particularly impressive was the antenna's obvious physical strength. Though living in a relatively benign climate, I can picture this antenna much more than some defying the elements at a mountaintop repeater or remote base location.

In trying to be objective, I should emphasize the fact that the antenna must be mounted on pipe. Regular galvanized types are fine, but stay away from aluminum or steel TV mast sections. The antenna feedpoint insulator assembly is threaded for 3/4" pipe, and it will not accept an unthreaded TV mast. Also, the antenna's coaxial sleeve sections are designed around the pipe o.d. (outside diameter), which affects the resonance of the cavity between the skirt i.d. (inside diameter) and the pipe o.d. I purchased and had threaded a 12-foot length of 3/4" pipe (the minimum required), plus an adapter to 1" pipe and a 3-foot section of 1" pipe used to attach the assembly to a standard TV-type eave mount. All this plumbing set me back nearly $18, which added to the total cost of the antenna.

Practically all of the Kreco antennas use the pipe as an integral part of the antenna. Most models are available in aluminum or brass, and each is equipped with a female UHF connector so that a one-piece feedline may be used between the antenna and the transmitter. Type N connectors are also available. Lightning protection is automatically provided by a gap inside the insulator assembly. All models are designed to handle any reasonable power level, being limited only by the power-handling capability of the coaxial transmission line feeding the antenna.

Several particularly interesting antenna designs surface in the Kreco catalog. These include a number of low-VHF band *shunt-fed* coaxial antennas; these boast excellent lightning protection since external surfaces are all at ground potential. A large round cap at the tip of the vertical rods on these antennas conducts electrical discharge down through the pipe and to ground via the tower or supporting structure. Two *folded* ground-plane antennas, one for 25-100 MHz and the other for 108-175 MHz use, are available that offer considerably wider bandwidth than ordinary ground planes; they also afford improved lightning protection by virtue of the grounded radiator element. Several unusual 3-element yagis are also made by Kreco, using folded ground-plane driven elements. Most of the antennas can be retuned to the 6-, 2-, or 1-1/4-meter bands, and some are adaptable for 10 meters.

For the "wideband specialist," for the lack of a more suitable term, the firm also sells a group of commercial discone antennas that boast swrs below 2:1 over an 8-to-1 frequency range. Several models are available, including ones for the ranges 30-240 MHz, 100-800 MHz, and 150-1200 MHz. In these models, the disc and cone are not continuous, but rather are fabricated of 12 radials each. A note in the Kreco catalog advises that the discone antennas can be furnished for various frequencies starting at *4 MHz!*

The company also sells a very modestly priced ($19.95 delivered) 2-meter 1/4λ coaxial antenna, the CO-2A, also designed for pipe mounting. For more information on this antenna, see the "Review" section in the January, 1981, issue of *73*.

All things considered, the SC-150A I evaluated represents a good antenna choice. It's a bit expensive and heavy for the typical amateur installation, but in those instances where ruggedness, durability, dependability, and freedom from maintenance are paramount, it would be a hard choice to beat. For repeater or remote base use, it looks close to ideal.

For more information, write to the *Herb Kreckman Co., Spruce Cabin Road, Cresco PA 18326*. Reader Service number 478. ■

TS-830S *from page 67*

Too low and the noise is not eliminated; too high and audio distortion may occur. Once the happy medium is found, the blanker works quite well on pulse-type noise such as faulty power line transformers and automobile ignitions.

A 20-dB rf attenuator is selectable from the front panel. It becomes useful when you operate the rig in the presence of strong local signals while still hoping to hear the weak ones.

The RIT control has a ±2-kHz range. There is a separate XIT for offsetting the transmitted frequency.

One receiver function leaves me completely cold. This is the Tone control, which is concentric with the VBT knob. To my ears, the audio sounds mushy when the Tone knob is set to any position other than full treble. The manual has almost nothing to say on this control function, causing me to wonder if it was included merely to occupy an otherwise unused control position. I'd like to hear from anyone who has found a use for this control!

The Transmitter

Compared to the receiver, the transmitting portion of the 830S is simple and straightforward. It uses a proven combination of vacuum-tube final amplifiers with solid-state supporting circuitry. The tubes used are a 12BY7 driver and a pair of 6146B finals, both common varieties.

The conventional design of the output stage means that the transmitter must be tuned up, a relatively rare skill these days given the profusion of broadbanded solid-state rigs on the market! Fortunately, a "tune" position on the mode switch allows tune-up to be performed at reduced power, protecting the final

tubes from undue wear and tear. Once learned, tune-up is a 30-second procedure.

The speech processor in the 830S is an rf clipper with two stages, one in the VBT circuit and one in the i-f. A small front-panel knob allows adjustment of the compression level. This setting is rather critical, with about 10 dB of compression on voice peaks being about right. More than 10 dB of compression results in a less-than-pleasing voice quality. Incidentally, when headphones are being used, you can listen to your transmitted audio by pushing the "MONI" switch on the front panel, just to the left of the main tuning dial. I find this indispensable in properly setting the compression level.

VOX controls for gain and delay are also located on the front panel, with anti-VOX on the rear panel. The range of adjustment is wide enough to accommodate almost any microphone you're likely to use with the 830S. A high impedance mike is recommended.

The 830S features semi-break-in operation on CW, with the VOX circuitry and controls performing the task. Hams with electronic keyers should be advised that the 830S employs negative keying, with −65 V at the key jack.

As the 830S is delivered from the factory, the three new WARC bands are enabled only on receive. Getting the rig to transmit on the WARC bands is a relatively simple procedure, requiring the clipping of diodes on the rf circuit board.

The Manual

Kenwood's instruction manual for the 830S contains all of the basic operating information, a small section on maintenance and alignment, and little else. Hams planning to do any serious work on their 830S will be advised to purchase a service manual from Kenwood. The lack of even a rudimentary "Theory of Operation" section in the manual is especially annoying, particularly to anyone attempting to write a review of the rig! The manual does contain a set of small but serviceable schematics, although you may need a magnifying glass to read them.

On the Air

On the theory that competition is an excellent test of machines as well as men, the 830S was pressed into service in the CW section of the 1981 ARRL DX Contest. The rig was operated, mostly on 20 meters, for 48 straight hours. Since our 830S is not equipped with CW filters, we debated whether it should be used at all. We finally decided to try it, cranking the VBT control to the minimum bandwidth of 500 Hz, in an effort to get the selectivity needed for contesting. The results were very gratifying. Not only did the 830S go the whole weekend without missing a beat, but also it turned out to be a fine CW rig even without the accessory filters. I imagine that dyed-in-the-wool CW operators will opt for the crystal filters, but even without them, the 830S does a nice job.

One thing becomes clear after you've operated this rig for a while. That is that Kenwood did some heavy thinking about how best to "human-engineer" the TS-830S. Take the knobs on the front panel, for instance. There are 5 distinctly different shapes and sizes. The result is that your mind quickly becomes attuned to seeking out the "small, flat knob" when selecting a meter function, or looking for the "tall, round knob" when going for the VBT. This difference in physical appearance is coupled with a very thoughtful layout, in which the most-used controls are placed in the most convenient positions. Compared to brand-new radios from other manufacturers, and even compared to the old 820S, the TS-830S gets high marks on human-engineering.

Summary

What we have here is an HF ham rig that is evolutionary, as opposed to being revolutionary. Kenwood obviously wanted to produce a worthy successor to the 820S, and they have done so, with a price tag that is lower than the 820S. The aspects of the 820S that endeared that rig to its admirers have been retained in the 830S, while more modern receiver attributes have been added and the layout of controls improved a great deal. If, in these days of the solid-state avalanche, you still feel more comfortable with a pair of nice, friendly 6146Bs, then Kenwood has a radio for you—the TS-830S. It's destined to become an industry standard.

For further information, contact *Trio-Kenwood Communications, Inc., 111 West Walnut, Compton CA 90220.*■

PCS-3000 *from page 71*

rear). High power is adjusted by VR408 and low power by VR407, both near the center of the board. Auxiliary offset crystals are near the front, and can be "pulled" to move the offset up or down, via adjacent inductors, by as much as 15 kHz.

Performance

Of course, all this microcomputer convenience is great. But how does the unit perform? I connected my new PCS-3000 to a fixed outdoor antenna and wattmeter/swr bridge, and after getting acquainted with the microcomputer, I ran some tests.

My radio, on my particular wattmeter, puts out 27 Watts in high power and 6 Watts in low power with a 1.1:1 swr on the antenna. (The PCS-3000 is swr protected to the point that you can transmit into an open or short circuit; high swr will no doubt result in lower power output, but you don't have to worry about burning out the final amplifier.) The low-power level is internally adjustable by means of a potentiometer, VR407, in the center of the board on top of the main unit, over a range of zero to 25 Watts.

Other stations reported excellent audio quality, without exception. Realizing that folks sometimes tend to be overly courteous, especially when they know you've just bought a new rig, I pressed the issue. I asked them specific questions, such as "Does it sound tinny or bassy? Is there any background noise or distortion on modulation peaks?" Still, nobody had anything bad to say.

Received audio quality was also superior. I connected my own external speaker up to the rig via the 1/8-inch phone plug on the rear of the main unit. I haven't heard a better FM rig.

My PCS-3000 uses five Amperes in high power. My supply delivers six Amperes, so this is no problem. A couple of lantern batteries in series probably won't do it, though.

I also conducted tests for microphonics. While talk-

ing to a friend, I literally pounded on the radio and dropped it from a height of a few inches onto the table (which was protected by a placemat!). In both receive and transmit, there was no detectable noise on the signal, except for the noise in transmit that was picked up by the microphone ("What are you doing to that radio, man?").

Mobile Operation

You'd better get acquainted with the microcomputer before you go out and try to operate this radio while driving. Once you're familiar with it, it's easy and convenient to use; it'll almost operate itself.

Here in Miami, the interior of an automobile can rise to formidable temperatures even in the winter. Would this have any effect on the audio quality? Tests with other stations indicated it didn't, other than to produce intermittent gasps and a rather sleepy sound on the part of the operator.

I made a special point to inquire about alternator whine or ignition noise on the transmitted signal. I've never had any trouble of this kind in the past with previous rigs, so I guess my car is pretty quiet in that respect. There wasn't any of this kind of problem with my PCS-3000. Other stations reported the same excellent audio quality in mobile operation as in fixed operation. What about background-noise pickup? Well, going 55 mph into a stiff breeze with all the windows rolled down and a semi truck passing me, I have to confess that other stations noticed quite a bit of background noise. But I was still "solid copy."

The digital "S"-meter, consisting of five red bar-type LEDs, is very sensitive. A full-quieting signal always lights all five of them. If a signal is so weak that none of them is lighted, it's almost unreadable. (Incidentally, even the weakest of weak signals will stop the scan.) The meter reacts very rapidly to changes in signal strength such as "picket fencing." No mechanical meter could possibly follow this.

In an unfamiliar area, the programmable band-scan feature is very convenient. You may want to scan the entire 2-meter FM band, but it is useless to waste scanning time covering a bunch of frequencies you know won't have any FM signals. I program 145.11, the lowest repeater output frequency in the United States, into memory 7 and 147.39, the highest, into memory 8, before going on long trips. The PCS-3000 scans about five channels per second, which is roughly 25 kHz per second using 5-kHz increments and 50 kHz per second using 10-kHz increments. To cover the above range, the scanner takes one minute and 29 seconds in 5-kHz steps and 44 seconds in 10-kHz steps.

Interesting Quirks

One thing that I discovered, after several hours of operation, is that this radio actually has a hidden memory channel. What's more, it is instantly available at any time, just like the priority channel, memory 1. The PCS-3000 remembers the frequency you're on just before you go into memory mode. When you leave the memory mode, you're back on that frequency.

I usually set my rig to 146.52 before I go into memory mode, so that I can instantly go back to this important simplex frequency. Usually, I have 146.52 programmed into memory 7 as the lower limit of the band scan and don't want to duplicate it in memory 1.

If you program the band-scan limits in backwards—that is, the upper limit in memory 7 and the lower limit in memory 8—the scanner won't work. In this case, as soon as you hit BAND SCAN, the microcomputer will go to memory channel 7 and stay there, blinking just a bit as it scans that one channel over and over!

The "channel lock" switch, located on the microphone and used for monitoring the repeater input frequency, operates by making the microcomputer think the radio is transmitting when it is actually receiving. Since the keyboard is disabled in transmit mode, the channel lock switch also has this effect. You can still transmit on the repeater input frequency when this switch is activated.

It's almost as if this microcomputer radio has its own personality traits. I already feel as if I "know" it!

Specifications

I was able to actually check only a few of the specs on my PCS-3000, and have marked those with an asterisk, in the list of vital statistics given in the literature—see Table 1.

Introductory price for this rig (at the time of this writing) is $339 with the free touchtone pad kit. All accessories such as power cord, fuse, microphone, and mobile mounting bracket/hardware are included. Optional accessories include an external speaker, extra dc cord and plug, extra mobile mounting bracket, 15-foot cable for remote-head operation, 6-Amp ac power supply, and touchtone microphone back kit. The PCS-3000 is distributed by *Amateur-Wholesale Electronics, Inc., 8817 S.W. 129 Terrace, Miami FL 33176;* call toll-free, 1-(800)-327-3102. Reader Service number 479. ■

73 ON THE AIR

THE SCHEDULE

May		June	
5	15m-20m phone	2	15m-20m phone
12	40m-80m CW	9	15m (Novice)-20m CW
19	20m-40m phone	16	40m-80m phone
26	80m-160m phone	23	20m-40m phone
		30	15m-40m phone

Starting this month, W2NSD/1, our station here at *73 Magazine*, will be on the air each Tuesday evening between 8:00 pm and 11:00 pm EDT (0000 and 0300 UTC Wednesday). An operating schedule is provided for May and June.

In order to meet as many of our readers as possible, we will be operating in the General class portion of most bands. You will find us somewhere within the first 25 kHz of each General class segment, so on 20-meter phone look for us between 14.275 and 14.300, on 40 meter CW find us between 7.025 and 7.050, etc. Our Novices and Technicians will be operating in the first 25 kHz of the Novice bands on 80, 40, and 15 meters.

We will be operating on two bands per night, using the higher frequency band for the first half of the operating session and the lower frequency band for the second half of the session.

The operator could be any of our licensed staffers, and don't be surprised if the OM himself answers your call some Tuesday evening.

We are looking forward to speaking with our readers and hope to meet many of you in the coming months. To help you get to know us better, here is a brief look at who we are and what we do at *73*.

Wayne Green W2NSD/1—Wayne is the founder of the 73 *organization. In addition, he publishes two computer magazines (*Kilobaud MICROCOMPUTING *and* 80 Microcomputing*), two industry newsletters, and heads up Instant Software, Inc., a microcomputer software publishing house.*

Wayne's interests include travel, economics, sports cars (a Jaguar XJ6, Datsun 280Z, and Mazda RX-7 owner), gourmet cooking, and technology. He'd enjoy talking about any of these with readers.

Jeff DeTray WB8BTH—Jeff is second in command at 73 *and has a full range of administrative and technical responsibilities. He's known as "The Wizard" around here due to his ability to patch together ham radio and computer projects from a bottomless junk box of LEDs and 741 ICs.*

Jeff, a transplanted midwesterner from Napoleon, Ohio, is the driving force behind the NSD contest effort. Under his tutelage, the station amassed over 1 million points in the phone portion of the 1980 CQ Worldwide DX Contest (multi/single) and 195,000 points and a clean sweep in Phone Sweepstakes (single operator). If you work NSD during a contest, the impatient voice at the other end of the exchange will be Jeff's (unless he's managed to trick some fellow staffers into operating with him).

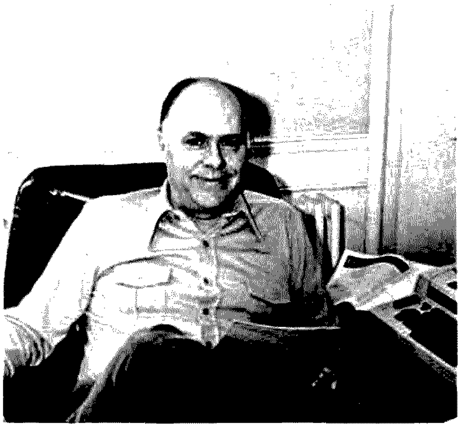
His interests include computers, astronomy, and motorsports (NASCAR, Formula 1, and Indy).

Penny Brooks KA1GAW—Penny, one of our newest Novices, is in advertising space sales for 80 Microcomputing. *She is a Navy veteran with two years of service under her belt who's been known to copy CW at over 30 wpm. Look for her clean fist on the 80, 40, and 15-meter Novice bands, hopefully not at 30 wpm.*

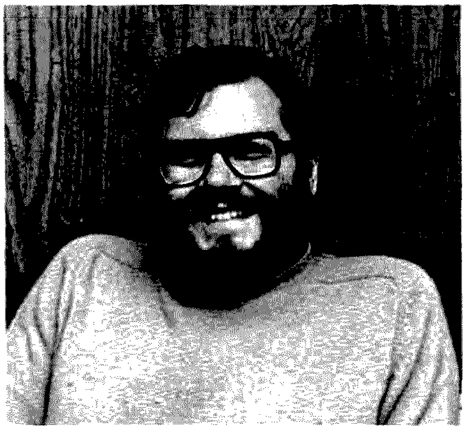
Chris Brown KA1D—Chris is a contributing editor with 73 *and also shares his time with the computer magazines. He handles feature writing assignments and enjoys operating out of the mainstream—160 CW for instance. His interests include running (Boston Marathon survivor), mountaineering, astronomy, and reading. He can often be found on 80 and 40 meters in the still of night.*

Ed Ferman WA1UFY—Ed is our director of publications. He keeps the magazine's printers honest and our editorial and art departments on deadline. He's on his feet so much he doesn't even have a chair in his office.

His outside interests include raising championship Golden Retrievers, gourmet cooking, sailing his 36-foot Choey Lee,

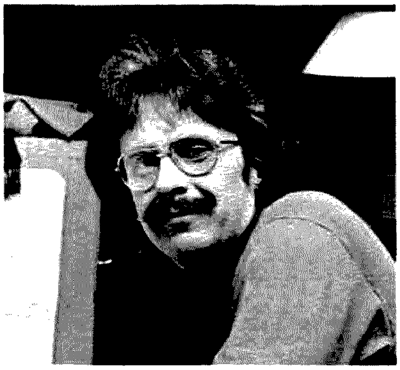


Wayne W2NSD

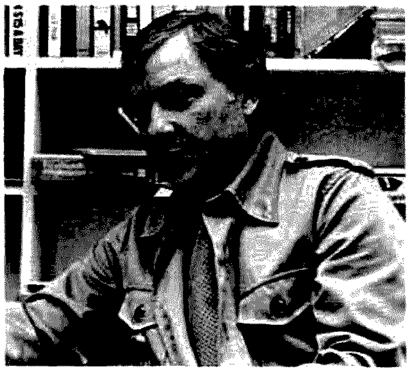


Jeff WB8BTH

Penny KA1GAW



Chris KA1D



Ed WA1UFY

Jim W1XU

Alyson N1BEJ

Paul KA1LR

and blacksmithing. Ed, an Air Force vet with many hours of jet time, plays jazz bass and hopes to have his own haute cuisine restaurant some day.

Jim Gray W1XU—Jim is the Advertising Manager for 73 Magazine. He spends his time on the phone with advertisers past, present, and future trying to convince them of the benefits of four-color versus two.

Jim is a licensed pilot (private/single engine, commercial/glider) and flies whenever he can. He also does a lot of walking in the hills of New Hampshire, rides a motorcycle in all weather, plays tennis, and shoots 35mm photos. Jim has been hamming for 31 years and has a special place in his heart for CW.

Alyson Grupp N1BEJ—Alyson works in our data processing department. She thrives on DX and wants the 73 station to acquire a bigger tower and more monobanders. Aly plans to upgrade to Advanced shortly, without using the Bash book.

She enjoys kit-building and writing, and has penned several reviews for 73. When she's not DXing, Alyson is likely to be canoeing with husband Paul. Together they've paddled most of Minnesota's Boundary Waters hauling ham gear and generators with them.

Paul Grupp KA1LR—Paul is our Product Review Editor. He pores over ham magazines and catalogs looking for likely review prospects and enjoys evaluating new equipment. He is a hopeless DXer and operates phone almost exclusively, pretending that he can't find the CW position on the new rigs that come into the shack.

When he's not building repeaters or chasing DX, Paul enjoys photography, working in his recording studio, and playing his guitars. He was raised in Egypt and hopes to organize a DXpedition to the Mid-East.

Knud Keller KV4GG—Knud, our accounting manager, is the money man at 73. He is the one who ends up with the invoices for the ham shack equipment that the rest of us have ordered. He then tracks down the perpetrator to find out why we have yet another new rig, and how we intend to pay for it. Everyone avoids Knud at invoice time.

Besides being good with figures, Knud is an accomplished musician specializing in strings and keyboards. He's also one of the few licensed piano tuners in New Hampshire and the best Volkswagen mechanic on staff.

Ross Kenyon KA1GAV—Ross is the manager of 73's printing department. He spends his time working on OSL cards and a host of other ASAP projects in the 73 print shop. He is both a new ham and a new daddy, and his Novice ticket arrived at about the same time his new daughter did. His hobbies include fishing, photography, and child rearing. Ross is also a member of the Masons.

Gene Smarte WB6TOV—Gene wears a few hats at 73. He is the News Editor and also the Acquisitions Editor. Gene separates the wheat from the chaff in the newspages and is on the horn with authors when 73 wants to cover a hot topic and needs a story written, pronto.

Gene is a rare bird, a native Californian living in New England. He copes with the puritans in a laid back and mellow manner and, were it not for his collections of weird, flower-print California shirts, we'd almost believe he was a Bostonian by birth.

Gene is interested in beekeeping, astronomy, scrounging flea markets, banjo picking and, by his own admission, California dreamin'. He'd enjoy speaking with sixes.

Tim Daniel N8RK (not shown)—After serving two summer internships with the 73 organization, Tim has finally come on staff full-time. Tim graduated from the Rose-Hulman Institute of Technology in Terre Haute, Indiana, in February with a B.S. degree in Electrical Engineering; he will be in charge of special projects at 73. He has authored our new Novice and General class study guides and enjoys writing almost as much as engineering and design.

Tim is an enthusiastic contester. He operated with Jeff DeTray from Turks and Caicos in March during the ARRL International DX contest under the call VP5TDX.

A transplanted flatlander (Oxford, Ohio), Tim is now getting used to biking up and down New Hampshire's hills and valleys. He also enjoys hiking in the White Mountains, reading, and travel.

Knud KV4GG

Gene WB6TOV

NEW PRODUCTS

Versa Tuner V from MFJ.

SUPER LOG™ II

Whether you're a rag chewer, contester, award hunter, or DX operator, the new Super Log II is the radio operator's ultimate dream come true! Created by MICRO-80 programmer Joe Richey, this "machine language" software is compatible with both the TRS-80 Model I and Model III computer systems.

How many times have you had to search through all your logs trying to find a record of a particular contact made? If you're an award hunter or DX operator, you already know the nightmare of sorting through all those QSOs trying to satisfy various award requirements. If you're a contester, we don't need to remind you of the awesome task of keeping an accurate and legible log to be able to determine if a contact is a duplicate or not. Now you can eliminate all those frustrations and enjoy keeping a log once again.

Super Log II will instantaneously retrieve information about a previous contact with its special "Lightning Search & Sort."

Super Log II initializes popular column headings found in conventional radio operator logbooks: date, beginning and ending QSO times, callsign worked, QTH, RST sent and received, mode and frequency of operation, and a special section is reserved for entering comments relative to the contact made.

For a limited time only, all customers purchasing Super Log II will also receive free from MICRO-80 the very popular amateur radio program Super Duper II. With this program, the operator can keep calls sorted by band or mode. The computer immediately alerts you to duplicate contacts as they occur and allows the option to delete them from the log. Now contesters can eliminate the drudgery that has taken the fun out of their competitive hobby!

Both programs are available now for the price of one.

For further details about MICRO-80 products and services, write *MICRO-80, Inc., S-2665 North Busby Road, Oak Harbor WA 98277.* Reader Service number 489.

NEW MFJ 3-KW TUNER WITH ROLLER INDUCTOR

The new MFJ-989 "Versa Tuner V" uses a roller inductor with a 3-digit turns counter and a spinner knob for precise inductance control to get swr right on down to minimum.

This new tuner has a big 3-kW PEP rating that you won't outgrow and smaller, more compact, size to match the new smaller rigs.

For convenience, the MFJ-989 gives you several products in the same compact cabinet. First of all, it's a 3-kW antenna tuner, roller inductor and all, that matches coax, balanced line, and random wire from 1.8-30 MHz. Second, it's a six-position antenna switch (2 coax lines, through the tuner or direct, random/balanced line, and dummy load). Third, it contains a 300-Watt, 50-Ohm non-inductive dummy load. Fourth, it's a wattmeter using a lighted meter with 2% accuracy (requires 12 volts for lighted meter). This wattmeter reads both forward and reflected power on 2 scales (200 Watts and 2000 Watts), plus it reads swr directly. Finally, it has a built-in 4:1 balun for balanced line.

It's amazing that all these features can fit into such a small package (just 10-3/4" W × 4-1/2" H × 14-7/8" D). The deluxe aluminum low-profile cabinet has a subchassis for RFI protection. It has a black front panel with raised brushed aluminum lettering, and the cabinet has a black finish. There is also a bail to raise the front for easy viewing.

If ordered from MFJ, there is a 30-day money-back trial period. If you are not satisfied, you may return it within 30 days for a full refund (less shipping). MFJ also provides a one-year limited warranty.

For more information, write *MFJ Enterprises, Inc., PO Box 494, Mississippi State MS 39762, or phone toll-free 1-(800)-647-1800.* Reader Service number 487.

CORRECTION

The price for Benjamin Michael Industries' 24-hour clock was incorrectly listed in our March "Review" section. The correct price is $29.95.

COMM-X FROM VALOR

A forerunner in the Valor Enterprise family of new products for 1981 is the "Communications Extender" antenna series. Known as "COMM-X," the series presently includes two models. Model CX-144 is designed for 144-148 MHz and is 52" in length. At 35" in length, the CX-220 model operates in the 220-225 MHz range.

Both models feature adjustable whips designed to allow field tuning for optimum vswr, typically 1.5:1 or less at resonance, and typical gain of 3 dB over a 1/4 wave standard. In addition, two stainless steel set screws secure the heavy-duty whips to provide double-locked protection. The ferrule is attached with adhesive, besides being mechanically staked to ensure integrity.

The COMM-X is power rated at 200 Watts and is made of quality materials. These materials include 17-7 taper-ground stainless steel whip, 16-gauge copper matching coil, and standard 3/8-24 chrome-plated brass base. This combination provides excellent wear resistance for long-lasting service.

Valor Enterprises specializes in communication products. Additional information may be obtained by writing *Valor Enterprises, West Milton OH, or calling (513)-698-4194. Outside Ohio call toll-free 1-(800)-543-2197.* Reader Service number 480.

HUSTLER INTRODUCES NEW TEN-METER YAGI ANTENNA

The new beam from Hustler, designated 10-MB-4, is the conclusion of extensive design refinements of previous beam technology.

The result is a four-element yagi optimized for best directivity, excellent front-to-back ratio, and maximum gain through selective element spacing and precisely resonated element length.

The 10-MB-4 employs a gamma-match feed system and is fully adjustable for a 1.2:1 or better swr at resonance.

The mechanical structure of the Hustler 10-MB-4 is ruggedly designed to withstand severe weather, yet is light enough to be accommodated by a TV antenna rotor.

The entire antenna is constructed from high-strength aluminum tubing and can be easily grounded for lightning protection.

For further information, write *Hustler, Inc., 3275 North B Avenue, Kissimmee FL 32741.*

NEW ZAP TRAPPER™ PROVIDES SUPERIOR PROTECTION FOR ANTENNAS, CABLE, AND COMMUNICATIONS EQUIPMENT

The new Zap Trapper™ (patent pending), introduced by PolyPhaser Corporation, significantly outperforms previous lightning protection apparatus for communications antennas,

cable, and equipment, according to Roger R. Block, PolyPhaser president.

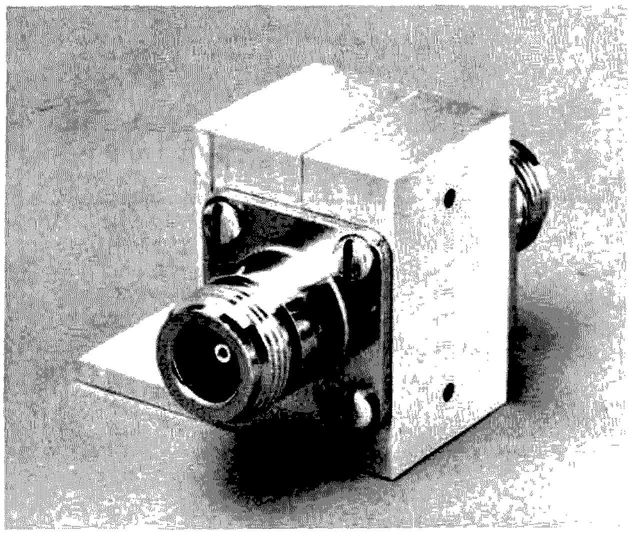
The new Zap Trapper impulse suppressor utilizes controlled atmospheric technology. "This process is field-proven in the telephone industry and ensures a microsecond response to lightning impulses, plus multiple impulse suppression which is especially critical for the protection of today's solid-state communication equipment," Block stated.

"Typical air-gap type arrestors will shunt the first of many impulses within a single strike safely to ground and then become useless due to contact vaporization for the remaining impulses." In effect, Block remarked that "arrestors" or air-gap devices do little more than provide a sense of false security beyond the initial energy impulse.

PolyPhaser's Zap Trapper installs quickly, directly into the transmission feedline, and is available with either type N or UHF connectors.

The Zap Trapper will handle up to 750 Watts of rf power with an insertion loss of 0.1 dB at 1000 MHz. Vswr is less than 1.15 with a constant 50-Ohm impedance. Turn-on voltage is 280 V dc and it will handle a 10,000-Amp surge.

For more information, contact *PolyPhaser Corporation, 1500 West Wind Boulevard, Kissimmee, FL 32741, telephone (305)-846-1807.* Reader Service number 482.

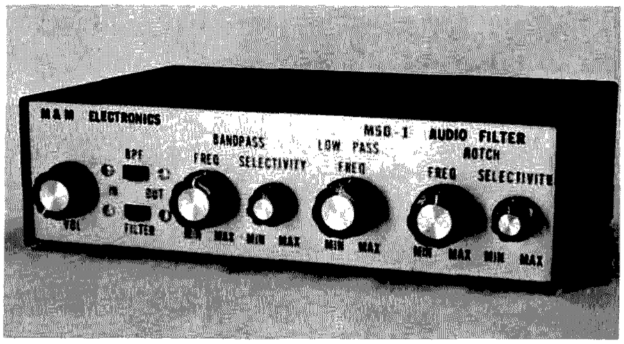


PolyPhaser's Zap Trapper.

MSB-1 AUDIO FILTER FROM M & M

The MSB-1 audio filter from M & M Electronics utilizes four basic filters arranged to provide the maximum in flexibility and effectiveness during SSB, CW, or RTTY reception. The fixed high-pass filter, tunable notch filter, six- and eight-pole tunable low-pass filter are engaged at all times. The tunable bandpass filter can be switched in for further shaping of the audio. This means that all three tunable filters can be engaged at the same time and tuned independently.

For more information, contact *M & M Electronics, PO Box 1206, Brewton AL 36427.* Reader Service number 488.



New audio filter from M & M.

NEW BASE STATION ANTENNA FROM VALOR ENTERPRISES

Joining Valor Enterprises' most recent announcement of the "Omni-Gain" mobile antenna is the "Omni-Gain" base station antenna. Designed to complement its mobile counterpart, the base station antenna features the same unique construction and power rating of 200 Watts.

Made of 17-7 stainless steel whip, 6061-T6 electro-polished aluminum coaxial matching section, and chrome-plated brass 3/8-24 ferrule, the "Omni-Gain" has no copper coil.

The base station antenna is 5/8 wavelength, has a 3-dB gain, and is available for 2-meter and 220-MHz amateur bands. The series is field tunable to a typical vswr of less than 1.5:1 at resonance.

Valor Enterprises is a manufacturer of personal and amateur communication products and accessories. For more information and complete product catalog, write *Valor Enterprises, West Milton OH or call (513)-698-4195; residents outside Ohio dial toll-free 1-(800)-543-2197.* Reader Service number 481.

MFJ INTRODUCES NEW LOW-COST VHF OPERATING AIDS

The new MFJ-812 is a VHF swr/wattmeter/field-strength meter combination. It keeps you informed about your antenna and feedline as well as you rig's output. It reads swr at lower power levels from 14 to 170 MHz, and also reads forward and reflected power from 144 to 148 MHz on two scales (30 and 300 Watts). Easy push-button operation switches from forward to reflected power.

Binding posts are provided on the back panel for easy field-strength antenna connection. The MFJ-812 reads field-strength level from 1 through 170 MHz.

The MFJ-812 measures 4-1/4" W × 2-1/4" H × 2-3/4" D. The all aluminum cabinet has an eggshell white front panel with black top and sides.

MFJ provides a 30-day money-back trial period. If you are not satisfied, you may return it within 30 days for a full refund (less shipping). MFJ also provides a one-year unconditional warranty.

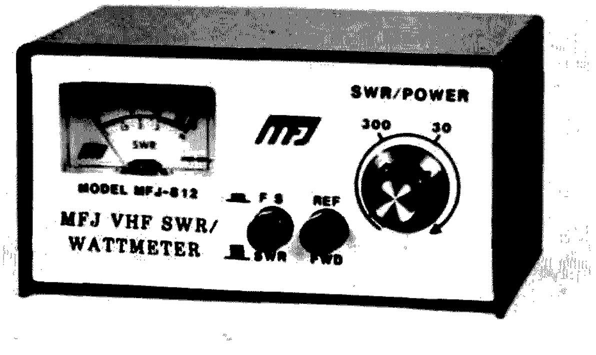
The MFJ-810 is like the MFJ-812, less the field-strength function.

For more information, write *MFJ Enterprises, Inc., PO Box 494, Mississippi State MS 39762, or call toll-free 1-(800)-647-1800.* Reader Service number 486.

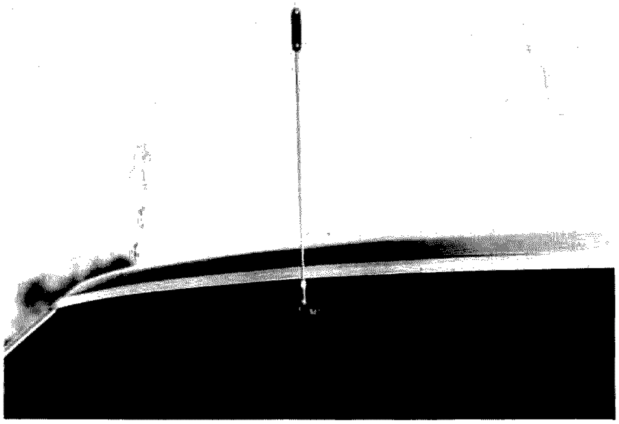
NEW 5 dB-GAIN MOBILE ANTENNA FROM AVANTI

Avanti Communications has recently modified its 5-dB gain on-glass mobile antenna designed for use in two-way and amateur radio communications.

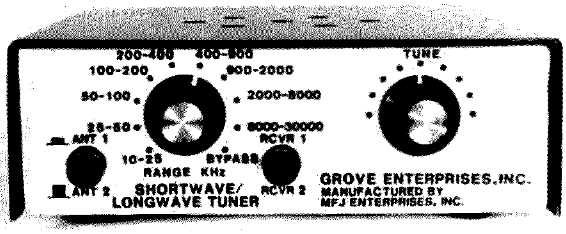
The new 3/4-meter 410-512 MHz AP450.5G features a straight 30-inch whip with a small center-positioned phasing coil. By popular request, the former loop section has been eliminated and replaced by a small, sleek coil measuring only



New swr/wattmeter/field-strength meter from MFJ.



Avanti's AP450.5G antenna.



New tuner from Grove Enterprises.

1-1/2 inches in length and a maximum diameter of 3/8", making it the smallest UHF 5-dB gain whip and phasing coil combination on the market.

As with each of Avanti's on-glass communications antennas, the new AP450.5G offers improved performance, requires no holes to be drilled, features shorter installation time, and requires no metal ground plane, thus allowing it to be used in many more applications than conventional mobile antennas.

For more information, contact *Avanti Communications, 340 Stewart Avenue, Addison IL 60101; phone (312)-628-9350.* Reader Service number 483.

SHORTWAVE/ LONGWAVE TUNER

Designed to enhance reception in the 10-kHz through 30-MHz spectrum, this new shortwave/longwave antenna tuner claims the widest frequency coverage of any tuner on the market.

The wideband tuner preselects desired signals while reducing or elminating intermodulation, crossmodulation, images, and desensitization from unwanted signals.

Front-panel switching allows push-button selection of two antennas and two receivers, while a front tuning dial permits signal enhancement.

The wideband tuner is guaranteed to improve reception on any shortwave or longwave receiver.

For more information, write *Grove Enterprises, Inc., Dept K. Brasstown NC 28902, or call toll-free 1-(800)-438-8155.* Reader Service number 485.

CONTESTS

Robert Baker WB2GFE
15 Windsor Dr.
Atco NJ 08004

COUNTY HUNTERS SSB CONTEST

Contest Periods:

0001 to 0800 GMT May 2
1200 GMT May 2 to 0800 GMT May 3
1200 to 2400 GMT May 3

Please note the two 4-hour rest periods. Mobiles may be worked each time they change counties or bands. Mobiles that are worked again from the same county on a different band count for point credit only. Mobiles that are contacted on a county line count as one contact but 2 multipliers. Fixed stations may be worked by other fixed stations only once during the contest. Repeat QSOs between fixed stations on other bands are not permitted. Fixed stations may be worked by mobiles each time they change counties or bands. Repeat contacts between mobiles are permitted provided that one station is on SSB. Contacts made on net frequencies will not be allowed for scoring in this year's contest.

EXCHANGE:

Signal report, county, and state or country.

FREQUENCIES:

Suggested frequencies are as follows: 3920-3940, 7220-7240, 14275-14295, 21375-21395, 28625-28650. There will be a "mobile window" of 10 kHz on the following frequencies: 3925-3935, 7225-7235, 14280-14290. Mobiles will be in this 10-kHz segment and fixed stations are asked to refrain from calling "CQ Contest" in the mobile window. After working mobiles in the window, fixed stations are requested to QSY outside the window to work fixed stations in the contest. This will allow the mobiles running lower power a chance to be heard and worked in the contest. There will be a special effort to work DX on 28.636 by mobiles.

SCORING:

Contact with a fixed US or Canadian station = 1 point. Contact with a DX station (KL7 and KH6 count as DX) = 5 points. Contact with a mobile station = 15 points. The multiplier is the total number of US counties plus Canadian stations worked. The final score is this multiplier times the total QSO points.

AWARDS:

MARAC plaques to the highest-scoring fixed US or Canadian station, DX station, and top 2 scoring mobile stations. Certificates to the top 10 fixed and mobile stations in the US and Canada and to the highest-scoring station in each DX country.

ENTRIES:

Logs must show date and time, station worked, reports exchanged, county, state, band, claimed QSO points (1, 5, or 15), and each new multiplier must be numbered. Logs and summary sheets are free for a #10 SASE or SAE and appropriate IRCs. Write to: John Ferguson WØQWS, 3820 Stonewall Ct., Independence MO 64055. All entries must be received by June 15th to be eligible for awards. DX entries should use air mail. Winners will be announced at the 1980 Independent County Hunters Convention during July and in the MARAC newsletter.

ALEXANDER VOLTA RTTY DX CONTEST

Starts: 1200 GMT May 2
Ends: 1200 GMT May 3

This is the 16th contest sponsored by the SSB and RTTY Club of Como and the Associazione Radioamatori Italiani. Use all amateur bands from 80 through 10 meters. Operating classes include single operator, multi-operator/single-transmitter, and SWLs. Stations may not be worked more than once on any one band. Additional contacts may be made on different bands.

EXCHANGE:

RST, QSO number, and zone number.

SCORING:

All 2-way RTTY contacts between stations of the same country are not valid. Contacts with stations outside your zone count for points in accordance with an Exchange Points table (available from Associazione Radioamatori Italiani). Any RTTY contacts made on 80 or 10 meters are worth double.

A multiplier is given for every country worked on each band worked. An extra multiplier is given for each intercontinental country worked on at least 4 bands. Use the ARRL Country List and count each USA, Canadian, and Australian district as separate countries.

SWLs use same scoring rules but based on stations and messages copied.

CALENDAR

May 2-3	County Hunters SSB Contest
May 2-3	Alexander Volta RTTY DX Contest
May 9-10	Rocky Mountain Division QSO Party
May 10	DARC Corona—10-Meter RTTY Contest
May 16	Dogwood Festival QSO Party
May 16-17	Florida QSO Party
May 16-18	Michigan QSO Party
May 16-18	Massachusetts QSO Party
May 23-24	Europe and Africa Giant RTTY Flash
Jun 6-7	VK/ZL/Oceania RTTY DX Contest
Jun 6-7	New York State QSO Party
Aug 8-9	European DX Contest—CW
Aug 15-16	SARTG Worldwide RTTY Contest
Aug 22-23	Ohio QSO Party
Sep 12-13	European DX Contest—Phone
Sep 12-13	G-QRP-Club CW Activity Weekend
Sep 12-14	Washington State QSO Party
Sep 26	DARC CORONA—10-meter RTTY Contest
Nov 8	DARC CORONA—10-meter RTTY Contest
Nov 8	OK DX Contest
Nov 14-15	European DX Contest—RTTY
Dec 26-31	G-QRP-Club Winter Sports

RESULTS

3rd DARC CORONA CONTEST

These are results of the 3rd DARC Carona Contest held on 27th September, 1980. Congratulations to N8ES for a really convincing win, and to G3HJC for being top "G".

Call	Score	GSO	Countries	Prefix

2. Werner Ludwig	580	20	10	19
3. OK1-20677	252	12	09	12
4. Y2-7111/A	144	09	07	09

AWARDS:

Usual awards to top stations in each class.

ENTRIES:

Use one log per band. Logs must be received by June 20th to qualify, so it is advisable to use air mail. Logs should contain band, date/time in GMT, callsign, exchanges sent and received, points, and multipliers. Enclose a summary score sheet along with any comments. Address entries to: G. Vulpetti I2VTT, PO Box 37, I-22063 Cantu, Italy.

ROCKY MOUNTAIN DIVISION QSO PARTY

Starts: 1800 GMT May 9
Ends: 2400 GMT May 10

The contest is sponsored by the Arapahoe Radio Club of Littleton CO. Stations outside the Rocky Mountain Division may work any station. The same station may be worked once per band, although mobile stations may be worked each time they change counties. Novices will indicate as "/N", club stations with "/C", and mobiles with "/M". RM states are: Colorado, Wyoming, Utah, and New Mexico.

EXCHANGE:

RS(T) and state; Rocky Mountain Division stations will also send their county.

FREQUENCIES:

3560, 7060, 14060, 21060, 28060, 3900, 14300, 21370, 28570, 3725, 7125, 21125, 28125.

SCORING:

Phone QSOs count 1 point; CW QSOs count 2 points; QSOs with club stations count 3 points. RM entries multiply QSO points by number of states, RM counties, and DX countries (not to exceed 5 DX multipliers). Others multiply QSO points by the number of RM states and counties worked per band. All stations add following bonus points after multiplying by the appropriate multiplier. Working 5 RM Division Novices—add 50 points. RM mobiles operating from 3 or more counties—add 100 points. RM club stations with at least 5 operators (minimum 10 QSOs per operator)—add 100 points.

ENTRIES AND AWARDS:

Awards will be issued to the high scorer in each state and DX country, high Novice in each state, and to high-score mobile in each RM Division state. Club stations in the Division will compete by state for the Silver Dollar Award.

Submit logs, with large SASE, by June 15th to: Buster Boatman KA0CLS, 8973 W. Harvard Drive, Lakewood CO 80227.

DARC CORONA 10-METER RTTY CONTEST

Contest Period: 1100 to 1700 GMT May 10

This is the second of four tests during the year sponsored by the DARC eV to promote RTTY activity on the 10-meter band. Each of the four tests is scored separately. Use the recommended portions of the 10-meter band.

EXCHANGE:

RST, QSO number, and name.

SCORING:

Each station can be contacted only once. Each completed two-way RTTY QSO is worth 1 point. Multipliers include the WAE and DXCC lists and each district in W/K, VE/VO, and VK. The final score is the total number of QSOs times the total multiplier.

AWARDS:

Plaques will be awarded to the leading stations in each class with a reasonable score present. Operating classes include: Class A for single- or multi-op and Class B for SWLs.

ENTRIES:

Logs must contain name, call, and full address of participant. Also show class, times in GMT, exchange, and final score. SWLs apply the rules accordingly. Logs must be received within 30 days after each test. Send all entries to: Klaus K. Zielski DF7FB, PO Box 1147, D-6455 Erlensee, West Germany.

The remaining contest periods are on September 26th and November 8th.

DOGWOOD FESTIVAL QSO PARTY

1300 to 2200 GMT May 16

The annual Dogwood Festival celebrated in Fairfield CT will also be observed on the air by members of the Greater Fairfield Amateur Radio Association with a Dogwood Festival QSO Party. Members of the club will operate on six bands with the club call WB1CQO. A special commemorative QSL card will be available to confirm each QSO upon receipt of an SASE or IRCs to QSL manager Grace von Stein KA1JT, 248 Euclid Avenue, Fairfield CT 06432.

Dogwood Festival stations will operate on SSB using 3975, 7235, 14330, 21420, and 28710. FM operation will be on 146.55 simplex.

The Dogwood Festival marks the blossoming of 30,000 pink and white dogwood trees in the town of 55,000 persons. The Festival began in 1936, although the original trees were imported from Japan in 1895 and earlier.

FLORIDA QSO PARTY

Contest Periods:
1400 to 1900 GMT May 16
0001 to 0500 GMT May 17
1500 to 2300 GMT May 17

This is the 16th annual Florida QSO Party sponsored by *Florida Skip*. All amateurs worldwide are eligible and invited to participate. All amateur bands may be used. All stations will separate phone and CW logs; phone and CW are separate contests. A station may be worked once on each band mode. Neither crossband nor crossmode contacts will count for contest credit.

RESULTS

3rd VK-ZL-OCEANIA RTTY CONTEST

Single Operator

1. DJ8JC	793,282	(101)

AWARDS

I3FIJE—Silver plaque and certificate
I5MYL—Plaque and certificate
W4CQI—Plaque and certificate
Horst Bellenberger—Plaque and certificate

Florida stations may work other Florida stations, but for contest points only. Out-of-state stations may not work each other for contest credit. Contacts made on repeaters do not count for credit.

Florida stations will be divided into two classes. Class A stations are those operating portable or mobile on emergency power and running 200 Watts or less (CW or PEP phone) inside Florida but outside of their home counties. Class B stations are all other stations operating in Florida.

Each entrant agrees to be bound by the provisions of the contest announcement, the regulations of the applicable licensing authority, and decisions of the *Florida Skip* Contest Committee, which are final.

EXCHANGE:

Florida stations send RS(T) and county of operation. Others send RS(T) and US state, Canadian province, or country.

FREQUENCIES:

Phone—3945, 7279, 14319, 21379, 28579, 50.2, 146.52.
CW—3555, 7055, 14055, 21055, 28055.

SCORING:

Florida stations count one point per QSO with out-of-state or other Florida stations. Multiplier is the sum of states (49 maximum), provinces (12 maximum), and DX countries (27 maximum) actually worked; maximum multiplier is 88. Others count 2 points per QSO with each Florida station. Multiplier is the number of different Florida counties worked (67 maximum). Final score is the product of QSO points and the multiplier. Class A stations *only* multiply score by 1.5 to obtain final total.

AWARDS:

Certificates for phone and CW to the top single-operator score in each state, province, DX country, and each Florida county. There are also 5 plaques to be awarded as follows: high single operator in Florida and out-of-state, CW and phone, and to the Florida club with the highest aggregate score.

ENTRIES:

Phone and CW entries *are to be separated*! Along with legible logs in chronological order, a summary sheet is required with each entry. The summary sheet must contain score, number of QSOs, multiplier, station's callsign, entry class, and number of Florida counties, power source for Class-A entries; county, state, province, country, or region of operation, callsigns of all operators/loggers if multi-op; name of club if part of a club aggregate score; name and address TYPED or PRINTED in BLOCK LETTERS; and a signed declaration that all rules and regulations have been observed. All stations making more than 200 QSOs should also include a dupe sheet. Include a 15-cent stamp for contest results from a future issue of *Florida Skip*. At the discretion of the contest committee, stations and/or operators may be disqualified for improper reporting, excessive dupes, errors in multiplier lists, unreadable logs, obvious cheating, etc. Anyone disqualified in this year's Florida QSO Party will be barred from the contest next year. All entries must be received on or before June 15th; late DX entries will be accepted within reason. Mail all entries to: *Florida Skip* Contest Committee, PO Box 501, Miami Springs FL 33166.

MASSACHUSETTS QSO PARTY

Starts: 1600 GMT May 16
Ends: 0200 GMT May 18

Sponsored by the Greater New Bedford Contesters. A station may be worked once per band. Phone and CW are considered separate bands. No crossband or repeater contacts are permitted. Mobiles and portables may be contacted each time a county change takes place.

EXCHANGE:

RS(T) and state, VE province, or Massachusetts county.

SCORING:

All stations count 2 points for each completed SSB exchange and 4 points for each completed CW exchange. Massachusetts stations then take the total QSO points and multiply by the total number of Massachusetts counties, states, and provinces worked to compute the final score. Others multiply the total QSO points by the total number of Massachusetts counties worked. Add a 50-point bonus to the total score for each sponsor worked; each can be worked only once for bonus points. The sponsors are W1FJI, N1AS, and K1KJT. DX stations count for QSO points only.

FREQUENCIES:

Phone—1820, 3960, 7260, 14290, 21390, 28590, and 50.110.
CW—1810, 3560, 7060, 7120, 14060, 21060, 21120, 28060, and 28120.

Use of FM simplex is encouraged. Please use CW in CW bands only!

AWARDS:

Certificates will be awarded to 1st, 2nd, and 3rd place winners in each Massachusetts county as well as each state. Two special awards will be given out: one to the amateur radio club with the highest aggregate score in Massachusetts with a minimum of three logs, and a 2nd award to the station in Massachusetts who submits the all-time highest number of QSOs. The current record is held by K1GSK with 1483 QSOs in the 1979 Massachusetts QSO Party. In addition, a certificate will be given to stations working all 3 sponsors.

ENTRIES:

Logs must show date, time, band, mode, callsign, state and province worked, and exchange RS(T). Submit a separate summary sheet along with the logs. Summary sheet should include name, call, mailing address, club affiliation for aggregate score, total QSO points, multipliers claimed, and total score. Deadline for mailing is June 30th. For awards and results include $0.30 postage (no envelope). Address entries to: Larry Purcell N1AS, 146 Armour Street, New Bedford MA 02740.

MICHIGAN QSO PARTY

Contest Periods:
1800 GMT Saturday, May 16 to 0300 GMT Sunday, May 17
1100 GMT Sunday, May 17 to 0200 GMT Monday, May 18

This year's QSO party will be sponsored by the Oak Park ARC. Phone and CW are combined into one contest. Michigan stations can work Michigan counties for multipliers. A station may be contacted once on each band/mode. Portable/mobiles may be counted as new contacts each time they change counties.

EXCHANGE:

RS(T), QSO number, QTH as state, country, or Michigan county.

FREQUENCIES:

Phone—1815, 3905, 7280, 14280, 21380, 28580.
CW—1810, 3540, 3725, 7035, 7125, 14035, 21035, 21125, 28035, 28125.
VHF—50.125, 145.025.

SCORING:

Multipliers are counted only once. Michigan stations score 1 point per phone QSO and multiply by the total number of states, countries, and Michigan counties. Each CW contact counts 2 points; KL7 and KH6 count as states; VE counts as a country. Maximum multiplier is 85.

Others take QSO points times the total number of Michigan counties. QSO points are 1 point per phone QSO and 2 points per CW QSO. Maximum multiplier is 83.

All stations score 5 points for each club station contact with W8MB.

VHF only entries: same as above except multipliers per VHF band are added together for total multiplier. Score 5 points for each OSCAR QSO. No repeater contacts are allowed.

AWARDS:

Only single-operator stations qualify. Michigan trophies to high Michigan score, high Michigan (Upper Peninsula) score, high aggregate club score. Plaque to high VHF only entry and high mobile. Certificates to high score in each county with a minimum of 30 QSOs. Out-of-state high trophy and certificates for high score in each state and country.

ENTRIES:

A summary sheet is requested showing the scoring and other pertinent information, name and address in BLOCK LETTERS, and a signed declaration that all rules and regulations have been observed. Michigan stations include club name for combined club score. Party contacts do not count toward the Michigan Achievement Award unless one fact about Michigan is communicated. Members of the Michigan Week QSO Party Committee are not eligible for individual awards. Decisions of the Contest Com-

mittee are final. Results will be final on July 31st and will be mailed to all entries. Mailing deadline is June 30th to: Mark Shaw K8ED, 3810 Woodman, Troy MI 48084.

MICHIGAN ACHIEVEMENT AWARD

This will be the 23rd year that hams have had their own program to publicize Michigan and its products. Just as for the past years, the Governor will award Achievement Certificates to hams who take part in telling the world of Michigan's unlimited resources, opportunities, and advantages. Certificates are awarded on the following basis:

1. A Michigan ham submits log information and names and addresses (if possible) of 15 or more contacts made to out-of-state or DX hams with information regarding Michigan.

2. An out-of-state ham, including Canada, submits log information and names and addresses (if possible) of at least 5 Michigan hams who relate facts to him about Michigan.

3. A foreign ham, excluding any resident of Canada, submits the call letters and name/address plus log information for at least one Michigan ham who has told him about Michigan.

Only QSOs made during Michigan Week, May 16-23, will be considered valid. All applications for certificates must be postmarked by July 1st and mailed to: Governor William Milliken, Lansing MI 48902.

EUROPE AND AFRICA GIANT RTTY FLASH

Contest Periods:
1400 to 2400 GMT May 23
0800 to 1800 GMT May 24

This is the 13th annual contest by the IATG Radiocommunications as part of a new promotional program for RTTY. The basic purpose of this contest is to increase interest in RTTY, but even more to increase interest in intercontinental contacts. The contest committee is open to and welcomes suggestions which might improve future contests.

Use all bands from 80 to 10 meters. Remember that all contacts must be on RTTY! Each station may be contacted once per band.

EXCHANGE:

RST, QSO number, and your continent.

SCORING:

QSO points are as follows: QSO on 80 or 40 meters = 2 points; QSO on 20 meters = 3 points; QSO on 15 meters = 6 points; QSO on 10 meters = 8 points.

No points or multipliers for contacts with one's own country. Only 2-way RTTY contacts are valid.

Multipliers are given for countries and continents. Use the DXCC Country List plus count each call area of VE/VO, W/K, VK, PY, LU, JA, and UAØ/9 as separate countries. A multiplier is given for each country worked on the 20 through 10 meter bands. No multipliers for contacts on 80 or 40 meters with one's own continent. A separate multiplier may be claimed for the same country if a different band is used (maximum of 3 times). Only countries which appear in at least 3 other logs will be valid multipliers. One's own country is not valid as a multiplier. For contacts with Europe and Africa, both the sender and the receiver will receive 100 points as a multiplier. Each of the remaining continents receives 50 points. An additional 100 points will be given for each contact with Europe and Africa on 15 or 10 meters.

The final score is the total QSO points times the total number of countries times the total number of continents plus the total points for EU and AF stations worked. Example: 600 QSO points times 10 countries worked times 100 continent points equals 600,000 plus 20 stations of EU and AF worked on 15-10 meters giving a grand total of 602,000 points.

ATTENTION! Two promotional periods are included in the contest: 1700 to 1800 GMT May 23 and 1000 to 1100 GMT May 24. Stations operating from North America, South America, Australia, Oceania, and Asia contacting EU and AF during these hours will double their points for these periods.

Beginner handicaps are offered to RTTYers entering logs in the contest who have not participated in previous contests. They will receive an additional 5% of their final score. Additional handicaps are offered as 10% of the total final score for the winner of previous RTTY Championships or 8% of the total final score for the winner of one or more preceding RTTY contests.

SWLs may also enter and they should use the same scoring rules. A separate results table will be made for these entries.

AWARDS:

Prizes, as usual, are reserved for the four first place winners. Consolation prizes will also be awarded.

ENTRIES:

Use separate log sheets for each band. Logs must contain date/time in GMT, callsign, RST and QSO number sent/received, country and continent multipliers, points, and final score. The contest disqualification criteria used by the ARRL in its contest apply also to this contest. Failure to observe any rules will result in exclusion of the entry for the final results and any such log will be considered as a check log. Logs compiling errors exceeding 10% of the final score will also be excluded from the final standing. Each log received becomes the property of the IATG Radiocommunications and will not be returned. The decision of the organizing committee in any dispute will be final and any subsequent controversy may not be referred to the Civil Court. Remember, the contest is valid towards the final standing of the 5 Continent World Championship.

In order to qualify, all logs must be received no later than June 30th and sent to: Prof. Franco Fanti, Via A. Dallolio n 19, Bologna 40139, Italy.

FUN!

John Edwards KI2U
78-56 86th Street
Glendale NY 11385

When I mentioned to a friend that I was going to do a column on the American Radio Relay League, his reaction was, "Don't do it; they're too easy a target!"

True, but it's also too great a temptation. Few topics supply as much grist for the old puzzle mill as our friends in Newington. When it comes to creating offbeat, unusual, and downright strange tidbits of ham radio trivia, the ARRL provides your "FUN!" columnist with a veritable field day (if you should pardon the term) of material. (For instance, how many nongovernmental organizations do you know that once had their own "Department of Defense?")

All in all, the ARRL should make for a very entertaining column. Even more interesting, one might say, than evaluating the League's financial status from their annual report.

ELEMENT 1—CROSSWORD PUZZLE
(Illustration 1)

Across

1 League's original QTH
5 What incentive licensing made many hams
7 Propagation form (abbr.)
8 ARRL message service (abbr.)

33 Personal radio service (abbr.)

ELEMENT 2—MATCHING "Who Am I?"

Below are self-descriptions of various people associated with the ARRL. Match these statements with the names listed.

1) In 1914, I co-founded the ARRL with Hiram Percy Maxim. _____
2) Although I drew the cartoons and illustrations that became an integral part of all League publications, my death was all but ignored by *QST*. _____
3) Back in 1953, when W1AW caught fire and suffered severe damage, I was the last operator on duty. The fire burned a hole through the floor directly behind the main operating console. _____
4) After being a sales representative for Motorola, I joined the ARRL as *QST*'s managing editor in 1956. Today, I am the day-to-day boss of the League, having even more direct power than President Dannals. _____
5) I write those "folksy" humor articles for *QST* that you have to read twice to "figger out" what I'm saying. _____
6) In 1971, I led the ARRL delegation to the ITU Space Conference—a conference that took away 99.99684% of our satellite frequencies. _____
7) I wrote *QST*'s "How's DX?" column for over 30 years. Since my retirement, *QST*'s had a problem finding anyone to write the column for more than 30 hours. _____
8) I was the League's first general counsel and the author of its "Amateur's Code." _____
9) For many years, I was *QST*'s VHF columnist. In 1946, I took part in the first 6- to 10-meter crossband transatlantic QSO. _____
10) In the June 1964 *QST*, I wrote an article extolling the virtues of incentive licensing. However, by the beginning of the 1980s, I still hadn't achieved my Extra-class ticket. _____

A) Robert W. Denniston W0DX B) John Troster W6ISQ C) William Orr W6SAI D) Rod Newkirk W9BRD E) Richard Baldwin W1RU F) Michael Samanka KA2AEV G) Edward Tilton W1HDQ H) Paul Segal I) Murray Powell W1QIS J) Phil Gildersleeve W1CJD K) Clarence Tuska 1WD

ELEMENT 3—MULTIPLE CHOICE

1) W1AW pays its operators. Since hams are not allowed to accept material compensation for their radio efforts, how is this legal?
   1) It isn't
   2) By the grace of FCC Part 97.112, which allows compensation to operators of club stations under certain restricted circumstances
   3) W1AW operators may be paid only when the station isn't actually transmitting
   4) W1AW operators aren't paid
2) According to the ARRL's "Amateur's Code," to whom does a ham "owe his amateur radio to"?
   1) The FCC
   2) Radio pioneers
   3) The credit company
   4) The ARRL
3) Back in 1977, when Jack Anderson ripped amateur radio apart in his column, how long did it take the League to form its reply?
   1) 24 hours
   2) 1 week
   3) President Dannals met with Anderson to discuss the column 2 weeks after it appeared
   4) The ARRL never formally responded
4) Under ordinary circumstances, how much does *QST* pay writers of top-notch construction articles?
   1) Nothing
   2) $50
   3) $200
   4) A 2-year ARRL membership
5) What did the ARRL "slay" in 1977?
   1) 220-MHz CB
   2) Amateur radio
   3) The "Russian Woodpecker"
   4) Mobile logging requirements

ELEMENT 4—TRUE-FALSE

		True	False
1)	W1AW is a club station.	____	____
2)	The 1980 ARRL Hudson Division Convention was actually held in the Atlantic Division.	____	____
3)	The ARRL's goodwill is worth only one dollar.	____	____
4)	In 1979, out of the 2,238 people who applied for ARRL code proficiency certificates and stickers, only 90 failed.	____	____
5)	Under a special agreement with the FCC, W1AW is allowed to run up to five kilowatts of dc input power.	____	____
6)	The ARRL is in favor of giving phone privileges to Novices.	____	____
7)	When the FCC raised Novice power restrictions from 75 to 250 Watts in 1976, the League expressed its disapproval.	____	____

8) The League's headquarters in Newington CT stands on the site of a former mental hospital. ____ ____
9) Eugene C. Woodruff was the founder of "Amateurs for Action," an anti-ARRL organization of the 1950s. ____ ____
10) "The American Radio Relay League" was almost named, at its inception, "The American Amateur Radio League." ____ ____

ELEMENT 5—MISSED QUOTES

Below are misquotes of familiar League slogans, titles, and expressions. Your task is to restore them to their correct form.

1) "You'll find RIT in a League publication."
2) "Of, by, and against the amateur."
3) "Devoted entirely to itself."
4) "Calling some radio amateurs; this is W1AW."
5) "The World Above 50 kHz"
6) "Ham's Wild World"
7) "Silent Key Night"
8) "Kinky Hints for the Radio Amateur"
9) "YL Views and News"
10) "Frequency Estimating Test"

THE ANSWERS

Element 1:
See illustration 1A.

Element 2:
1-K, 2-J, 3-I, 4-E, 5-B, 6-A, 7-D, 8-H, 9-G, 10-C

Element 3:
1-2 The so-called "W1AW clause."
2-4 Who else?
3-4 Instead, they asked members to write their local newspapers.
4-1 You get what you pay for.
5-1 To paraphrase Mark Twain: The reports of 220-MHz CB's death are greatly exaggerated.

Element 4:
1 True It's actually licensed to the "ARRL Headquarters Operators Club."
2 True For convenience of division members, no doubt.
3 True That's what it says in their Annual Report—I think it's an overestimate.
4 True Gee, and who says code is hard to learn?
5 False W1AW must live with the same rules as the rest of us. Serves them right.
6 True They've even filed a petition with the FCC to allow Novices phone on 220 MHz. See Element 3, question 5.
7 True W2HD got so mad, he even wrote a letter.
8 False No comment.
9 False Not likely, since Woodruff was League president from 1936-1940.
10 True It would have made a better name, but could you imagine griping about the AARL?

Element 5:
1 "You'll find it in a League publication."
2 "Of, by, and for the amateur."
3 "Devoted entirely to amateur radio."
4 "Calling all radio amateurs; this is W1AW."
5 "The World Above 50 MHz (mc.)"
6 "Ham's Wide World"
7 "Straight Key Night"
8 "Hints and Kinks for the Radio Amateur"
9 "YL News and Views"
10 "Frequency Measuring Test"

SCORING

Element 1:
Twenty points for the completed puzzle, or ½ point for each question correctly answered.

H	A	R	T	F	O	R	D		M	A	D
A		E		L		A		T	E		I
N	T	S		A		N	B	V	M		V
D		P	E	G		G	O		B	C	I
B	E	E			M	E	M	B	E	R	S
O		C	T			R	B		R		I
O	P	T		K	H			Z	L		O
K	M			L	O	N	G		I	O	N
		B	T		O		I		F		S
O	O	S			V	A	L	V	E		
T			D		E			O		C	W
C	O	U	N	T	R	Y	C	L	U	B	

Illustration 1A.

Element 2:
Two points for each correct answer.

Element 3:
Four points for each correct answer.

Element 4:
Two points for each correct answer.

Element 5:
Two points for each quote corrected.

Think you know your League? Let's see.

1-20	points—Received a congratulatory form letter from W2HD after passing Novice test
21-40	points—Once threw away a League promotional mailing
41-60	points—Ardent member
61-80	points—You wear your 25-year pin to work
81-100+	points—Charter Life Member

By the way, about the ARRL "Department of Defense" mentioned at the start of this column: That was the League's World War I plan to organize an amateur civil defense network in the event of an enemy invasion. It's a good thing the Kaiser never tried invading Connecticut; his forces would have been no match against dozens of amateurs carrying hand-held spark rigs.

HAM HELP

The Sinclair/Microace Amateur Users' Group has located a source for those impossible-to-find connectors for the ZX-80 computer. Amateurs wishing to trade amateur-related programs and information such as this source may contact me at the address below.

Marty Irons K2MI
46 Magic Circle Drive
Goshen NY 10924
(914)-294-9462 after 9:00 pm

I have just completed a Signetics 2650 microcomputer (2650 motherboard with S-100 expansion to 64K) and would like to send RTTY and CW with this unit. I can't, however, find anything on a demodulator from my rig to the micro. Can anybody help? Thank you.

7046 Hollywood Blvd.
Hollywood CA 90028

Last month, I presented the Lew Collins W1GXT letter in which he expressed his reaction to the proposed six-meter band plan. This month you can read my reply.

I finally have the time to properly answer your letter. Many apologies for the delay, but as my earlier quick note explained, the "bug had me down for a bit." Enough on that. On to six meters and your letter. I will try at this time to respond on a point-by-point basis, addressing the points on which we seem to disagree.

First, I am far from a "casual" six-meter user. Rather, I have been on that band almost constantly since 1959 when I was first licensed in New York as WA2HVK. I believe this was detailed in depth in the column. By "user," I think you mean one who engages in day-to-day two-way operation. To me, the term "user" means anyone who spends any time concerned with the band. Going with my definition, and, again referring to what I have printed on the subject in regard to my own six-meter operation, I can say with assurance that my interest is far from casual.

I see that the one major point we do agree on is that six meters is by and large a "dead band," mainly due to the TVI problem. Two meters was a good out, and most amateurs took it. I am, however, well aware of the die-hards and their DX record this past year. In fact, I make it a point to try to call Ray Clark K5ZMS at SMIRK at least once a month for news updates. The 50-to-72-MHz "across the pond" activity was something else again. I can remember back in the early 1960s when many of us were trying for such QSOs, most of the time with no success. If only "C.C. & R's" didn't exist out here! Three elements in one's attic leaves a lot to be desired, especially when your attic is surrounded by rather high hills.

I think our greatest disagreement seems to lie in the area of technical parameters. In your analysis, you view only the operation of today's "minority" who inhabit the band on FM, using some excellent equipment. Something akin to the two-meter band about 15 years ago. The era of the 80D, RCA LD-150, and alike. In that day, the FMer on two meters was a "minority." He was the technically competent amateur who had the ability to take a piece of high-quality land-mobile FM equipment and convert it to amateur use. But it was not until the amateur manufacturers came along with off-the-shelf, ready-to-use equipment that FM activity really began to grow on two meters. Radios like the Drake TR-22 and Regency HR-2 are what "made" two meters. Not the converted Motracs and Mastrs. For the average amateur, the latter were just too limited in scope of operation to gain widespread acceptance.

Keep in mind that not every amateur is a technological wizard. A goodly number of today's hams have no interest whatsoever in building or converting. Maybe it's a sad commentary, but it's true, nonetheless. Hams today want off-the-shelf, ready-to-use radios. They want the type of features that no converted land-mobile radio can ever give. They are willing to sacrifice the extreme quality found in land-mobile equipment in favor of something small enough to carry in a briefcase, yet giving them total access to an entire band. Look at the equipment marketed for two meters. What sells best? The answer is self evident.

If six meters is to grow, it must be made easy for the average amateur to gain access to the band. This means mass-appeal amateur radio equipment, available off-the-shelf. Again, it's in the same situation as two meters was back a few years ago. I remember well the way that those of us using our Big-M radios felt toward the newcomer with his rice-box special. Even today, there are amateurs in my area who will not talk with another station on two-meter FM unless he knows for sure that he is in QSO with another amateur using a converted land-mobile radio.

But for a band to grow, it takes people. For people to come onto an amateur band takes being able to walk into a local radio store, plunk down his hard-earned bucks, and buy the rig of his dreams. And, for the rig of his dreams to be made available in the first place means that we amateurs must give definite assurance to those who build the equipment we use that we will purchase their wares. The only conceivable way for this to happen in relation to the six-meter band, especially in regard to FM, is for this nation to adopt one specific bandplan—and then stick to it.

It matters not who writes the bandplan. It does matter that it be one that lends itself to the ease of manufacture of equipment directly oriented toward the general amateur populace. This, so that a lawyer, doctor, or anyone, technically oriented or not, can turn it on and get on the air. Yes, it means going against one of the traditions of amateur radio. The tradition of believing that when one's amateur license arrives in the mail, he or she is automatically elevated to the exalted position of electronic wizard, par excellence. Reality says that those days are gone and probably will never return. How often does one find a U.S. DXer operating with home-built equipment these days? Very, very seldom.

I take a simple view. The bands belong to the majority, not any specific finite minority. I foresee any mass inhabitation of six meters taking place when and only when the equipment manufacturers begin to offer the type of equipment that the average amateur wants. Equipment that operates "out of the box." This is today's world of amateur radio, for better or worse.

For six meters, or any band, to be safe from outside attack means population and use. Not just casual use by a select few, which I think you and I qualify under, but, rather, it means use by the masses, the availability of the band, on a day-to-day basis akin to today's use of two meters. It means further deregulation and internal voluntary standards from the amateur community. It means that we start today and select a bandplan. A plan that is best for Joe Ham and Joe Ham Equipment Manufacturer. It will also mean the same sort of confrontation developing between those with commercial land-mobile radios and others who will be the newcomers. The latter is but human nature. If you have something all to yourself and you know how good it is, you might not be inclined to want to share it with others. This was the way it was in regard to the early days of FM on two meters and the way it is in regard to FM on six these days.

It is not for me to argue the merits of any specific bandplan. My only call is that we stop the procrastination and move forward now, lest we wait and find that "10-4, Good Buddy" has made his move, and it's too late for us to make ours. When I published the bandplan, I invited readers to pick it apart and put it back together. Thus far, yours has been the only in-depth letter received, and I am sincerely grateful that you took the time and trouble to do so. Maybe it will encourage others to do likewise.

As to the modelers' channels, I had expected a flurry of mail on that and was surprised that little was received at first. A few weeks later, I learned the possible reason. As you are aware by now, the Academy of Model Aeronautics had requested a hearing before the Commission in the hope of gaining permission for non-amateurs to use six meters for model control, under the supervision of an amateur. I suspect that many modelers felt that this would go through as requested, so they didn't bother to write.

I began to receive very negative commentary from the modelers the week of November 12, 1980. As you are probably well aware, on November 6, 1980, the Commission not only turned the request down, but went so far as to question the rationale of permitting anyone, amateurs included, the use of six meters for radio remote control of models. While I have yet to get a copy of the proposed plain-language amateur regulations (P.R. Docket 80-279), I have heard rumors that the latter is the case. I have ordered a copy and

W2NSD/1 NEVER SAY DIE

editorial by Wayne Green

from page 8

isn't all that difficult if you go about it the right way. I think I could set up a system which would bring in tens of thousands of technicians for the military...and it wouldn't cost all that much either.

Also, the military seems to have had some problems with winning wars in recent years. The Vietnam conflict comes to mind in this respect. If I could have gotten my ideas on the subject where they would have done some good, we might have saved 99% of the money we threw into that silly war... saved tens of thousands of lives...and beat the hell out of communism. Before you decide without a trial that I'm a nut, I might explain that I have written about my scheme in *73* and gotten compliments on it. The plan, which I'll cover again if anyone is interested, is an oriental approach to outsmarting the enemy instead of trying to outfight him. New concept.

Much of my life is spent in solving problems, so I tend to think in those terms. Often I find it helpful to take ideas from many different fields and put them together to form a new concept. My grandfather made his fortune as an inventor and I think a lot the way he did. Fantastic man. Multipledisciplinarianism, they call it.

One of the reasons that I read as widely as I do is so that I will have ideas from many fields. I whip through some 200 magazines a month, covering not only the ham, electronics, computer, CB, radio, autosound, hi-fi, radar, satellite, microwave, and other associated fields, but also things like skin diving, photography, UFOs, psychology, politics, news, skiing, cars, premiums, business, stock market, travel, and so on.

The idea for outsmarting the North Vietnamese came from a mixture of ideas which I found in New Caledonia, Yugoslavia, and Singapore. Once I had the idea, I explored it with friends when I was visiting other countries such as Burma, India, Thailand, and so on. They all thought it would have to work.

That's one of the beauties of amateur radio...anywhere you go in the world you have friends ...people you can sit down with to talk about ideas like that.

Lately, in the interests of saving time, I've been giving some of my talks at shows via video tape. I did offer to send a tape to the War College with my ideas. We'll see how that goes over.

HOW WOULD YOU LIKE TO *BE* DX?

Early on in my ham publishing career, I managed to get a taste of working from the DX end of things. I'd gotten particularly bitten by the DX bug back in 1946, immediately after the war. My first move after getting out of the Navy was to spend one summer on vacation in my home town in New Hampshire, complete with a kilowatt ham station and an enormous vee beam. What a summer *that* was!

Then, on returning to college in the fall, I moved my ham station there and set it up in the basement of the fraternity house. There was room in the yard for a pair of Twin-Three beams, so I began to set the world on fire, knocking off new countries as fast as they surfaced. I will never forget some of those exciting contacts.

One morning I was up early and heard a very weak station calling CQ. He was in the DX band, so I called him blind. It was a W7-something, portable something. I only called once because I felt so foolish calling a station when I hadn't heard the callsign. He came right back, with his signal gradually improving. It was W7IMW/C7 in Tientsin, China. He was running ten Watts and a very long wire ...and I was the *only* station he was hearing. I got the QSL card for the contact, too!

After I became the editor of *CQ*, I managed to get on a DXpedition to Navassa Island in 1958. That was an exciting trip for me, though it was a sort of last minute change from our original plan to go to Clipperton. I'd managed to get a license for Clipperton, but transportation fell through. I then got a license for Navassa...KC4AF...so we went there. Years later, when I was in Tahiti for a few days, I checked and found that my FO8AS ticket was still good, so I operated from Tahiti with it in 1966.

Down through the years, I've been on several DXpeditions... even going again to Navassa in 1972. I've also visited almost one hundred countries now and operated from over half of them ...usually using the gear of a local ham. I've been on the hot end of the pileups hundreds of times...and it *is* a thrill.

Some of the more interesting places I've operated from were Afghanistan as YA1NSD, Teheran from the American Embassy, Beirut, Damascus, Nairobi, Katmandu, Delhi, Amman, Suva, New Caledonia, Western Samoa, American Samoa, Wake Island, Korea, including the DMZ at Panmunjom, Australia, New Zealand, and many, many more. Each is a story...and I have the slides to show for most of them. I'm working toward being able to put some of these stories on video cassette, so that they may be available for club showings soon. I'll let you know.

Even with the responsibility of running four monthly magazines plus Instant Software, I still manage to get away occasionally for a visit to some relatively rare spot. During the last year I managed to visit Japan, Korea, Taiwan, Hong Kong, Macao, China, Guatemala, Hawaii, Germany, France, Belgium, Netherlands, Luxembourg, Berlin (East and West), England, Ireland, and Northern Ireland. I met with hams in most of those countries and gave talks in Wiesbaden, Paris, Hawaii, Taiwan, and Tokyo.

You may be sure that *73* will always reflect my personal interest in both working DX and DXpeditioning...as well as my other ham interests such as RTTY, SSTV, OSCAR, microwaves, VHF, repeaters...etc.

WORK WAYNE WRAGGED

After operating for a few days in the Turks and Caicos Islands in March...partly during the DX contest...I found that this was a great way to sort of keep in touch with the readers of *73*. I can do this to some degree from Peterborough, but it really takes a location in the Caribbean to reach all of the US...and, besides, it is more fun that way.

My present plans call for me to be able to get away for a few days in May...so I'm hoping to get down to St. Lucia (J6L) and get on the air for a couple of days...probably May 16-17th. Look for me around 21.380 during the day, 28.70 if 10m is open, 14.210 and 14.285 in the evenings, and 3.820 during the late evenings. I'll try to be around those frequencies so you can find me.

While I obviously am not able to talk business over the air, I will welcome any questions... on just about any subject. I'll also cook up a special QSL for the expedition. I'm going to try to arrange further such trips, so we might eventually come up with a certificate if you can work me in N-places.

That brings up an idea. I wonder how many of you have QSL cards from me from more than ten locations? We might come up with some sort of recognition for those who have managed to contact me in a number of different spots. In the past I've been on the air from something near 50 countries.

Keep in mind that I am also an avid scuba diver, so I'll be out in the mornings checking out the reefs with an underwater camera. I had a couple fine dives at Providenciales Island in the Turks and Caicos. I'll write about that more when the pictures come back.

WIN A FREE BOOK!

We are reviving the "Circuits^2" feature in *73*. Just send in your favorite circuit, along with a *brief* description of its operation or intended use. (Make sure that it works!) If we print it, you'll get your choice of a book from our Radio Bookshop. Be sure to include your book choice with your circuit.

AWARDS

Bill Gosney WB7BFK
Micro-80, Inc.
2665 North Busby Road
Oak Harbor WA 98277

COLONIAL AMERICAN AWARD

To qualify for a very beautiful red, white, and blue award, applicants must work all the original thirteen colony states. In case you need help to identify which states they are: Connecticut, Delaware, Georgia, Maryland, Massachusetts, New Hampshire, New Jersey, New York, North Carolina, Pennsylvania, Rhode Island, South Carolina, and Virginia.

Have your list of contacts verified by at least two amateurs or a local radio club secretary. Enclose your application and $1.00 award fee to: Certificate World Awards, Rte. 2, Box 72, Fulton MS 38843.

THE OLD SOUTH AWARD

Depicting a scroll listing the eleven states of the Old South, this award is made available to amateurs of the world who make one contact with each of the states of Alabama, Arkansas, Florida, Georgia, Louisiana, Mississippi, North Carolina, South Carolina, Tennessee, Texas, and Virginia.

Have your list of contacts verified by two amateurs and enclose this list with an award fee of $1.00 or six IRCs to: Certificate World Awards, Rte. 2, Box 72, Fulton MS 38843.

VIRGINVILLE

1981 marks the 50th anniversary of the founding of the Reading Radio Club. This year, many events will be held commemorating their Golden Jubilee.

The first event is a Special Events operation with the club traveling to Berks County's foremost spot, Virginville. Station W3BN will operate on 3.950, 7.250, 14.300, 21.400, 29.500, and 146.31/.91 MHz phone and 7.125 and 14.045 MHz (alternating between phone) CW from 1300 to 2200 UTC on May 3. Special commemorative QSL cards are available—QSL club direct. For info, write Reading Radio Club, Inc., PO Box 124, Reading PA 19603.

WINDMILL ISLAND

Amateur radio station K8DAA will be operating from Windmill Island in Holland, Michigan, on Saturday, May 16, during the annual Tulip Time Festival. Certificates will be sent to amateurs contacting K8DAA between 1400 and 2300 UTC. Approximate frequencies will *be* 7.125, 7.275, 21.125, and 21.425 MHz. Please send QSL and 75¢ to Jack Van Voorst WD8RNQ, 8737 Summit Court, Zeeland MI 49464.

FIDDLERS' PICNIC

The Alamance Amateur Radio Club, K4EG, will operate a special events station at the Alamance County Historical Museum during the Fiddlers' Picnic fund-raising event for the museum. The Historical Museum building is the birthplace of Edwin M. Holt, a pioneer in textile manufacturing in the South.

Operation will be on May 16-17, 1981, from 1600 to 2300 UTC. Frequencies of operation will be 7.260 and 21.360 MHz, General phone. An attractive certificate will be issued on receipt of QSL and legal-size SASE. For information and QSL submission, contact Alamance ARC, c/o Gary Hills KA4KJI, 2416-C Huntington Rd., Burlington NC 27215.

DISAPPEARING SUN

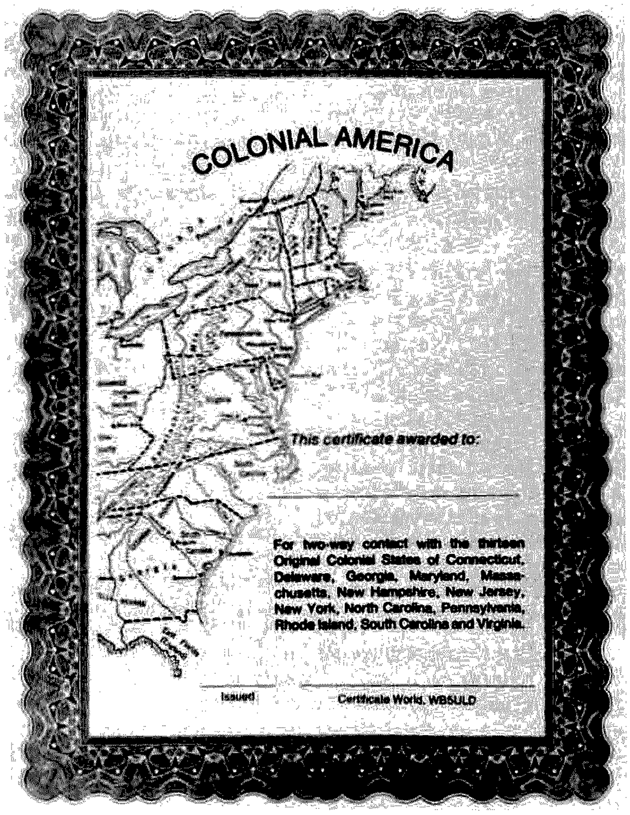
W7AQ, the Yakima Amateur Radio Club, will run a commemoration of The Day the Sun Disappeared, which occurred on May 18, 1980, when Mount St. Helens erupted. Yakima, Washington, which is 80 miles N.E. of the volcano, saw the sun disappear by 10:30 am and did not see the light of day until 7:00 am the next morning. May 18th was "black as midnight" by 12:00 noon.

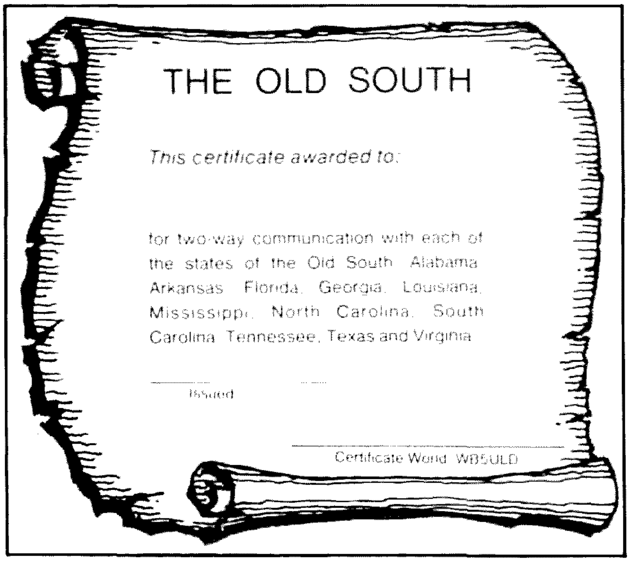
W7AQ was celebrating its 50th year of existence with its hamfest that morning. At 8:38 am, word was received that the mountain had a major eruption. Near 9:30, they watched a "thunderstorm front approach out of a clear blue sky." Then the rain of dust started. Over 600,000 tons of volcanic dust fell within the city of Yakima alone. Everything was covered with up to one inch of dust and ash. Local and visiting amateurs provided emergency communications and handled information traffic for the next three days.

Commemorate with them from 1700 to 0200 UTC on May 17-18. Listen for W7AQ on 28.660, 21.370, 14.280, 7.285, and 3.940 on SSB, and 28.120, 21.130, 14.040, 7.140, and 3.740 for CW. A special-event QSL card will be available: Send an SASE to W7AQ, Yakima Amateur Radio Club, PO Box 9211, Yakima WA 98909. For further information, contact Kenneth Sahn KA7DWH, PO Box 9211, Yakima WA 98909.

MACKINAC ISLAND

The Blossomland Amateur Radio Association will sponsor a bicentennial expedition to Mackinac Island (Mackinac





County) during the Michigan QSO Party, May 16-17. Operation on 80-10 CW and SSB, with 2-meter SSB is planned; look for W8MAI. Enclose an SASE for special certificate and mail to PO Box 175, St. Joseph MI 49085. For additional information, contact Dale H. Cole KA9FKU, 52480 Winding Waters, Elkhart IN 46514.

STORK TOWER AWARD

A new award from the Canadians in West Germany is called the Stork Tower Award. Sponsored by the Lahr Amateur Radio Club, all contacts must be made on or after July 1, 1980.

Contact 5 club members and the club station, DA2CF, using all bands or modes. Mail a list with full name, call, and US$1 or 5 IRCs to LARC, PO Box 2771, CFPO 5000, via Belleville, Ontario, Canada KOK 3R0. Remember —only members of the Lahr Amateur Radio Club count for this award.

MOSCOW OLYMPICS?

The Mid-South VHF Association will operate a special-event station on May 22-25, 1981, at the "Moscow Olympics" in Moscow, Tennessee. This event is a spoof of the Moscow, USSR, Games and will include cow-chip throwing, skillet tossing, and tobacco chewing contests, among others. Proceeds from the "Moscow Olympics" will go to the establishment of an educational fund for the children of those men killed in the attempted hostage rescue in Iran. A special QSL commemorating the event is planned. Look for the "Olympics" on 40, 20, and 15. The station call will be KU4K (closest Russian-looking call). QSL to Ervin Abies KU4K, PO Box 88, Moscow TN 38057. For further info, contact Jo Ann Wilder at (901)-523-5310.

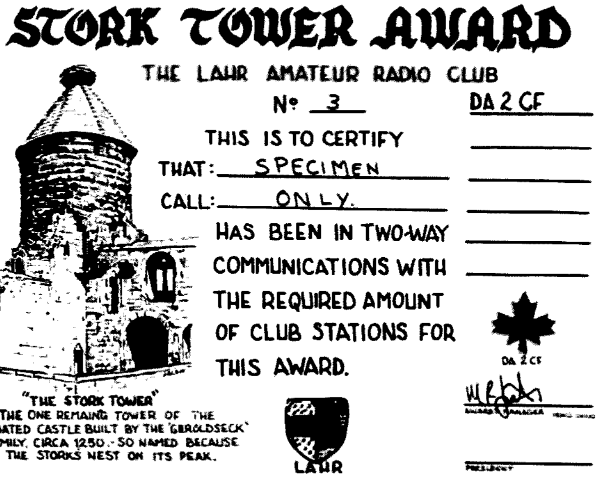
OE SERIES AUSTRIAN AWARD

WAOE. To qualify for the Worked All Austria Award, stations in OE, DL, OK, HA, YU, I, HB, and HB0 must contact all nine call areas of OE-land with three stations in each call area using at least two bands, one of which must be on either the 40- or 80-meter band. Call areas OE4 and OE9 count as one call area. Stations in other European countries require the same amount of contacts on at least two bands without the 40- and 80-meter restriction. Stations outside Europe need one contact with any eight of the nine call areas.

Awards are available for all CW, all phone, 2 × SSB, 1.8 MHz, VHF, and mixed modes. To be valid, all contacts must be made on or after April 1, 1954.

To apply, prepare a list of contacts and have it verified by a local radio club secretary. Enclose your application with an award fee of 10 IRCs to: OE1FMC, Awards Manager, Postfach 999, A-1014 Vienna, Austria.

WAOE/160. This one separates the men from the boys. Stations in Austria require two contacts in eight of the nine call areas. Stations in Europe out-



side Austria require one contact with eight of the nine call areas. Stations outside Europe need only to contact one station in four of the nine call areas. Remember, each of these contacts must be two-way communications on the 160-meter band. A real toughie for us west coast boys!

To apply, have your list of contacts verified by a local radio club secretary. Enclose this list with 10 IRCs and forward to: OE1FMC, Awards Manager, Postfach 999, A-1014 Vienna, Austria.

SAN BENITO COUNTY

The Gabilan ARC will put San Benito County, California, on the air on Sunday, May 31. Times of operation will be from 0800 to 1600 PDT, and will be extended if activity is good. Operating frequencies will be 28.775 and 21.400 USB, and 28.175 and 21.175 slow-speed CW.

A special certificate and QSL card will be sent to those who confirm with an SASE. QSL to John Daudet KB6IT, 2001 Scenic Circle, Hollister CA 95023.

LIECHTENSTEIN DXPEDITION

The Wiesbaden Amateur Radio Club will sponsor its sixth annual DXpedition to Liechtenstein during May 23-31, 1981. The callsign will be DA1WA/HB0. The QSL Manager is DJ0LC. His address, which is good in the DX *Callbook*, is Dr. Hugo Jakobljevich, Am Weinberg 10, 6200 Wiesbaden-Auringen, West Germany. Stateside QSLs, along with an enclosed SASE, may be sent to Mr. Stephen Hutchins, Box 4573, APO New York 09109.

Continued

NINE DRAGONS AWARD CORRECTION

Phil Weaver of the Hong Kong Amateur Radio Transmitting Society writes to tell us that the fee for the Nine Dragons Award is US$3 or 25 IRCs *not* the US$2 as listed in the February Awards column. Sorry for the inconvenience, Phil.

This year's operating modes will be: CW, phone (SSB), and RTTY on all bands; OSCAR Mode A; CW and SSB on 160 meters; and 6-meter/10-meter crossband operations. For American Novices, CW operations will be attempted at 3.725 and 21.120 MHz, ±5 kHz, between 1900 and 2100 hours EST.

The object of this year's DXpedition, besides having fun, is to provide amateurs around the world the opportunity to work "HBØ". For further information, contact Hugo about CW operations, Steve about 160-meter operations, or Claude R. Matchette DA1PN/WB3CEA, HHC V Corps (G-2), APO New York 09079.

A DEEP SUBJECT

The month of May provides us with the opportunity to work three submarines in *three* different locations. The *USS Croaker, USS Ling,* and *USS Cod* will be activated for at least one weekend each. Can you fathom this? Read on.

USS CROAKER

The Amateur Radio and Electronics Association of New Jersey (AREA-NJ) radio club will conduct a mini-DXpedition to Groton, Connecticut, on May 2 and 3. The club will operate from the radio room of the submarine *USS Croaker* which will be moored in the Thames River. This event will commemorate the anniversary of the sub's commission into service during WWII. A special QSL card will be issued to all amateurs establishing contact with the submarine. The following is a schedule of the activities:

Time (UTC)	Band	Frequency
1400-1600	15m phone	21.355-21.375
1600-1800	15m CW	21.035-21.045
1800-2000	15m CW	21.110-21.120
2000-2200	15m phone	21.355-21.375
2200-2400	20m CW	14.035-14.045
0000-0200	80m phone	3.900-3.920
0200-0400	80m CW	3.73-3.75
0400-0600	40m CW	7.035-7.045
0600-0800	40m phone	7.235-7.255
0800-1000	20m phone	14.300-14.320

1200-1400	15m phone	21.355-21.375
1400-1600	15m CW	21.035-21.045

During the entire operation, 2-meter FM will be conducted on both local as well as simplex frequencies. For information, contact Charles Burke WA2SLK, Box 164A, RD #1, Georgia Tavern Road, Farmingdale NJ 07727.

USS LING

On May 16, Armed Forces Day, the Meadowlands Amateur Radio Association will be on board the *USS Ling* (SS 297) docked on the Hackensack River in Hackensack, New Jersey, and will be operating under club station call N2BMN. Possible frequencies are: 14,260-285, 21,360-365, and 7,230-235 kHz, and 146.520 and 146.550 MHz from 1500 to 2000 UTC. For further information, contact Ralph Francavilla N2BMN (MARA), 154 Redneck Ave, Little Ferry NJ 07643.

USS COD

Once more, the members of the Parma Radio Club will be operating from the WWII submarine *USS Cod,* using the club call, K8UZW. The *USS Cod* is on permanent display in Cleveland, Ohio. Operations will start on May 30 and run through September 6 every weekend with the exception of Field Day weekend.

An attractive certificate will be awarded for 2-way contacts from the ship upon receipt of a QSL card and 30¢ for postage. All bands will be operated, 10 to 80; band conditions will dictate band of major activity. Send QSLs to WD8RZG. For info, contact Don Winner WD8RZG, 8927 Torrance Ave, Brooklyn OH 44144.

SCHOLARSHIP INFO

The Atlanta Radio Club announces the third annual competition for two $500 cash scholarships. Each scholarship will go to a licensed amateur entering college in the fall of 1981. Deadline for completed applications is May 31, 1981; request an application from ARC Scholarship, 259 Weatherstone Parkway, Marietta GA 30067.

NEBRASKALAND DAYS

A week-long statewide celebration, Nebraskaland Days, an event held the third week of June every year in North Platte, Nebraska, the home of Buffalo Bill Cody, features the Buffalo Bill Rodeo. This rodeo is named after North Platte's famous resident, who started rodeo as we know it today in North Platte.

In honor of Buffalo Bill and to celebrate Nebraskaland Days, the North Platte Amateur Radio Club will operate a special station, WØCXH, from 1800 to 0000Z on June 13-14. Frequencies used will be 21.400, 14.290, and 7.250 MHz SSB, and 21.150 CW plus or minus QRM.

A handsome certificate will be available for contact with the station. Send a legal-size SASE to North Platte Amateur Radio Club, PO Box 994, North Platte NE 69101.

OLD MAN RIVER AWARD

A very unique award can be yours by meeting the requirements of the Old Man River achievement award. The certificate pictures the mighty Mississippi River and the ten states bordering this river. To qualify, applicants must make two-way contact with all ten states: Arkansas, Illinois, Iowa, Kentucky, Louisiana, Minnesota, Mississippi, Missouri, Tennessee, and Wisconsin.

Prepare a list of contacts and have it verified by at least two amateurs. Enclose an award fee of $1.00 or six IRCs to: Certificate World Awards, Rte. 2, Box 72, Fulton MS 38843.

PODUNK CENTER

On the weekend of May 9, Podunk Center, Iowa (yes, there is such a place!), will be back on the air. Air time not known yet, but all bands, SSB and CW, are contemplated. 146.52 FM simplex will also be monitored. Calls are WØYBV, CW; WØANZ, SSB.

A Novice band might be used. CW operation will occur 25 kHz up from bottom, split frequency. Most SSB operation should be in the General class portion of the band.

QSL requests must be accompanied by an SASE or proper postage (or IRC equivalent). A special QSL will be sent in answer to such requests. Cards should be sent to the *Callbook* address of either station.

For more information, write Charles J. Ellis WØYBV, 2304 Storm Street, Ames IA 50010.

WORKED ALL BERMUDA AWARD

Sponsored by the Radio Society of Bermuda, this award is made available to licensed amateurs throughout the world.

To qualify, applicants must work one station in each of the nine parishes of Bermuda. Only one mobile or portable station may be claimed for credit. The rest must be fixed stations. The city of Hamilton is in Pembroke Parish and not in Hamilton Parish as you would be led to believe.

WORKED ALL CHILE AWARD

Sponsored by the Radio Club of Chile, applicants who wish to meet the requirements of this award will have to confirm contact with eight of the ten call districts in Chile.

To be valid, all contacts must be made after November, 1945. While there are no band or mode restrictions, special endorsements will recognize band or mode accomplishments if request is made at the time of application.

To apply, prepare a list of contacts and submit this list with your QSL cards to the awards manager. Enclose with your application and cards an award fee of 6 IRCs to cover return postage of your cards. Forward to: Radio Club of Chile, Casilla 13630, Santiago, Chile, South America.

CE 25-P AWARD

Also sponsored by the Radio Club of Chile, this award requires South American applicants to make contact with 25 of the 31 divisions of Chile. Ap-

plicants outside South America need only to contact 20 out of the maximum 31 divisions.

Do not send QSL cards! Have your list of contacts verified by at least two fellow amateurs. Enclose your list with 3 IRCs to: Radio Club of Chile, Casilla 13630, Santiago, Chile, South America.

The Divisions for the CE 25-P Award are: CE1—Tarapaca, Antofagasta, Atacama; CE2—Coquimbo, Aconoagua, Valparaiso; CE3—Santiago; CE4—Taloa, O'Higgins, Colchagua, Curico, Linares, Maule, Nuble; CE5—Concepcion, Arauco, Bio Bio, Malleco; CE6—Cautin, Valvidia, Osborno; CE7—Llanquihue,Chiloe, Aysen; CE8—Magel Lanes, Tierra Del Fuego; CE9—AA-AM Antarctica, AN-AZ South Shetland Islands; CE0Z—Juan Fernandez Archipelago; CE0A—Easter Island; and CE0X—San Felix and San Ambrosio Islands.

ISLAND DX AWARD

On the DX scene, the Whidbey Island DX Club is proud to announce the continuation of the world renowned Island DX Award.

Sponsored by the Whidbey Island DX club, the Island DX Award is available to all licensed amateurs and SWL stations throughout the world.

This award is offered for CW, SSB, SSTV, RTTY, OSCAR, and single and multiband accomplishments. A total of 50 islands is required for the basic award. Endorsements are given in increments of 50 islands, up to and including the maximum number of islands possible.

The *73 Magazine* Work the World DX Listing is used as the basis for determining what is or what is not a DX country. Only DX countries which are bonafide islands will count. See the list of countries.

To be valid, all contacts must be made after October 1, 1977. There is no mode or band restriction but endorsements will be recognized if requested at the time of application.

To apply, prepare a list of contacts in prefix order. Applications received in any other order will be returned to sender. Include on your list, the station callsign, IDX island name, band, mode, date, and GMT. Do not send QSL cards! Have your list verified by at least two amateurs or a radio club secretary. You must have QSL cards in your possession at the time application is made.

Forward your verified list, an award fee of $3.00, and a business-size SASE to: Whidbey Island DX Club, 2665 North Busby Road, Oak Harbor WA 98277.

NORTH DAKOTA/ SOUTH DAKOTA

Two activities are made available courtesy of the Central Iowa DX Association.

On the weekend of 30 May, two special-event stations will be on the air from one or the other or both of these states. Which one (or both) will not be known until the day of operation. 80-10-meter operation is

Island DX Listing. The IDX Award program depicts DXCC countries which are bona-fide "islands" as recognized by the National Geographic Society. First criterion, however: They must be a DXCC country as stated on the ARRL DX Countries List. Any qualifying DXCC countries either omitted from this list by error or those which have been recognized for DXCC after the release of this listing will be added to the IDX List when it is printed next.

contemplated. SSB and CW modes will be used and 144.52 simplex FM will be monitored. Calls will be WØYBV, CW, and WØANZ, SSB.

Novice band operation is possible. Most CW operation will occur 25 kHz from the low end of the band and split frequencies will be used. Most SSB operation will occur in the General class band.

QSLs will not be sent to stations flagrantly violating ethics of good operating or failing to respond positively to suggestions made by these special event stations. Stations calling on the transmitting frequency will not be answered. QSL requests must be accompanied by an SASE or proper postage (or IRC equivalent). Cards should be sent to the *Callbook* address or either station.

County Hunters—Attention! En route to the site, these two stations will operate mobile. The route will pass through several Iowa counties from Des Moines to I-29. From there, I-29 will be followed to the North Dakota/South Dakota line.

WORKED ZAMBIA AWARD

Available to licensed amateurs of the world, the Worked All Zambia Award is sponsored by the Radio Society of Zambia.

To qualify for the award, applicants in zones 36, 37, and 38 require 20 points while all other stations need to accumulate a total of 10 points. Each 9J2 station counts 1 point on 7, 14, 21, and 28 MHz. On 1.8 and 3.5 MHz, 9J2 contacts will count 2 points. The same station may be worked on different bands for award credit. Other prefixes used by Zambian stations will count double points.

To apply, do not send QSL cards! Have your list of confirmed contacts verified by at least two fellow amateurs or a local radio club secretary. It should be mentioned that separate award classes are available for all CW, all phone, all AM, and mixed modes.

Enclose your verified list of contacts with an award fee of $2.00 or 7 IRCs to Awards Manager, RSZ, Daniel Soko, Box 1831, Ndola, Zambia.

EL GULFO DE MEXICO AWARD

This award, in the form of an old map showing the Gulf and Spanish exploration, is available to those amateurs making contact with the states of Alabama, Florida, Louisiana, Mississippi, and Texas. There are no band or mode restrictions nor any time limit.

To apply for the El Gulfo de Mexico Award, have your list of contacts verified by two amateurs or a local radio club secretary. Enclose your application along with an award fee of $1.00 or six IRCs to: Certificate World Awards, Rte. 2, Box 72, Fulton MS 38843.

WORKED ALL YUGOSLAVIA AWARD

To be valid, all contacts must be made on and after February 1, 1950. To qualify, YU applicants must confirm contact with 10 stations in each of the six YU republics. European stations require confirmation for contact with three stations in each of the six republics, while all other stations require two station contacts within each of the six Yugoslav republics. In all three categories, applicants must utilize at least two amateur bands. YU7, YUØ, 4N, 4O, and YT count for the republic from which the QSO was made.

To apply for this award, prepare a list of contacts and have it authenticated by a radio club secretary. Enclose this verified list and award fee of 5 IRCs to Awards Manager, SRJ, Box 48, 11001 Belgrade, Yugoslavia.

ESPANA DIPLOMA

From Spain comes word of the Worked All Spain Award. To be valid, all contacts must be made on or after January 1, 1952.

To qualify, award applicants must work 125 different EA stations in eight call districts and have a minimim of three contacts from each of the eight districts. The same station may be worked only once regardless of band or mode. The Spanish provinces and call areas include: EA1, EA2, EA3, EA4, EA5, EA6, EA7, and EA8.

To apply, have your list of contacts verified by a local radio club official. Do not send QSL cards! Forward your verified list and the award fee of 10 IRCS to URE, PO Box 220, Madrid, Spain. We are told that SWL stations may also apply under the same award requirements on a heard basis.

MOUNT ST. HELENS AWARD

The Clark County Amateur Radio Club, W7AIA, announces the Mount St. Helens Award to commemorate the 1980 eruption of this active volcano in the Cascade range of North America. A unique full-color photographic award of the awesome eruption on May 18, 1980, is available to all radio amateurs throughout the world. Two opportunities, with no mode or band restrictions, are provided to qualify for the award.

1) Contact eight or more stations in the Mount St. Helens area of southwest Washington State (Clark, Cowlitz, Skamania, or Lewis counties) after March 27, 1980, the date of the mountain's first eruption in the past 123 years.

2) Make one contact with W7AIA (Clark County Amateur Radio Club) during its operation from 0200 UTC May 16 until 0200 May 18, 1981, to mark the first anniversary of the disastrous eruption which took the life of Reid Blackburn KA7AMF who was a member of this club.

Send log information (no QSLs, please) including call of station worked, date, signal report, and $2.00 or 9 IRCs to Award Manager, CCARC, PO Box 1424, Vancouver WA 98668.

Proceeds from this fund will go to the Reid Blackburn Memorial Scholarship Fund which has been established by *The Columbian*, a Vancouver newspaper. A brief resume of the mountain's volcanic activity and a short report of Mr. Blackburn's involvement will be included with the award.

LION CITY AWARD

Available to amateurs worldwide, this DX award requires that contacts be made on and after September 10, 1969, to be valid. Stations in zone 28 require a minimum of 40 station contacts in Singapore. All other stations in the world require only 20 individual contacts with Singapore.

Once confirmation is received, have your contacts verified by at least two amateurs and forward this list with 10 IRCs to the award manager: MARTS, PO Box 725, Penang, Malaysia.

WORKED ALL MALAYSIA AWARD

Also sponsored by the Malaysian Amateur Radio Transmitting Society (MARTS), the requirements of the Worked All Malaysia Award are quite challenging. Applicants must work 10 9M2 stations, 10 9V1 stations, 1 VS5 station, 1 9M6 station and 1 9M8 station. There are on band or mode requirements but endorsements are available.

To apply, forward a verified list of contacts and an award fee of 5 IRCs to: MARTS, PO Box 725, Penang, Malaysia.

SAMUEL F. B. MORSE ANNIVERSARY

The Chelsa Communications Club of Chelsea, Michigan, is sponsoring a special event from May 18 to May 24, 1981, to celebrate the anniversary of Samuel F. B. Morse's first coded telegraph message. The message was sent in 1844 between Baltimore, Maryland, and Washington, DC, a distance of 41 miles.

Frequencies of operation are: phone 3.900, 7.235, 14.285, 21.360, and 28.510, and CW 15 kHz up from top of all Novice frequencies.

A special certificate will be sent to all those who send a QSL card with contact number and a #10 SASE envelope to Chelsea ARC Manager N8AYY, 5191 Esch Road, Manchester MI 48158.

ALL BAND TRAP ANTENNAS!

LEAKY LINES

Dave Mann K2AGZ
3 Daniel Lane
Kinnelon NJ 07405

The traditional concept of avoiding controversial subject matter while on the air is becoming markedly weakened; people seem to feel that because standards have become measurably looser in other areas of public communications (television, films, books, theater, etc.), there is no need to preserve those taboos which, after all, are no longer consistent with our present level of sophistication and are relics of a bygone puritanical age.

As strong as the ham liberationists have become, however, there is still a sizable number of amateurs who feel that we must not drop certain standards of morality. Those who have allowed a loosening to occur in their own operations are frequently importuned by anonymous fellow amateurs (who rarely identify themselves by callsigns) to steer clear of touchy subject matter. The proscribed topics, usually, are politics, religion, and sex, not necessarily in that order.

Of course, when dealing with large numbers of individuals of varying backgrounds, one finds an enormous range of opinion stretching from one extreme to the other. What you consider acceptable may only raise my hackles, and what I may find perfectly innocent may give you apoplexy! If this is carried far enough, you come to the inevitable conclusion that there is no such thing as a topic that is not anathema to someone or other. Thus, if you were to accede to all the demands of the self-styled censors, you would scarcely be able to discuss anything at all!

We live in an era with fewer restrictions on speech and behavior than ever before. At no former time can I recall such phenomena as "streakers" and people "mooning" in the windows of automobiles. And the language that spews forth into the living rooms from TV sets is unprecedented. It is not difficult for the impressionable to infer that nowadays anything goes, bar nothing.

But just because there is a plenitude of foul four-letter Anglo-Saxonisms in books, movies, magazines, and television, it doesn't mean that they have now taken their place alongside of mother, apple pie, and Old Glory!

A writing colleague recently sent me some cassettes, transcribed off the air. I believe they were recorded on the frequency of one specific repeater in a large city on the west coast. I have listened to them carefully and have come to the conclusion that even though I am a strong proponent of free speech, I have to take a firm stand against the sort of unbridled filth on those cassettes. Just because Oliver Wendell Holmes' famous quotation on this subject is restricted to the hollering of "Fire!" in a crowded theater, some bubble-heads have concluded that it's perfectly legitimate to say anything else. They have also concluded that civil rights gains of recent decades have validated the theory that an individual has the right to do practically anything, and that this right must be defended against the "tyranny of the majority." They hold that individual freedoms are more precious than collective rights.

This view is quite a distortion, to say the least.

But let's not talk about obscene language alone. After all, foul language is nothing new; it has been on the scene almost as long as language itself. I can recall that when I was in the Army there was a certain universally applied adjective. It was so common that nobody paid any attention to it.

"Pass the ——butter, willya buddy?"

"Sure. Watcha doin' this ——weekend?"

"Gonna go home and see my ——family. How about you?"

"Nah! I'm gonna stay on the ——base."

As I say, it became so ubiquitous that it lost its offensiveness. And perhaps that is what has happened while we weren't looking. Someone once said that eternal vigilance is the price of liberty. Well, obviously, it is also the price of the maintenance of high behavioral standards. If they are not watched and guarded, they can deteriorate right under our very noses.

There is another element, *however, that* may be a good deal worse than foul language, something that has been building for a long time. Like dry rot in foundation timbers, it has spread virtually unnoticed, and it could threaten not only the microcosm of ham radio, but the entire society itself.

Someone has passed along a letter written by a licensed amateur, a diatribe which he sends as his QSL. It is one of the most scurrilous pieces of racist propaganda and filth that I have ever seen, and believe me, I have seen plenty! Like most of its type, this one masks its venomous poison behind a facade of phony patriotism and religiosity. It uses well-documented deliberate slanders to construct a tissue of mendacious and malicious lies, and propagandizes in exactly the same way that similar pieces of fascist material were spread during the height of the fifth column activity immediately preceding our entry into World War II. The line is the same old Hitlerite garbage that once plunged humanity into a global conflict that snuffed out millions of lives before it was quelled!

The letter itself is awful enough. But the disclosure that this same vile filth is being regularly transmitted on our amateur frequencies is an abomination! Apparently there are nets being operated by this seditionist and his confederates. According to the letter there are also two publications which are pushed by these people as well, tracts designed for the purpose of spreading the false gospel of racism and religious intolerance. And in the classic manner of most such groups, this one relies upon the traditional fear and distrust of communism to whip up the passions.

Steps have been initiated to bring the matter to the attention of authorities so that it can be determined whether radio regulations are being violated. But I fully expect that when and if a hearing takes place, these extremist lunatics will bombard the FCC with all sorts of arguments claiming that their civil rights are being violated. They will accuse their adversaries of persecution and will righteously and piously scream that they are victims of a communist plot. And they will call upon "real Americans" to join them in a common crusade against the forces of Satanic bolshevism.

The question poses a paradox. We who believe in freedom of speech generally oppose all limits and boundaries. Yet, there is such a thing as a "clear and present danger." Much to our disadvantage we learned that no matter how small and seemingly weak such groups may seem, they can gain unbelievable strength and power. Hitler began with a small group of tavern rowdies. Castro's insurgence started with just a few revolutionaries, perhaps fifteen or twenty. Khomeini's circle consisted of a few fanatics quartered in a cheap *room in* Paris, thousands of miles away from Teheran!

Let no one dismiss such carryings-on as inconsequential trifles simply because they seem ineffectual and their advocates are few in number. At the same time, we can rely, I feel, on the common sense of the overwhelming majority of our ham colleagues, and can be confident that such appeals to prejudice will fall on deaf ears. There is little to suggest that any but the most ignorant and those already infected with the virus of racism would be foolish enough to be swayed by such arrant nonsense.

It does present us with a dilemma, however, and that is simply this. Should the amateur frequencies be available as a base of operations and a sanctuary for those whose ultimate aim is the destruction of traditional democratic concepts? Do we want our ham bands used as an avenue for alien propaganda programs, and if we do not, how can they be stopped without we ourselves violating the principles of free speech which we hold dear?

RTTY LOOP

Marc I. Leavey, M.D. WA3AJR
4006 Winlee Road
Randallstown MD 21133

A couple of years back, I acquired something called an "EPUT meter." Taking up about a foot of vertical space in a nineteen-inch rack, it had over a score of tubes and sported its own cooling fan. Its face was adorned with many knobs and switches, central to which were six columns, each composed of ten neon bulbs which shone through a mask to display the numerals zero through nine. EPUT? That stood for Events Per Unit Time. Yes, this power-hungry monster was my first frequency counter, able to count up to 100 kHz, and originally costing several thousand dollars.

Despite its limitations, the EPUT meter proved invaluable when setting up my RTTY station. AFSK tones, filters, an ST-6, and countless other projects were aligned with its help. But it was big and power-hungry, and its 100-kHz frequency limit put quite a crimp in its applications.

Then, at a hamfest, I saw a little box for sale, the likes of which I just could not believe. A frequency counter the size of one of the EPUT meter's readout modules, that could literally run rings around the old unit.

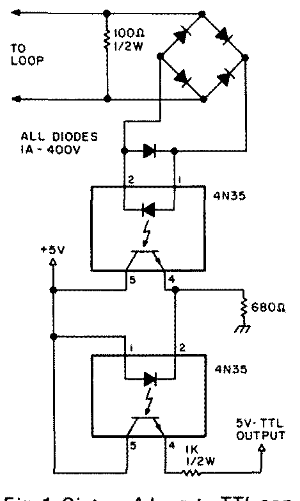

Fig. 1. Sixty-mA loop-to-TTL conversion. . . with inversion.

The Ramsey Electronics Model CT-70 frequency counter, advertised right here in the pages of *73*, was what caught my eye. Let's take a look at what it does. The basic counter's range is from 10 Hz to 5.5 MHz. Within that range, sensitivity is under 50 mV and resolution with a one-second gate is to one Hertz. The stated accuracy of the straight counter is to within one part per million at normal operating temperatures. That is the equivalent of .0025 Hz at a 2500-Hz tone frequency, or 3.6 Hz when tuning up on 3620-kHz RTTY. Close enough for my standards.

A shift in the input circuit extends the range ten times to 55 MHz with the loss of only one digit of resolution. Sensitivity and accuracy stay the same, only now the readout is within 10 Hz. Since the stated accuracy at, say, 50 MHz would be within 50 Hz, the units digit would not be significant and it would make little sense to show one.

As if all that were not enough, at the flick of a switch a divide-by-ten prescaler is placed in the line. This extends the range through 550 MHz, with a stated sensitivity under 150 mV. Now the resolution is to within 100 Hz, again consistent with the accuracy of the device.

If you need faster updates than once per second and are willing to take a ten-percent penalty for doing it, a one-tenth-second gate is available. Some math will show that with a one-tenth-second gate what you gain in time you lose in accuracy, so no useful information is lost when the display is truncated to a bottom limit of 10 Hz, 100 Hz, and 1000 Hz on each of the three ranges, respectively.

Input to the counter is through a front-panel BNC jack; very convenient and easy to get to. Power is supplied by four internal AA-size cells. I chose to purchase the counter equipped with nickel-cadmium rechargeable cells and a wall-plug charger. Makes a very convenient package.

Also, a couple of accessories are available to make life easier. A short antenna mounted on a swivel-BNC plug allows easy rf monitoring. I didn't get one and, after the third antenna I jury-rigged fell apart, I wished I had. Several probes also are offered, all of which look like good deals.

How much, you wonder? The counter itself comes in just under $100, assembled and tested. If you are on a tight budget, you can order it as a kit and save fifteen bucks. The nicads and charger will run another thirteen dollars, and the antenna another eight. All in all, a very good value for the money. (Ramsey offers several other counters, by the way, both higher and lower in price. Check their ad in the back of the book for current details. If you write them, be sure to mention RTTY Loop, OK?)

So, why am I so hepped up on a counter, here in a RTTY column? Do you have an idea how many ways a counter can be used in a RTTY station? We can start with the obvious, measuring the tones put out by the AFSK generator to be sure it is accurate. Are you using direct rf FSK? Put the counter on the speaker leads of your receiver and zero beat your mark signal. Now send a space, and will you look at that! The counter shows your shift, directly!

Are you involved in nets? I have been, and there is nothing so aggravating to a net control of a RTTY station than to see stations spread up and down a few hundred Hertz. Boy, it really does! Hurt, that is. Now when I am on a MARS net where the mean frequency is 4035 kHz and the control station says to put your mark on 4035.085 kHz, straddling the center frequency with 170-Hz shift, that is exactly where I am.

Digitally inclined? An easy way to set up the baud rate of the RTTY program you have been working on is to run a bit chain to the counter. Remember that bit rate is related to baud rate, and that means frequency. Sixty words per minute is 45.45 baud; see if yours comes close.

Need more ideas? Just look at the number of counter-related articles in the pages of *73* over the past few years and you may get more of a feel for it.

Our circuit this month comes from Vince Vielhaber KA8CSH and Joe Stragea KA8GOS. They needed a TTL-level signal to key an AFSK generator off a 60-mA loop. Only one problem—the logic high, +5 volts, needed to be present during space rather than mark. The need to isolate the AFSK unit from the line, as well as the unusual biasing requirement, resulted in the circuit in Fig. 1. Two optoisolators are cascaded, with the second one operating as an inverter to the first. If you need the signal out in the conventional, mark-high fashion, the second optoisolator could be eliminated and the signal derived only from the first. Looks like a nice piece of work, fellows, and thanks.

Regards also to Alfred Giuiiano K3QJO, who passes along his interest in the 6800-related RTTY articles. More are certainly on the way, both here and in the rest of the magazine. Remember, *73* is the leader in articles of technical interest to the active amateur, and the place to start for RTTY is right here, in RTTY Loop.

LETTERS

RADIO SHACK CLASSES

I had to write to congratulate you on your great idea for ham classes through Radio Shack. I have often wondered why more stores don't use this as a valuable advertising tool as well as a way to gain numerous new customers. I have taught Novice classes at a local community college with good results, but I think your idea is by far a better approach.

I would like to offer any support or services I could to help this idea advance. I will approach the local owner of the 5-6 Radio Shack stores in the Spokane area with the idea or will let you approach the company as a whole.

I am looking forward to hearing how this idea develops. If the company isn't interested for its 6000+ stores, how about its computer centers in many large cities? These already have training facilities for use so would be ideal with no new expense to the company.

For ease in starting, the Radio Shack book *From 5 Watts to 1000 Watts*, their code oscillator on a board, plus a cheap speaker and code key could be put together in a small package. I think a $25 fee would be plenty unless you anticipate paying the instructor. If so, I would say not more than $100 for a 10-week class.

Again, it's a great idea, and let me know if I can be of any help in making it a success.

Dan Robinson WB7PSO
Spokane WA

ARRL SWINDLE

To All Indiana Amateur Radio Clubs and Interested Hams:

As you probably are aware by now, the present leadership of the ARRL has swindled Central Division League members out of their right to be represented on the ARRL Board by the candidate of their choice. In good faith, Central Division League members recently cast secret ballots for their choice to serve as Central Division Director for the next two years. However, two days before the votes were to be counted, one of the candidates, Director Don C. Miller W9NTP, was summoned to appear before the ARRL Executive Committee the following day to answer charges of alleged election misconduct. Upon his arrival at League headquarters on this incredibly short notice, Don was ushered into a private meeting with President Harry Dannals. After being browbeaten and verbally abused by Dannals, and other League officials for over two hours, Don, at Dannals' direction, signed a letter of resignation as Director for the term ending December 31, 1980. Two other points about this meeting should be noted. First, prior to his signing the resignation, but unbeknownst to Don, the League's Executive Committee (out of Don's presence) had reviewed all of the various allegations of misconduct that had been made and voted to dismiss them and to proceed with the previously scheduled November 20 ballot count. The second and most significant is that Don Miller never withdrew as a candidate in the pending election nor was given a hearing on the question of his alleged disqualification.

Upon his return from Connecticut, Don reported the above cited events to the Officers and Directors of the IRCC. The undersigned then directed our attorneys to conduct a complete investigation of the situation. A report of that investigation and advice on potential future action was delivered to a special meeting of the IRCC Directors held on December 16, 1980, in Indianapolis. The two conclusions reached at that meeting were, one, that Don was clearly not guilty of any wrongdoing that would disqualify him from office, and two, that if Don was willing to participate in any necessary legal action, the IRCC would raise the necessary funds and sue to vindicate our members' rights to have their votes counted and results certified. Several phone calls and letters to the ARRL and their attorneys made it absolutely clear that they would not accede to our demand unless ordered to do so by a court. If ordered by a court to seat Don Miller as Director, they would then initiate proceedings to oust him as a Director on frivolous charges. When Don was notified of this situation, he advised the IRCC that he appreciated our efforts but did not wish to become a party to the lawsuit. Our attorneys have advised us that without Don, we have no real chance to win a case. So, reluctantly for this term, our hands are tied—legally at least.

Although the League has apparently won the battle, the war is not over; in fact, it has just begun. By their patent disregard for the rights of our members in the Central Division, the current League leadership demonstrated to us the acute necessity to take immediate action to protect our rights from this type of outrage in the future. Our first task is obvious: We must do everything we can to strengthen the one statewide organization that can and will speak for the interests of hams in our state and in the entire Division. We must not be cheated again—our strength lies in numbers. If you are presently a member of a Radio Club or know of *any* Indiana radio club or organization who is not yet a member of the IRCC, please seek their support in becoming a constituent member of the Council. The annual dues for clubs is $7.50. Individual members may subscribe to the *Bison*, the Council publication, for $5.00 annually. Our membership chairman is George Ransford W9VMT, 6015 Forest View Drive, Indianapolis IN 46208, phone (317)-255-6180. Remember, your right to have anything is solely dependent on your resolve to do something about it. Help us help all Indiana hams.

GETTING A JOB

Last week I sent your personnel department a resume describing my virtues, but this week I have second thoughts and wonder if I would be a good staff member considering my experience of the last two weeks.

I thought I would write and give you a few facts which have been evident to me during the last few days regarding the hiring of middle-aged technicians in their fifties. Do they retire? Do they start new careers? Or do they just fade away like WWII surplus until there just ain't no more?

I'm pretty typical. I worked in radio stations and two-way shops most of my life, and finally started my own shop in 1962. After 18 years of grappling with the pressure of customers, government, and raising children, I sold my shop to a young man who is now doing real well with it. I realized enough from the deal to retire—for one year.

The relief from the pressure is great, but the not working is awful. Some began to say, "If he would eat, let him also work." This is a true saying, so I hit the streets, made phone calls, and filled the mail boxes with resumes. My goal was to connect with an industrial outfit who needed a competent electronics man.

Now, when I say competent, I don't mean brilliant, but rather consistent, loyal, and industrious. The kind of fellow I would hire would also be imaginative and empathetic to his fellow workers, not necessarily brilliant. The brilliant technicians are called "hot shots" around here, and, though having more smarts than Bill Buckley, they cannot be trusted to come in from a hail of halavah or to wipe when finished. Additionally, the really bright technicians have a kink somewhere and either ride fast bikes, fly planes, collect poisonous snakes, chase women (or men), are super religious or super atheist, or live in filth that would rival the ghettos of Babylon.

So, being competent (but not brilliant) and with a good record that stretches back 35 years, I began to collect rejection slips from the job market. After contacting many electronic firms, I can say, without false modesty, that my resumes have entered the finest companies in the state and exited in a dumpster.

Interesting results of the experience: Technical jobs come in four categories. First, the standard technician (tv, audio, two-way, industrial) can make $135 to $175 in forty hours but

must climb towers, pull stubborn coax through conduits, pull control cables under trucks with greasy dirt falling in his face, and repair his supervisor's stereo on his day off. The next step is the experienced technician of 10 to 20 years who makes $200 to $275 a week and has majored in the local technology of his company while taking a healthy minor in its politics. The $275 to $400 slot is filled with Phi Beta Kappa double-Es who are willing to work 15 hours a day and will relocate in Nome, Rome, or Khomeini's home.

Above $400 a week is reserved for a unique group of technicians who must be led to work, told when to breathe and how, wound up in the morning and pointed toward their simple tasks, and escorted to the john when they begin to wear a pained expression, wave their arms aimlessly, and grunt urgently. This seeming contradiction of classification is understandable when you realize that the above $400 category is reserved for the boss's kin and buddies, the kin and buddies of his Secretary of Carnal Knowledge, minority groups he is compelled to hire, and individuals skilled in sexual perversion and narrowly specialized in the kissing of feet. Result: many staff positions filled by LPNs (Limited Productivity Nuisances).

A lot of people think I am retired, and, temporarily, they are right. It's like the business that didn't intend to be nonprofit. Strangely, I couldn't find technicians when I was hiring and now, from the other side of the situation, jobs are as scarce as virgins in the brothels of Hong Kong. Uncle Wayne, why are there no tooth fairies, Santas, and jobs for old radio men?

For a moment, accessing the real world, I can answer my own question. Picture, if you will, a large balance scale such as the one held aloft by Blind Justice (sister of Talmage Justice, pickpocket, porn dealer, and CB operator); in the left pan picture a neat stack of attractively wrapped parcels labeled Experience, Morality, Integrity, Imagination, and Good Record, which represent the offerings I make to the labor market. In the other pan imagine a dimunitive box labeled simply "54 *and* choosy." Now, to complete the picture, imagine the left pan with its burden of many boxes high in the air while the right pan with its single box is flat on the ground, heavy as neutronium from a dwarf star.

There are several options for a rejected technician: I could join IRTRTFSFMALAIPT, or "I reserve the right to feel sorry for myself as long as I pay taxes." Feeling sorry for myself is a valley I like to visit, but I don't want to live there. Another option is to run away with the fat lady across the street who makes obscene gestures at me from her front window, a result of identifying me with the phallic-symbol antennas on my old Ford. But if I can't afford the tastes of my little cute present wife, how can I afford a king-sized one? Besides, summer is coming on and poverty precludes either air conditioning or Arrid, both necessary when living with a blimp. So I stay put with my little cute XYL who has geography like Dolly Parton, cooks like a French chef, and thinks hams are cute.

While pondering these alternatives the other day, a still, quiet voice said, "Well, isn't this what you wanted—freedom from pressure?" I said, "Yes." The still quiet voice said, "Why not be satisfied?" I said, "Say, who are you, still, quiet voice? Where is your QTH. What mode? FM, SSB, or AM?" And the voice said, "I am the Spirit of Things Put Off, Sotpo to you, fellow." And I said, "So send me a resume, yet," and it said, "I am all the great books you were going to write but flunked senior English ogling at Theresa Higgens low neckline. I am all the splendid music you were going to write but didn't know your A flat from first base. I am all the marvelous inventions you were going to birth, anti-gravity, fusion power, humanoid robots, a decent domestic automobile. I am all these things you neglected while you were rag-chewing on 3930. I am all the businesses you were going to start, but found that mongoloids scored better on management skills. I am..."

"Spare me, spirit," I said. "I am indeed guilty of all you say, and more. But don't tell me what I really am."

Relentlessly the spirit continued, "You are," it thundered, if indeed a still quiet voice can thunder, "You are a tinker."

So I replied, as did Abou ben Adhem when waking from his dream, "Shade, I dig thee not, for thou hast come so close to the truth that I must now close my ears. A human trait, I am afraid."

I told the spirit to split and pondered this revelation. It was true: With all my good traits, I am a tinker and, as such, have probably tinkered my way into a tough situation—unemployment.

Warn your readers, Wayne—a good job is hard to find.

I hope this letter will repay you for the many fine editorials over the years. I feel a little indebted for the good thoughts you share with us.

John Townsend
Wilson NC

John, you have been caught up in the fruitless job-hunting syndrome. It is all too easy to do, spurred on by the stupid system set up by the government employment service (and most firms), which thinks in terms of jobs they have open. The middle-aged person has a difficult time breaking through the usual personnel departments. They don't want youngsters because they have neither the specific needed training nor the experience in how to work. And older people are not appreciated because their training is seldom exactly what is wanted and they have a strong tendency to want to do what they already know how to do, whether it is really appropriate or not in their new job.

Rather than fight this situation, I would suggest not even trying to find a job opening. Rather, you decide what it is you are best at doing. Then you figure what firm might be able to use your abilities and talents. The next step is to do some detective work and find out what the company needs... what things are not being done for them that would help. Then you can go in and show how you can benefit them if they create the job you want to fill. It is far easier and better to create a job which calls for your abilities than to try to find the open job which fits you.

To give you an idea of this, let me say that almost without exception when I get letters asking for work, they always are wanting to know what jobs I have open. Never do they write and tell me that if I hire them they will be able to do thus and so for me, a job which will easily pay for itself in added income or savings to the firm.

My publishing firm is growing and I have a serious need for a lot of new people. For example, at this writing I need an experienced PR man, an ad manager to create and produce our in-house ads, ad salesmen for the magazines, a DP manager, a general manager, and a statistical department manager to get data and prepare reports for the computer industry which we would sell. I need several more people to work in our book department, some for the two new magazines we will be starting this year, a couple of electronic draftsmen, a good photographer to help us prepare our covers, people with video experience to help us prepare video training programs, more staffers for 80, which is growing incredibly, people to help us get amateur radio growing again as we did ten years ago, programmers to help us convert programs from one computer system to another, more staffers for Instant Software which has a projected 500% growth over the next year, marketing people, programmers to write in-house needed programs, technicians to keep our computer equipment working and set up new systems, lab people to work on prototypes of new equipment for articles and for industry, teachers to help train our people in all phases of publishing and computing, school administrators to help us found a college of computing, a financial advisor to help us pay for all this... and so on.

Jobs? I've got plenty, if I can find the people. And I think we can provide a lot of benefit by this growth. A school to teach computing would help the micro industry to grow. It would also help American computer firms compete with Japan. An electronic school would also help American industry to compete with Japan. A growth of Instant Software in the international markets could bring millions or even billions of dollars to the U.S. as this market grows.

Getting amateur radio into a strong growth mode, which I am convinced we could do if I had a few enthusiastic people to help me, might even reverse the technological advantages that

Japan has over America at present. There are so many fantastic possibilities for amateur radio over the next few years that it is incredible that we are just standing still, rag-chewing and working DX as usual instead of getting ourselves busy with inventing the next generation of ham gear...and bringing in hundreds of thousands of new hams. We can do it, if we decide it is important. I will be delighted to help...but I sure can't do it alone.

Does that answer you, John?—Wayne.

FACE THE WALL

The Wayne Green view of the ARRL makes a lot more sense since the Don Miller fiasco. I never did find out the real reasons behind this mess, only that Dannals and Baldwin appeared to be afraid of him. As I suppose you have detected, many of us in Indiana consider Don Miller a giant, as a man, a ham, and an engineer. He has helped scores of people get started. Many ATVers and slow scanners have received good advice from Don. He has the delightful facility of being able to deal with skilled technical people at their level of understanding and also help some rank beginner grasp the mysteries of Ohm's Law without putting him down. I contributed to the ARRL building fund and sent in a check for the WARC fund. However, after this distasteful display of power politics on Don Miller, I have turned my ARRL Life Membership plaque to face the wall.

Fair-weather friend.—Wayne.

YES ON CW

Just dropping a line to say hi and keep up the good work. I may not agree with all of your comments and opinions, but I keep an open mind to them. I can always change.

One of the things bugging me lately is the outcry for eliminating the CW requirements for amateur licensing. I cast my vote to keep CW as a requirement for *all* amateur license classes.

For those who wish to get rid of the CW, I ask this: Just why do you wish to get rid of the CW requirement? Is it so someone you know can get on amateur radio? Is this "someone" a person who shows no interest in learning CW? I can't buy the "I can't learn" line. I had all sorts of problems learning CW, and still do. I am at about 16 wpm now, slowly working up to 22.

If that is your basis for eliminating CW, get on your feet and teach the code. If you have to, learn it well yourself. Teaching a class will do wonders for your CW, as well as theory. It is easy to sit back and complain about how hard it is to get people interested in our hobby, but to get out and do something about it is not so easy. I have taught one class, onboard the Coast Guard Cutter *Sherman*, while on patrol in Alaska (sort of a captive class!). The schedule we had and my transfer did not allow me to see the people in the class to their Novice, but I did get one person to get his General (N6DDF). I realize one is not enough, but it is a start. So, instead of complaining about the code, go and teach it. I find very few people with General class or above who hate the code to the point of wanting it eliminated.

Rick Malnhart WB3EXR/6
San Francisco CA

HAM SCHOLARSHIPS

The Foundation for Amateur Radio, Inc., a non-profit organization with its headquarters in Washington DC, plans to award eight scholarships for the academic year 1981-82. All amateurs holding a license of at least the FCC General class or equivalent can compete for one or more of the awards if they plan to pursue a full-time course of studies beyond high school and are enrolled or have been accepted for enrollment in an accredited university, college, or technical school. The scholarship awards range from $300 to $900, with preference given in some of them to residents of various areas.

Additional information and application forms can be requested by a letter or postcard, postmarked prior to May 31, 1981, from: FAR Scholarships, 8101 Hampden Lane, Bethesda MD 20014.

The Foundation is devoted exclusively to promoting the interests of amateur radio and to scientific, literary, and educational pursuits that advance the purposes of amateur radio.

Foundation for Amateur Radio
Washington DC

A NEW PROPOSAL

This letter is in response to the appeal in the December issue of *73* for a code-free licensing proposal. I have been a subscriber to *73* for a few years now and have enjoyed and kept every issue and have built dozens of projects from your construction articles.

If there ever was a victim of the Incentive Licensing plan, I am one. I built my first broadcast band receiver from instructions in a Cub Scout handbook at age 9 in 1958. Over the next few years, I followed my new hobby through *Popular Electronics* and borrowed electronics books (I had not heard of *73* until the late 1970s). In the early 1960s, I met my first amateur, the father of a school classmate. I'll never forget being mesmerized while listening to him talk to the end of the universe (to me), some foreign country called Argentina.

I began visiting the father more than my classmate and began studying to get my license, but a strange thing happened to my amateur friend. Something new he called Incentive Licensing had just been approved, and he went on and on about everything that had been lost and how some of his amateur friends couldn't operate as before. I never did quite understand what he was talking about until I subscribed to *73*. He lost considerable interest in his station and turned more and more to public and Civil Defense type weather radar and police communications. I quit going over so much, and I soon moved to Kansas City where I built my first three-band tube receiver from a kit I bought at a local store I had been using as a mail-order house when I lived out of state. B/A had all kinds of electronic goodies, including my favorite device at the time, the CK722. It is hard for me to realize that in the last 22 years of my life, I have experimented with everything from blue razor blades and a pencil lead for a detector through tubes and now microprocessors and am still just 31 years old.

I have started but never received my amateur's license for almost 20 years now, all because of the code requirements on the exam. I never had the feeling of mystique or curiosity about the Morse code and never saw any need for it, as voice made for a more personal contact and teletype was a perfect form of data-coded messages, not to mention the ASCII of late.

I feel that without the code requirement, I could have become a radio amateur long ago, and by now would know the code and could have possibly helped with development of some form of communication through the amateur bands. Instead, I teach basic electronics and kit building at my daughter's school through a community education program that pays me less than $8.00 a course, but is worth a million dollars when I see the kids' eyes light up when they turn the switch on and their first hand-made project works.

My proposal for a code-free licensing program would be to select some band or bands where no commercially available rigs are built, making admission to the band possible only through building or altering equipment that is available on a nearby band. FCC-type theory and rules tests should be used, but not even a code recognition test. This would defeat the point, as code recognition is about 5 wpm, which can get you a Tech license after taking the General theory test now.

Have a small portion of each band code only, and this portion of the band would be the only portion of the band where General class or above incentive ticket holders could use the otherwise closed band. This would give the non-coders a desire to try to learn the code to contact needed areas and possibly to upgrade to General or higher tickets later on. Power should be limited to 250 Watts or less, and all forms of emissions could be used or leave several small bands with one or two emission forms in each.

Now I realize that this proposal is a little offbeat, but I feel that the basic idea could be used to form a new class of electronic experimenter amateurs that would more than likely

learn the code and upgrade much faster and in greater numbers than what we have now.

I don't know whether or not we should keep the present form of licensing also so that non-electronically-inclined people can memorize the theory and practice in groups until they become programmed to take and pass their incentive plan and become appliance operators. These people don't know the difference between a microprocessor and an op amp; maybe so, we could always use a few more good net controllers. If you don't believe this, listen in on some of the "technical" discussions on the air, and listen to the cries for help on simple modifications to modern-day CB rigs to go onto 10 meters to enjoy an almost vacant band.

I've read letters condemning CBers in your letters column, and then tuned in on a DX contest only to hear the same CB type of operators, only on legal amateur bands with amateur call letters, full FCC support, and League encouragement. There is no wonder that the amateur ranks are falling; after all, so did the CBers. It is too easy to just buy a rig, plug it in, and know nothing about how it works or even how to make simple repairs or modifications.

I have the *73* 5 wpm tape and the 6+ tape and have loaned them to people that express an interest in amateur radio. I even helped a man at work with his theory so that now he is an amateur. The main thing is, he is starting (because of my insistence) to experiment with kits so that now he knows the difference between a diode and a resistor. He didn't have to know it to get his ticket, he just had to know the code and a few rules. Is this the way to keep the undesirables out of the ranks of radio amateurs and off the air? Somehow I think it would be better to build your way up to be an amateur instead of memorizing the present system.

J. Olsen
St. Louis MO

Olsen... no clickee, no tickee. —Wayne.

ANY YO-YO

With regard to the letter from Verle D. Francis WØSZF (March, 1981): Just wait a minute! Mr. Francis "proposes" to allow "code-free, test-free licensees" to use all amateur phone bands with a code test the only requirement for CW operation. I think that no regulations is carrying deregulation a bit far.

I also suggest that if my wife, who is about as technically competent as a flashlight, can earn, yes, earn, her Technician class license (that's the General written test, group), then any yo-yo can, Mr. Francis included.

Bill Hocutt KC4P
Birmingham AL

Right, Bill; let's go to Novice at 50 wpm and see if we don't get a better class of ham.—Wayne.

LIKES THE PRICES

I, too, dislike advertisements which fail to mention an item's price, and as much as possible I refuse to buy anything from a manufacturer or distributor who is so ashamed of his prices that he will not print them. You, as editor of the amateur radio magazine with the most advertising copy, could do all amateurs a great service by refusing ad copy which didn't contain prices.

Also, you have been singing the praises of Casio watches in recent issues. I own a Casio F-80 which I bought in September. Two months later, several functions failed. I returned the watch for in-warranty service to the manufacturer's service center. I received the watch back yesterday, well scratched, a prompt 83 days after I sent it for repairs.

Blair Bates K3YD
Hazleton PA

Okay, phooey on Casio.—Wayne.

CALL FOR PAPERS

For the past 26 years we have held an amateur VHF conference at Western Michigan University. It started when Emeriti Professor of Physics, Walter Marburger W8CVQ, recognized the need for a radio amateur conference to promote VHF activity.

Through the years we have had some outstanding presentations of new designs and techniques, construction, testing, and the announcements of new products. Ed Tilton W1HDQ ("The World Above 50 MHz"), Doug DeMaw W1CER; Dave Hallock (Collins on FET Front Ends), Dr. D. M. Chen ("Free Space Antennas"), Dr. John Lyons ("Ferrite Antennas"), Dr. J. McMechan ("Two Meter Antenna Systems"), Dr. Gooch ("Three Phase SSB on Two Meters"), Chris Frank (Hallicrafters), Robert Groh (Heathkit "Microprocessors in VHF Transceivers"), Jim Kearman, Tom McMullen, Ted Hartson, Clarke Green, and many others have all contributed. To them we give our thanks.

Now we are endeavoring to go a step further. For the past two years the conference non-amateur attendance has increased while the amateur attendance has decreased. We are now appealing to the practicing radio engineer as well as the amateur who is interested in an educational conference rather than a social swap-and-shop session. We are getting the technical-minded *amateur and* professional rather than "operator-types."

As a university sponsorer, this is as it should be; we would like to raise the quality of the conference and at the same time give young pre-professionals experience in paper presentation. One way to do this is to call for papers. We may still have to invite papers, as we have done in the past, but we still feel that a call for papers to all sectors, both amateurs and other VHFers, will produce some results.

The 27th Annual VHF Conference will be held on Saturday, October 17, 1981, from 2:00-5:00 pm at Western Michigan University, Kalamazoo MI. Papers are invited for the 1981 Annual VHF Conference sponsored by the Electrical Engineering Department. Principal emphasis will be placed on engineering developments applied to radio communication, design, and construction on the frequencies of 30 to 1200 MHz.

Papers are solicited from a wide range of areas including, but not necessarily limited to, those listed below:

- Antennas and Transmission Lines
- Audio Frequency Equipment Used With VHF Transmitters and Receivers
- Beginner and Novice Topics
- Contests and Operating Activities
- Emergency Operation and Gear
- Grounding and Shielding
- Keying, Break-in, and Control Circuits
- Measurements and Test Equipment for VHF
- Mobile and Portable Equipment and Operating
- Picture Transmission and Reception
- Power Supplies
- Propagation
- Receiving
- Recent Equipment/New Apparatus
- Regulations
- RTTY
- Satellites
- Transceivers
- Transmitting

One of the basic purposes of this conference is to provide a maximum opportunity to present findings by those experimenting, designing, constructing, testing, and inquiring into problems and methods applicable to VHF radio.

This is an opportunity for beginning or mature researchers to report their findings to their peers. We especially encourage the unexperienced inquirers to obtain some experience by presenting a paper at our VHF Conference.

Authors wishing to present papers should send a synopsis (typically one or two pages with diagrams) describing the paper to: Dr. Glade Wilcox W9UHF/8, Program Chairman, VHF Conference, Department of Electrical Engineering, Western Michigan University, Kalamazoo MI 49008.

Deadline for submission of synopses is June 30, 1981. Speakers will be notified of acceptance by October 1, 1981. Final drafts may be given to the Chairman the day of the Conference. Awards of papers and the possibility of publication are being explored.

Glade Wilcox W9UHF/8
Kalamazoo MI

Well, Glade, while I'm all for your conference, I suspect that one of the reasons your attendance and participation have been dropping on the ham end has to do with the lack of media attention. Advertising still pays. You don't have to pay for ads for such a conference, just see that some of the more interesting papers are made available for publication. There are thousands of hams who would be interested in some of the material presented at your conferences, but they have no way to get it. I attended a similar conference at the University of New Hampshire and I was dismayed at the

wealth of material presented which never really reached more than the few attending the conference. Pity. Perhaps your letter will bring in some ham response. I suspect that if you were to make arrangements for some of the material to reach us for publication, you'd soon be getting a lot more interest.—Wayne.

FCC COMMISSIONER?

It has occurred to me that there has never been an FCC Commissioner who has been an amateur. We have never had a voice in the inner circle of that agency. As it happens, there will be several appointments to the FCC by June of 1981. I am an amateur as well as a working broadcast engineer. I think I have a feel for both broadcasting and amateurs. In considering who usually occupies those offices on "M" Street, I am reminded of the old Mexican curse —"May your life be filled with lawyers." We need a change from that.

I have communicated my idea to both Senator Tower because he is my Senator and to Senator Goldwater for three reasons. First, he is an amateur; second, he will be Chairman of the Subcommittee on Communications; and third, because I have a special, non-obligatory, relationship with him since in 1964 I was a member of a slate of electors pledged to Goldwater/Miller which was elected in Mississippi. Also, I wrote to both because they are influential members of the Republican Party. As yet, there has been no response, but that is not unusual; they get so much mail.

Perhaps a few letters from your readers on the subject to either or both would bring this idea more forcefully to their attention. Of course, if there are readers who know other persons high in the party, letters to them, too, would help.

While I am putting myself forward, I must, in all honesty, admit that there are others in the broadcasting and amateur fraternity who are more qualified than I. If anyone has others to propose, I would be happy to support them because I feel we should have a voice—mine or another amateur's.

Should anyone want to know where I stand philosophically on the specific issues, amateur or otherwise, facing the FCC, I would be most happy to correspond with them.

G. D. Causey
3641 North 11th Street
Abilene TX 79603

Wrong, GD...we did have a ham commissioner and it was he who got us the Novice license, over the badly wounded body of the ARRL. Up until George Sterling, the ARRL had its own way with the FCC.—Wayne.

VIDEO TRAINING

I've just read your editorial goal of gearing up a quarter-million hams in the near future. I am impressed, and excited. I am a high school chemistry teacher, and I have been looking for some assistance in setting up a ham station at the school.

We have over 500 students, including three active hams, all capable and interested. They all get over three hours a week on Apple II computers, of which we drive eight, with double disk. I believe I can interest at least 10% of these kids to try amateur radio, and surely half of those would get their ticket.

The notion of video training sessions seems to me a godsend. I have had a Technician license for two years, but have not been active enough to consider myself a good model of operation. Having video tapes for training would overcome this problem. I am already familiar with your code tapes, and consider them excellent.

Please let us all know when the video tapes are ready. My check for a course set would be in the next post. Other high school teachers I know would do the same.

Jim McSherry N3AMF
Philadelphia PA

ENJOYS EVERYTHING

I would sure like to see you blast the ARRL contest organization in your Never Say Die editorial.

When a contest is on—for example, the Novice Roundup—all of the Novice band sections are pure QRM, teaching and encouraging complete disregard for courtesy on the air. A *small* portion of the entire Novice/Technician population hogs all parts of the bands and creates havoc for those with skeds, etc.

Why can't contests be limited to a portion of each band where they can enjoy(?) the QRM and know where to find their other contestants? I bet that if you were an official in the ARRL, you would do something like I suggest.

Sel Carlson KA6ERF
Napa CA

No, I'd only make it worse. I happen to enjoy contests, QRM, frustration, aggravation, and such, while not liking skeds.—Wayne.

HAM HELP

I am trying to locate anyone having back issues of *Kilobaud*, *73*, *Ham Radio*, or other similar magazines who would be willing to either donate or sell them to a young Indian ham.

Raj VU2UT is a college student in India, and is very interested in radio and microcomputers. He currently has a 6502-based micro called the Junior Computer, with a 1K RAM made by the publishers of *Elecktor* in Germany. Any information and help for him with this unit would also be appreciated.

H. Christopher Ayers WB7TXY
2914 SW 116th
Seattle WA 98146

I'm looking for paperwork or an actual working model of a digital readout for the HW-101. Thanks.

L.D. Dickerson N4DBS
12453 Northwood Road
Savannah GA 31406

I need a schematic and/or other info on a 450-MHz solid-state transceiver, "Trans-Com" model 940, manufactured by Communications Company, Coral Gables FL (no longer in business). I will pay for a Xerox, etc. Thanks.

Harlan Goodsell W7LTH
70 South 2nd East
Hyrum UT 84319

I need a manual or schematic for an Omron Systems Model 8025 CRT terminal. A photocopy is fine. I will be glad to pay for any copying costs.

Roger Eslick KB4VT
29 Elmora Avenue
Goose Creek SC 29445

I am looking for anyone interested in forming an 1802 users net on 20 meters. Any info, comments, or suggestions about this would be welcomed.

Bernie Murphy
102 McCraney Street
Oakville, Ontario
Canada L6H 1H6

Would someone be willing to help a lad who is working his way through high school as well as helping a widowed mother, younger sister, and brother? An uncle gave a several years subscription to *73* as a birthday present to help future ham exam aspirations, but the lad's hatred of scrounging keeps him quiet on a further wish. If someone has no further use for a set of *Callbooks* (one issue) from last year, these would be gratefully received, as his own homebuilt receiver is in use. In return, postcards or a souvenir of ZL-land, or your requirements, could be sent. Please sent to:

B. Wilson
PO Box 1082
Hamilton, Walkato
New Zealand

I want to thank you for your help in getting a much needed schematic for a frequency counter I have. One week after I received my copy of *73*, I received a letter from Gil Desvernine W2PKZ who offered to copy it for me. Thanks again.

KAHANER REPORT

Larry Kahaner WB2NEL
2301 Cathedral Ave. NW
Washington DC 20008

PLAIN TRUTH ABOUT PLAIN RULES

Highlighting my first column from Washington DC, the center of the empire, is perhaps the most important FCC action since ham radio began. The Commission has chosen amateur radio rules and regulations for plain-language revision. Following the FCC's success with the plain-language rewrite of Citizens Band rules—which, incidentally, changed the name to Personal Radio Service—it decided to continue the process with amateur radio.

The legal stuff happened last year. A notice of proposed rulemaking was adopted by the Commission in November and released the following month. That NPRM laid the groundwork and said, in part, "We chose the Amateur Radio Service rules as our latest plain language revision because the existing rules are unnecessarily complex and difficult to understand. This is especially a problem in the Amateur Radio Service since many of our applicants and licensees are young persons."

Amateurs will benefit from the rewrite in many ways. The darn rules will be written in English, so we can all understand them. In fact, the format will be question and answer. It's not beautiful prose, but it's easy to understand. In addition, some rules will be relaxed, others brought up to date.

First of all, the Service's new name is "Amateur Telecommunications Service." In its own subtle way, the Commission hopes that this will make us think of ourselves as more than just voice and Morse code people. The name change reflects growing interest in digital communications.

Second, good old Part 97 will be divided into four sections: (a) Amateur Radio rules, (b) RACES rules, (c) Amateur Satellite rules, and (d) Standards, for all three.

Now the good part. Most changes are just in wording, altering lawyerese to American. But while the FCC clutched its pen, some deregulation crept in. Here are some bright points.

The FCC proposes eliminating all logging requirements. In its place, you must keep the following when you operate: your license or photocopy, copies of letters in which you informed the FCC of address changes, copy of the Amateur Telecommunications Service rules, any written permission you received from the Commission, and copies of letters from the FCC about your station or operator's license.

Radio District	Group A	Group B	Group C	Group D
0	KIØH	KBØVU	NØCIH	KAØKJK
1	KC1F	KA1NX	N1BIM	KA1GOB
2	KK2H	KB2WU	N2CHL	KA2LHO
3	KC3L	KB3NS	N3BQZ	KA3HAU
4	NJ4C	KC4WP	N4EEF	KA4TJL
5	KO5X	KC5GT	N5CTW	KA5KXS
6	KV6F	KD6QO	N6DYT	KA6OMB

Puerto Rico	NP4E	KP4BZ	NP4BV	WP4BTG

Table 1. Callsigns issued February 1, 1981. Group A = Extras; B = Advanceds; C = Techs and Generals; D = Novices.

For repeaters, you must keep these items: computations for average height above average terrain and external power. For remote control operations, you need: control operators' names, calls, and addresses, block diagram and technical explanation of link, description of measures for shutting down the station if control link fails, and, finally, measures for monitoring transmission frequency.

You must retain these records for your license term.

Not bad. The FCC shows a lot of class with these changes. And not only are the new rules easier to understand, they're easier to read. The old rules were written in super-small type that looked like a cut-rate washing machine warranty. New rules are in typewriter-size type.

The FCC isn't doing this in a vacuum, mind you. If you harbor comments about plain language rules, let the Commission know. You may respond to the proposal by reading the text, or just the parts you're hot about, and letting them know if they're on the right track. Positive comments carry as much weight as negative ones.

For information on how to contact the FCC about Docket PR 80-79 (the PR means Private Radio Bureau, 80 is the year it was written, and 79 means it was the 79th issue from the bureau), call John Johnston at (202)-254-6884. Or you can write him at FCC, Private Radio Bureau, 1919 M St., Washington DC 20554.

Comments are due by June 19. Replies to those comments must be in by August 19. And, if you believe, or your group believes, that the Commission is making a huge mistake and you have some ideas of your own but need more time to get them organized, you may ask for a deadline extension. If the reason is important enough, the FCC will grant extra time.

NO NEW LICENSES FOR CLUBS, SO FORGET IT

On occasion, the FCC will issue statements on subjects that seem to cause a lot of concern or misunderstanding. Sometimes they are just rehashes, sometimes gentle reminders, sometimes clarifications.

The FCC has received loads of queries about new licenses for clubs, military recreation, and RACES stations. Last May, the Commission amended rules pertaining to these stations, and the folks in Washington want you to know they haven't changed their minds. No new licenses for clubs, military recreation, or RACES stations will be issued. Period.

Only renewals or modifications are allowed. However, changing a trustee or club name is considered a modification, and that is allowed. If you still don't believe it or you want to argue, call the Consumer Assistance Staff in Gettysburg PA at (717)-334-9167.

CALLSIGNS: CAN'T SEEM TO GET ENOUGH

In keeping with hams' insatiable hunger for call-letter roulette, the FCC published a chart of issued call letters. Callsigns listed in Table 1 are the *last* ones mailed, as of February 1.

MARINE GRAB FOR 220?

Contrary to rumors floating around in ham circles, the FCC never seriously considered placing the automated inland waterways communications system in the 220-MHz band. The system, which will be used for ship-to-shore communications only, was slated for 216-220 MHz or 806-890 MHz.

Similar to the proposed cellular mobile-telephone service, the inland waterways service places repeaters all along the Mississippi River and its major tributaries. To contact a boat, you dial a central number and it connects to the repeaters. Instead of the old system of trying to find the marine operator nearest your vessel—and maybe taking several radio calls from various operators—it takes only one dialing. It works the other way, too. Instead of vessels calling the nearest marine operator, the crew simply dials a conventional telephone and the nearest repeater is keyed up. The system also transmits data and facsimile and will be used mostly by commercial vessels such as barges and tugs.

The FCC decided to allot 216-220 MHz for the service.

WELL, THERE GOES THE NEIGHBORHOOD

Whether the FCC is definitely moving across the Potomac to Rosslyn VA is still a tough one to call. In the long run, the FCC could save money, and instead of being spread out over three downtown buildings, they would be in one. Amid all the controversy and alleged under-the-table dealings, Congress is balking at the move because it's never happy when federal agencies leave the District.

ONE OF THE OK GUYS LEAVES

Charles Ferris, FCC top banana, retired last month. Heavy-duty broadcasters didn't like Ferris because of his yearning for broadcast deregulation.

Under Ferris' rule, low-power TV was proposed, cable companies flourished, and satellite superstations grew. Networks, which for years had the only wheel in town, wanted to keep it spinning their way. The more players in the game, the less each player gets. And the big guys couldn't handle it.

At presstime, his replacement wasn't named, but smart money is on Mark Fowler, a communications lawyer. To be an FCC commissioner (the chairman is also a commissioner), you don't need a high-school diploma or any discernible skills. It's strictly by presidential appointment. Even money won't help you get the job unless it finds its way into the right politician's pocket.

FCC

Changes in Procedures for Approval of Proposed Antenna Structures in the Amateur Radio Service

AGENCY: Federal Communications Commission.

ACTION: Final rule.

SUMMARY: The Commission is amending Parts 17 and 97 of its rules to simplify its procedure for processing requests for approval of Amateur Radio station antenna structures with regard to possible hazard to air navigation. The Commission is also making an editorial change to conform a rule section in Part 97 to a parallel rule section in Part 17.

EFFECTIVE DATE: The amendments being adopted are subject to the clearance of reporting requirements by the General Accounting Office, the effective date of this action will be announced by public notice in the near future.

ADDRESS: Federal Communications Commission, Washington, D.C. 20554.

FOR FURTHER INFORMATION CONTACT: John B. Johnston, Private Radio Bureau (202) 632–4964.

SUPPLEMENTARY INFORMATION:

In the matter of changes in procedures for approval of proposed antenna structures in the Amateur Radio Service.

Adopted: January 6, 1981.

Released: January 21, 1981.

By the Commission: Chairman Ferris absent.

1. Section 303(q) of the Communications Act of 1934, as amended, provides that the Commission shall "have authority to require the painting and/or illumination of radio towers if and when in its judgment * * * there is a reasonable possibility that they may constitute a menace to air navigation." Part 17 of the Commission's rules sets forth criteria and procedures by which the Commission exercises this authority.

2. In the Amateur Radio Service, an antenna structure which would exceed certain height limitations (set forth in § 97.45) may not be erected or used unless prior approval by the Commission has been obtained. Currently, amateur radio operators obtain this approval by filing FCC Forms 610 and 714 with the Commission and FAA Form 7460–1 with the FAA. These requests for antenna structure approval are processed partially at the Private Radio Bureau licensing facility in Gettysburg, Pa. and partially at FOB Antenna Survey Branch in Washington, D.C.

3. We are amending Parts 17 and 97 of our rules to allow amateur radio operators to file a single form to obtain approval of proposed antenna structures, instead of the two forms (610 and 714) currently required. By this action, we are simplifying the antenna approval process for both Amateur Radio licensees and the Commission. All antenna structure approval requests filed on the new form will be processed entirely in Washington, D.C. by the Antenna Survey Branch.

4. We are also amending paragraph (a) of § 97.45 to agree with the current wording of § 17.7 of the rules. Since Amateur Radio Service licensees are subject to the provisions of Part 17, this amendment is editorial in nature and imposes no new requirements.

5. Since the rule changes herein ordered concern the Commission's antenna approval procedures and practices, and also involve an editorial amendment to conform Part 97 Amateur Radio Service Rules to Part 17 antenna requirements, we are dispensing with the prior notice and public procedure provisions of the Administrative Procedure Act (see 5 U.S.C. 553(b) (A) and (B)). However, as the amendments being adopted are subject to the clearance of reporting requirements by the General Accounting Office, the effective date of this action will be announced by public notice in the near future.

6. For information on these rule changes contact John B. Johnston, (202) 632–4964.

(Secs. 4, 303, 307, 48 Stat., as amended, 1066, 1082, 1083; 47 U.S.C. 154, 303, 307).

Federal Communications Commission.

William J. Tricarico,

Secretary.

Appendix

PART 17—CONSTRUCTION, MARKING, AND LIGHTING OF ANTENNA STRUCTURES

I. Part 17 of Chapter I of Title 47 of the Code of Federal Regulations is amended, as follows:

In § 17.4, paragraph (a) is revised, and a new paragraph (h) is added:

§ 17.4 Commission consideration of proposed antenna structure with respect to possible hazard to air navigation.

(a) Except as provided in paragraph (h) of this section, all applications are reviewed to determine whether there is a requirement that the applicant file a Notice of Proposed Construction or Alteration (FAA Form 7460–1) with the Federal Aviation Administration.

* * * * *

(h) Applications for amateur radio station licenses and RACES station licenses are not reviewed for antenna structure approval. Applicants and licensees in those services may not erect or use an antenna which exceeds the height limitations contained in §§ 17.7 and 17.14 of this chapter unless notice has been filed with both the FAA on FAA Form 7460–1 and with the Commission on FCC Form —— and prior approval by the Commission has been obtained.

PART 97—AMATEUR RADIO SERVICE

II. Part 97 of Chapter I of Title 47 of the Code of Federal Regulations is amended, as follows:

In § 97.45 paragraph (a) introductory text and subparagraph (3) thereof are revised as follows. Also, a new subparagraph (4) is added to paragraph (a).

§ 97.45 Limitations on antenna structures.

(a) Except as provided in paragraph (b) of this section, an antenna for a station in the Amateur Radio Service which exceeds the following height limitations may not be erected or used unless notice has been filed with both the FAA on FAA Form 7460–1 and with the Commission on FCC Form ——, and prior approval by the Commission has been obtained for:

(1) * * *

(2) * * *

(3) When requested by the FAA, any construction or alteration that would be in an instrument approach area (defined in the FAA standards governing instrument approach procedures) and available information indicates it might exceed an obstruction standard of the FAA (§ 17.7(c) of this chapter).

(4) Any construction or alteration on any of the following airports, including heliports (§ 17.7(d) of this chapter).

(i) An airport that is available for public use and is listed in the Airport Directory of the current Airman's Information Manual or in either the Alaska or Pacific Airman's Guide and Chart Supplement.

(ii) An airport under construction, that is the subject of a notice or proposal on file with the Federal Aviation Administration, and except for military airports, it is clearly indicated that the airport will be available for public use.

(iii) An airport that is operated by an armed force of the United States.

LOOKING WEST

from page 138

hope to be able to discuss the important points of the proposed rules in the column the next few months. At this time, everything is just innuendo and rumor except the already well-publicized points. I guess there will be some who say that this latest "bug" in the FCC's eye was caused by the modelers. I doubt it. If there is anything to it, and if amateurs eventually lose R/C privileges on six meters, it will probably be the result of internal FCC policy more than anything else.

Oh, yes, lest I forget: It seems that there are many differing interpretations of Carson's Rule as there are engineers. I suspect that all are correct in some way. Not being an engineer myself, I hazard to venture any further guesses. I learned of the existence of Carson's Rule during the time I was heavily involved in two-meter repeater coordination activities here in the southwest, this during the time we were considering whether to go upright or invert the 15-kHz tertiary channels. When applied, both the definition you give and that utilized by the then SCRA seem applicable. Another result of the bandplan article has been a myriad of interpretations of the aforementioned Carson's Rule. The basic differences are semantic in nature.

Again, Lew, thanks very much for taking the time for writing the detailed letter. As I said in the note of two weeks back, I will endeavor to see that it appears in print.

The last two Looking West columns might be described best as a discourse between two amateurs who have sincere concern for the future of an important amateur band. There is no doubt that our end objectives are the same. We differ only in the way we approach solving the dilemma.

SOCIAL EVENTS

Listings in this column are provided free of charge on a space-available basis. The following information should be included in every announcement: sponsor, event, date, time, place, city, state, admission charge (if any), features, talk-in frequencies, and the name of whom to contact for further information. Announcements must be received two months prior to the month in which the event takes place. They should be sent directly to Editorial Offices, 73 Magazine, Pine Street, Peterborough NH 03458, Attn: Social Events.

SUNNYVALE CA
MAY 1-3

The West Coast UHF Society and Project OSCAR, Inc., will hold the 26th Annual West Coast UHF Conference on May 1-3, 1981, at the Sunnyvale Hilton, 1250 Lakeside Drive, Sunnyvale CA 94086. There will be registration Friday night and a social in the hospitality room. Saturday registration will begin at 8:15 am and be followed by orientation, technical sessions, a barbeque cookout luncheon, prize drawings in the afternoon, and dinner. Saturday night will also include noise figure measurements. Sunday morning will feature a show-and-tell of homebrew projects, as well as antenna measurements tests. Pre-registration is $5.00; cost at the door will be $8.00. For more information or pre-registration send an SASE to West Coast UHF Conference, PO Box 5283, San Mateo CA 94402.

GRAY TN
MAY 2-3

The Bristol Amateur Radio Club, the Johnson City Amateur Radio Association, and the Kingsport Amateur Radio Club will hold their first annual Tri-Cities Hamfest on May 2-3, 1981, at the Appalachian Fairgrounds, north of Johnson City (off Highway 137), Gray TN, from 9:00 am to 5:00 pm on Saturday and from 8:00 am to 4:00 pm on Sunday. The dealer space charge at the door is $30.00 for the weekend for a 10 × 12 space. The dealer charge also includes security and admission for five employees. There are approximately 40 RV spaces with complete hookups renting for $5.00 per night inside the fairgrounds. Motels are available nearby. Dealers can set up anytime after Friday noon or after 6:00 am Saturday and Sunday. Further information can be obtained by writing Mary S. Biggs KA4EXP, Secretary-Treasurer, Tri-Cities Hamfest, PO Box 3682 CRS, Johnson City TN 37601, or phoning either (615)-928-1818 or (615)-282-1711-x380.

GREENVILLE SC
MAY 2-3

The Blue Ridge Amateur Radio Society will hold its annual hamfest on May 2-3, 1981, at the American Legion Fairgrounds, Highway 25 bypass, Greenville SC. On Saturday, FCC exams will be given at Greenville Tech from 10:00 am till 3:00 pm. Other features will include dealer exhibits, inside flea markets, chicken/pork plates, prizes, overnight RV parking, and motel rooms available at the Ramada Inn (1-800-228-2000).

WOODBRIDGE NJ
MAY 2

The DeVry Technical Institute Amateur Radio Club (WA2MDT) will hold its fifth annual amateur radio and computer flea market on May 2, 1981, at DeVry Technical Institute, 479 Green Street, Woodbridge NJ. The flea market will begin at 9:00 am and for those who wish to set up tables, a fee of $3.00 will be charged. Talk-in on 146.520 beginning at 8:00 am. For further information, call Frank Koempel WB2JKU at 634-3460 or Steve Hajducek KA2IFX at 727-5962.

MEADVILLE PA
MAY 2

The seventh annual Northwestern Pennsylvania Hamfest will be held on May 2, 1961, at the Crawford County Fairgrounds, Meadville PA. The gates will open at 8:00 am. Admission is $3.00; children under 12 will be admitted free. Indoor table spaces are $5.00 per space and outdoor car spaces are $2.00. Bring your own tables. Refreshments will be available. Commercial displays are welcome. Talk-in on .04/.64, .81/.21, and .63/.03. For information, write CARS, PO Box 653, Meadville PA 16335, Attention: Hamfest Committee.

LYNCHBURG
MAY 3

The Lynchburg Amateur Radio Club will hold its third annual swapfest at Brookville High School in Lynchburg on Sunday, May 3, beginning at 10:00 am. Tables, food service, and plenty of free parking will be available. Talk-in on 146.01/.61 and 146.52 simplex. For further information, contact Kenneth D. Grimm K4XL, 505 Hayes Dr., Lynchburg VA 24502.

STIRLING NJ
MAY 3

The Tri-County Radio Association will hold its annual indoor hamfest flea market on May 3, 1981, at the Passaic Township Youth Center, Valley Road, Stirling NJ, from 9:00 am to 4:00 pm. A donation is $2.00 and the tables are $5.00. Hot food and refreshments will be served. An Icom IC-2AT will be one of the many door prizes. Talk-in on 147.855/.255 or 146.52. For information, write TCRA, Box 412, Scotch Plains NJ 07076, or call Herb Klawunn W2CHA at (201)-647-3461.

PENNS PARK PA
MAY 3

The Warminster Amateur Radio Club will hold the 7th annual Ham-Mart on Sunday, May 3, 1981, from 9:00 am to 4:00 pm (rain or shine) at a new location, Middleton Grange Fairgrounds, just minutes from I-95 or the Pennsylvania Turnpike on Penns Park Road, Penns Park PA. Featured will be door prizes, plus a grand prize to be drawn at 3:00 pm, a flea market, a free FM Clinic, and an auction. There will be refreshments, rest rooms, and shelter available. Registra-

tion is $3.00 per person, which includes one ticket for door prizes. YLs, XYLs, and children under 14 will be admitted free. Seller (tailgater) spaces are $2.00 (with tables available). Talk-in on 146.52 or WARC 147.69/.09. For additional information, write WARC, PO Box 113, Warminster PA 18974, or call Mark Hinkel WA3QVU at (215)-657-7295.

SULLIVAN IL
MAY 3

The 20th annual Moultrie Amateur Radio Klub Hamfest will be held on May 3, 1981, at the Moultrie County 4-H Center Fairgrounds, located 5 miles east of Sullivan IL, on Cadwell Road. There will be a heated indoor and a large, covered outdoor flea market. There is no charge to vendors. Space is available on a first-come, first-served basis. Talk-in on 146.94 and 146.055/.655. For more information, write MARK, PO Box 327, Mattoon IL 61938.

EAST HARTFORD CT
MAY 3

The Pioneer Valley Radio Association will sponsor its fourth annual flea market on Sunday, May 3, 1981, at a new location in the George Penny High School, East Hartford CT, from 10:00 am to 4:00 pm. The admission donation is $1.00 and tables are $8.50. For advance table reservations or information, contact Arnie K1NFE, PO Drawer M, Plainville CT 06062.

DEERFIELD NH
MAY 9

The Hosstraders will hold their eighth annual tailgate swapfest all day on Saturday, May 9, 1981, at the Deerfield Fairgrounds, Deerfield NH. Admission is $1.00, which includes tailgating and commercial dealers. Profits will benefit the Boston Burn Unit of the Shriners' Hospital for Crippled Children. Last year we donated $2,058.16. Talk-in on .52 and 146.40/147.00. For more information, send an SASE to Joe K1RQG, Star Route, Box 56, Bucksport ME 04416; Norm WA1IVB, RFD Box 28, West Baldwin ME 04091; or Bob W1GWU, Walton Road, Seabrook NH 03874.

CEDARBURG WI
MAY 9

The Ozaukee Radio Club will hold its annual indoor swapfest on Saturday, May 9, 1981, at the Cedarburg Community Center Gym, Washington Avenue, Cedarburg WI. Cedarburg is 22 miles north of Milwaukee. Doors will open at 8:00 am for the general public and 7:00 am for table setup. Admission is $2.00 in advance and $3.00 at the door. Tables are $3.00 per 6 feet (advance purchases are recommended). Features will include door prizes, food, refreshments, and free parking. Talk-in on 146.37/.97 and 146.52. For more information or advance tickets, send an SASE to Ozaukee Radio Club, PO Box 13, Port Washington WI 53074.

CADILLAC MI
MAY 16

The Wexaukee Amateur Radio Association will hold its 21st annual Swap Shop & Eyeball QSO on Saturday, May 16, 1981, at the Michigan National Guard Armory, Haynes Street, Cadillac MI from 9:00 am to 4:00 pm. Admission is $2.00, and 8-foot tables are $3.00. There will be a grand prize, a Yaesu FT-207R hand-held transceiver, plus many smaller prizes. A lunch counter and parking will be available, as well as camping in the immediate area, and free transportation for flying to and from the Wexford County Airport. Talk-in on 146.37/.97. For further information, contact the Wexaukee Amateur Radio Association, Box 163, Cadillac MI 49601.

SILOAM SPRINGS AR
MAY 16

The Northwest Arkansas Amateur Radio Club, Inc., will hold its 1st annual hamfest/swapmeet on Saturday, May 16, 1981, at the Siloam Springs Community Building, Siloam Springs AR, from 8:00 am to 5:00 pm. It will be all indoors and commercial exhibitors' tables are free. Flea market tables are $2.00 each. Doors open at 6:00 am for setting up tables. Great prizes will be available, including a TS-830. There will be refreshments and free parking. Talk-in on .16/.76 or .52 simplex. For more information, send an SASE to Bob Harmon W5SEP, Route 1, Box 13E, Elkins AR 72727.

KEY WEST FL
MAY 16-17

The annual Conchfest will be held on May 16-17, 1981, in Key West FL. Activities will include an all-you-can-eat conch dinner on Saturday night, a social hour, a free conch train tour, a free conch trolley ride, a conch shell blowing contest, and prizes. A discount book for many Key West attractions will be available. Conchfest tickets are $25.00 per person, tickets for harmonics (12 and under) are $15.00 each, and rooms at the Sportsmen's Inn are $34.00. Tickets include Saturday night dinner, three free drinks at the social hour, the Sunday morning continental breakfast at the Sportsmen's Inn, and the discount book. For more information and advance reservations, write Key West Amateur Radio Club, Inc., PO Box 2371, Key West FL 33040.

DURHAM NC
MAY 16-17

The Durham FM Association will hold its Durhamfest '81 on May 16-17, 1981, at South

Square Mall, Durham NC. There will be a large covered flea market, and rental tables will be available. General admission is $3.00 with no additional charges for tailgaters or dealers' spaces. On May 17 there will be ladies' bingo. Talk-in on 147.825/.225, 146.52, and 222.34/223.94. For further information and advance tickets, write Durham FM Association, PO Box 8651, Durham NC 27707.

EASTON MD
MAY 17

The seventh annual Easton Amateur Radio Society hamfest will be held on May 17, 1981, rain or shine, from 10:00 am to 4:00 pm at the Easton Senior High School cafetorium on Route 50, just south of Easton at mile marker 66. Donation is $2.00, with an additional $2.00 for tables or tailgaters. Talk-in on .52 simplex and 146.445/147.045 on the repeater in Easton. For more details, write R. C. Thompson KA3BKW, PO Box 1473, Easton MD 21601, or Easton Amateur Radio Society, Inc., Box 781, Easton MD 21601.

EVANSVILLE IN
MAY 17

The Tri-State Amateur Radio Society will hold its annual hamfest on May 17, 1981, at the Vanderburgh County 4-H Center, Evansville IN. There will be an air-conditioned indoor flea market, and over 70 indoor tables will be available. Adult admission is $1.00. An outdoor flea market will also be featured. Talk-in on 147.75/.15 or 146.19/.79. For further information, contact Tom WA9QDZ, 2851 Wayside Drive, Evansville IN 47711.

ATHENS OH
MAY 17

The Athens County Amateur Radio Association's annual hamfest will be held on Sunday, May 17, 1981, at the Athens City Recreation Center, East State Street, Athens OH, from 8:00 am to 4:00 pm. Tickets are $1.00 in advance, $1.50 at the gate. There will be a free flea market for electronics-related items in a large outdoor, paved area. Some indoor space will be available on a first-come, first-served basis. Setup will be at 7:00 am. Food and plenty of free parking will be available. Several restaurants and a recreation area are adjacent to the Athens Mall. Talk-in on .34/.94. For further information, send an SASE to ACARA, c/o Jeff White WD8OXK, PO Box 767, Athens OH 45701, or telephone Joe Foilrod WB8DOD at (614)-797-4874.

WEBSTER MA
MAY 17

The Eastern Connecticut Amateur Radio Association will hold its seventh annual hamfest and flea market on May 17, 1981, rain or shine, at Point Breeze Restaurant, Webster MA. For more information, contact Richard Spahl K1SYI, Lake Parkway, Webster MA 01570, or call (617)-943-4420 after 8:00 pm.

BOULDER CO
MAY 17

The Rocky Mountain VHF Society will hold the annual spring hamfest on Sunday, May 17, 1981, from 9:00 am to 4:00 pm, rain or shine, at the Boulder National Guard Armory, 4750 North Broadway, Boulder CO. The admission donation will be $2.00 per family, and there is no seller's charge. Setup starts at 8:30 am and we suggest you bring your own table. The door prizes will include a synthesized FM transceiver, and extra raffle tickets will be available. In addition to the big ham swap, there will be formal technical demonstrations and seminars, covering topics such as fast-scan ham TV, microwaves, satellite communications, etc. Food and drink will be available. Talk-in on 146.16/.76 and 146.52. For more information, contact Richard Ferguson KA0DXM, 1150 Albion Road, Boulder CO 80303, or phone (303)-499-2871.

WABASH IN
MAY 17

The Wabash County Amateur Radio Club will hold its 13th annual hamfest on Sunday, May 17, 1981, from 6:00 am until 3:00 pm at the Wabash County 4-H Fairgrounds, Wabash IN. Admission will be $3.00 at the gate or $2.50 in advance. There will be plenty of food and parking available, as well as camping space for Saturday night. Talk-in on 7.63/.03 or .52. For tickets or more info, send an SASE to Dave Spangler N9ADO, 45 Grant Street, Wabash IN 46992.

MARSHALL MO
MAY 17

The Indian Foothills Amateur Radio Club will hold its 6th annual hamfest on May 17, 1981, at the Saline County Fairgrounds building, Marshall MO. Tickets are $2.00 each or 3 for $5.00 at the door, or 4 for $5.00 in advance. There is no charge for tables but reservations are requested. Registration will be at 8:00 am and coffee and breakfast rolls will be served from 8:00 am to 10:00 am. Lunch (all you can eat) will be at 11:30 am and the drawing will be held at 2:30 pm (with a first prize of an Icom IC-2AT). Talk-in on .52, .28/.88, and 147.84/.24. For information and advanced tickets, contact Phyllis French W0WIE, Route 4, Box 168, Sedalia MO 65301, or phone (816)-826-8319 after 5:00 pm or K0BVB at (816)-886-2837.

ISLIP LI NY
MAY 17

The Long Island Mobile Amateur Radio Club, Inc., will hold the ARRL Hamfair '81 on May 17, 1981 (rain date June 7th), at the Islip Speedway, 2 blocks south on Islip Avenue (Rte. 111) or Exit 56. General admission is $2.00 for all hams, with family members admitted free. Each exhibitor space is $4.00 and admits one person. Features include the LIMRUN at 11:00 am, over 350 computer and ham exhibitors along with general merchandise and swap 'n shop, food and refreshments, and many awards presented throughout the day. Talk-in on 146.25/.85. For more information, call Sid Wolin K2LJH at (516)-379-2861, or Hank Wener WB2ALW at (516)-484-4322 in the evening.

PITTSBURGH PA
MAY 17

The 27th annual Breeze Shooters Hamfest will be held on May 17, 1981, from noon to 5:00 pm at the White Swan Park, Rte. 60 (Parkway West), near the Greater Pittsburgh International Airport, Pittsburgh PA. Registration is $2.00, or three for $5.00. Activities will include a large free flea market, prizes, contests, and a family amusement park. Sheltered tables for vendors are available by advance registration only. Talk-in on .28/.88 or 29.0. For further information, contact Don Myslewski K3CHD, 359 McMahon Road, North Huntingdon PA 15642.

NEWPORT RI
MAY 18

The Newport County Radio Club will hold an auction on Monday, May 18, 1981, at 7:00 pm at the club headquarters in the Seamen's Church Institute Building, 18 Market Square, Newport RI. Talk-in on 147.96/.36.

GASTONIA NC
MAY 23

The Gastonia Amateur Radio Society will hold its fifth annual hamfest on Saturday, May 23, 1981, beginning at 9:00 am, at Karyae Park near Gastonia NC. Pre-registration is $2.50 and tickets at the gate are $3.00. Flea market tables are $5.00 each, with a limit of 4. Flea market as well as rag-chew space will be provided. Tailgating is invited. Exhibitors may set up at 7:00 am. Features include refreshments, a grand prize of a Kenwood TS-520SE (plus other prizes), a bingo hour, plus plenty of parking facilities. Talk-in on 147.72/147.12 and 146.52 simplex. For more information, contact the hamfest chairman, Glenn Varner W4PBQ, 1322 Poston Circle, Gastonia NC 28052, or phone (704)-866-8339.

HAMBURG PA
MAY 24

The Reading Radio Club will hold its third annual hamfest on May 24, 1981, rain or shine, at the Hamburg Field House, Pine Street, Hamburg PA. Adult admission is a $2.00 donation. ST PAUL MN
MAY 30

The North Area Repeater Association will sponsor a swapfest and exposition for radio amateurs and computer hobbyists on May 30, 1981, at the Minnesota State Fairgrounds, St. Paul MN. There will be free overnight parking for self-contained campers on May 29th. Exhibits, booths, and prizes will be featured. Admission is $3.00. For information or reservations, write Amateur Fair, PO Box 30054, St. Paul MN 55175.

COLUMBIA SC
MAY 30

The Columbia Amateur Radio Club will sponsor the 4th annual Columbia Hamfest on Saturday, May 30, 1981, at Midlands Tec College, Beltline Campus, Co-

lumbia SC. Doors will open at 9:00 am. There will be plenty of room available for the outdoor flea market in the south parking lot. Dealer displays will be indoors, and the food stand will be on campus. Talk-in on .34/.94. For more information, please contact Mr. Bob Burks KC4LB, CARC, PO Box 5802, Columbia SC 29250, or phone (803)-776-9054.

GORHAM ME
MAY 30

The Portland Amateur Wireless Association and the University of Southern Maine/Gorham will hold an amateur radio flea market on May 30, 1981, from 8:00 am to 5:00 pm at the gym and the parking lot (inside if it rains) at the University of Southern Maine, Gorham ME campus. The cost is $1.00 per person. Food and drinks will be available. For more information, contact John A. Taylor N1SD, 44 Mitton Street, Portland ME 04102, or phone (207)-773-2651.

HARTWELL GA
MAY 30-31

The Anderson, Hartwell, and Toccoa Amateur Radio Clubs will hold the 3rd annual Lake Hartwell Hamfest on May 30-31, 1981, at the Lake Hartwell Group Camp, located on Highway 29, 4 miles north of Hartwell GA. Features include free admission, free camping, and free flea-market spaces. Activites include live musical entertainment, tours of Lake Hartwell dam and power house, a left-footed CW contest, a horseshoe tournament, and many other activities for the whole family. Fishing, swimming, and camping are available at the site. The campgrounds opens at 6:00 pm Friday and the main prize drawing will be held at 2:00 pm Sunday. Talk-in will be on 146.19/.79, 147.93/.33, and 146.895/.295. For further information, contact Carl Davis KY4T, 203 College Avenue, Hartwell GA 30643.

RANCHO CORDOVA CA
MAY 31

The North Hills Radio Club will hold its 9th annual Sacramento Valley Radio Ham Swap on Sunday, May 31, 1961, from 9:00 am to 3:00 pm at the Machinists' Hall, 3081 Sunrise Boulevard, Rancho Cordova CA. There will be table rentals, food, club auctions, and prizes. Admission is free. Talk-in on 144.59/145.19 and 223.18/224.78. For further information, contact NHRC, W6BWZ, PO Box 41635, Sacramento CA 95841.

WEST FRIENDSHIP MD
MAY 31

The Maryland FM Association will hold its annual hamfest/computer show on Sunday, May 31, 1981, at the Howard County Fairgrounds, West Friendship MD, from 8:00 am to 4:00 pm. Admission is a $3.00 donation, tailgating is $2.00, and tables are $6.00. Talk-in on 146.16/.76. For more information, write MFMA, c/o Heru Walmsley, Post Office, Harmans MD, or phone (301)-766-3545.

TRENTON TN
MAY 31

The Humboldt Amateur Radio Club will hold its annual hamfest on Sunday, May 31, 1981, at Shady Acres City Park, Trenton TN. Featured will be a flea market, prizes, ladies' activities, and light lunches. There are restaurants available nearby; also available will be overnight parking for a limited number of RVs. There is no admission charge. Talk-in on 146.37/.97. For further information, contact Ed Holmes W4IGW, 501 N. 18 Avenue, Humboldt TN 38343

GRAND RAPIDS MI
JUN 6

The Independent Repeater Association will hold the Grand Rapids Spring Swap & Shop on Saturday, June 6, 1981, at the National Guard Armory, 44th Street, just 1/4 mile west of US 131. There will be door prizes, dealers, food, and indoor swap area, forums, and trunk sales. Reserved dealer area is available. Doors open at 8:00 am. Tickets are $2.00 and indoor tables are $5.00. Talk-in on 147.765. For further information, contact David Jenista WD8NZZ, 437 Airview SE, Wyoming MI 49508.

MANASSAS VA
JUN 7

The Ole Virginia Hams Amateur Radio Club, Inc., will hold its annual Manassas Hamfest on Sunday, June 7, 1981, at the Prince William County Fairgrounds, Route 234, Manassas VA. Booths are available. Admission is $3.00, children under 12 will be admitted free, and tailgaters will be charged an additional $2.00. Features will include a ladies' program, indoor and outdoor exhibit areas, a full breakfast and lunch, children's entertainment, CW proficiency awards, and QSL bureaus. Talk-in on 146.37/146.97 repeater (W1CRO) and 146.52 simplex. For booth reservations, contact Joseph A. Schlatter K4FPT, Ole Virginia Hams ARC, Inc., PO Box 1255, Manassas VA 22110.

CHELSEA MI
JUN 7

The Chelsea Swap and Shop will be held on Sunday, June 7, 1981, at the Chelsea Fairgrounds, Chelsea MI. Gates will open for sellers at 5:00 am and for the public from 8:00 am until 2:00 pm. Admission is $1.50 in advance or $2.00 at the gate. Children under 12 and non-ham spouses are admitted free. Talk-in on 146.52 simplex and the 147.855 Chelsea repeater. For more info, write to William Altenberndt, 3132 Timberline, Jackson MI 49201.

SHARONVILLE OH
JUN 12

The Hamilton County Amateur Radio Public Service Corp. will sponsor the first annual Cincinnati ARRL '81 Convention at the Scarlet Oaks Vocational Campus, Sharonville OH, on Saturday, June 12, 1981. This event will *not* be replacing the Cincinnati Hamfest which will be held on Sunday, September 20, 1981, at the usual location at Stricker's Grove, Ross OH.

MIDLAND MI
JUN 13

The Central Michigan Amateur Repeater Association will hold its seventh annual hamfest on June 13, 1981, from 8:00 am to 2:00 pm at its new location in the "Great Hall" in the Valley Plaza complex, just off US Rte. 10 in Midland, Michigan. Tickets are $3.00; children under 12 will be admitted free. Tables are available for $6.00 ($3.00 for half a table). Trunk sales will be $2.00 in a designated area. There will be plenty of free parking. The Valley Plaza Complex offers motel accommodations, RV hookups, swimming, dining, a bowling alley, theaters, and a picnic area. The major prize drawing will be at 1:30 (for an HT); there will be hourly drawings for other prizes. Videotapes of the Saturn fly-by will be shown. Talk-in will be on 146.13/.73 and 146.52 simplex. For information, contact Carol Hall WD8DQG, 4651 Cardinal Drive, Mt. Pleasant MI 48858; (517)-772-0363.

GUELPH ONT CAN
JUN 13

The Guelph Amateur Radio Club will hold the 6th annual Central Ontario Amateur Radio Fleamarket and Computer Fest on Saturday, June 13, 1981, at the Centennial Arena, College Avenue West, Guelph, Ontario, Canada. Admission is $1.00, with children 12 years and under admitted free. Admission for vendors is an additional $2.00. Tables are $5.00 each on a first-come basis. The hours are 8:00 am to 4:00 pm; vendors may begin setting up at 6:00 am. There will be commercial displays, computer software and hardware, surplus dealers, indoor and outdoor displays, and door prizes. The refreshment concession will open at 12:00 noon. Talk-in on .52/.52, .37/.97 (VE3KSR), and .96/.36 (VE3ZMG). For further information, contact Dennis Gore VE3DGA at (519)-836-6226 or Andy Janosik VE3GDY at (519)-824-3227.

WILMINGTON OH
JUN 14

The Clinton and Highland County Radio Clubs will sponsor their annual hamfest and flea market on June 14, 1981, rain or shine, at the Clinton County Fairgrounds, State Route 22, Wilmington OH, from 1200 to 2100 UTC. Admission is $3.00 and flea market space is free with admission ticket. There will be a sheltered display area, a food concession, an auction, and door prizes. Camping is available at nearby Cowan Lake State Park, as well as at private campgrounds and motels. King's Island Park is also nearby. Talk-in on 147.72/.12, 147.81/.21, or 146.52. For further information, contact Bob Lewis KE8E, 192 Northview Road, Blanchester OH 45107, or phone (513)-783-2740 evenings.

SANTA MARIA CA
JUN 14

The Satellite Amateur Radio Club will hold the Santa Maria Amateur Radio Swapfest at the Newlove picnic grounds (Union Oil Company), Santa Maria CA. For information on prizes, swap tables, dinner tickets, etc., mail inquiries to Santa Maria Swapfest, 1600 E. Clark #49, Santa Maria CA 93455.

OSCAR ORBITS

Courtesy of AMSAT

The OSCAR satellites are subject to atmospheric drag, of course, and the present period of intense solar activity has accentuated the problem. During this period, our sun has been expelling huge numbers of charged particles, some of which find their way into the Earth's upper atmosphere, increasing the density (and thus the drag) there. It is through this region that the OSCARs must pass. OSCAR 8, in a lower orbit than OSCAR 7, is the more seriously affected of the two.

If the drag factor is not considered when OSCAR calculations are performed, long-range orbital projections will be in error. For example, by the end of 1979, OSCAR 8 was more than 20 minutes ahead of some published schedules. The nature of orbital mechanics is such that extra drag on a satellite causes it to move into a lower orbit, resulting in a shorter orbital period. Thus, the satellite arrives above a given Earthbound location earlier than predicted.

Using data supplied to us by Dr. Thomas A. Clark W3IWI of AMSAT, the equatorial crossing tables shown here were generated with the aid of a TRS-80™ microcomputer. The tables take into account the effects of atmospheric drag and should be in error by a few seconds at most.

The listed data tells you the time and place that OSCAR 7 and OSCAR 8 cross the equator in an ascending orbit for the first time each day. To calculate successive OSCAR 7 orbits, make a list of the first orbit number and the next twelve orbits for that day. List the time of the first orbit. Each successive orbit is 115 minutes later (two hours less five minutes). The chart gives the longitude of the day's first ascending (northbound) equatorial crossing. Add 29° for each succeeding orbit. When OSCAR is ascending on the other side of the world from you, it will descend over you. To find the equatorial descending longitude, subtract 166° from the ascending longitude. To find the time OSCAR 7 passes the North Pole, add 29 minutes to the time it passes the equator. You should be able to hear OSCAR 7 when it is within 45 degrees of you. The easiest way to determine if OSCAR is above the horizon (and thus within range) at your location is to take a globe and draw a circle with a radius of 2450 miles (4000 kilometers) from your QTH. If OSCAR passes above that circle, you should be able to hear it. If it passes right overhead, you should hear it for about 24 minutes total. OSCAR 7 will pass an imaginary line drawn from San Francisco to Norfolk about 12 minutes after passing the equator. Add about a minute for each 200 miles that you live north of this line. If OSCAR passes 15° east or west of you, add another minute; at 30°, three minutes; at 45°, ten minutes. Mode A: 145.85-.95 MHz uplink, 29.4-29.5 MHz downlink, beacon at 29.502 MHz. Mode B: 432.125-.175 MHz uplink, 145.975-.925 MHz downlink, beacon at 145.972 MHz.

At press time, OSCAR 7 was scheduled to be in Mode A on odd numbered days of the year and in Mode B on even numbered days. Monday is QRP day on OSCAR 7, while Wednesdays are set aside for experiments and are not available for use.

OSCAR 8 calculations are similar to those for OSCAR 7, with some important exceptions. Instead of making 13 orbits each day, OSCAR 8 makes 14 orbits during each 24-hour period. The orbital period of OSCAR 8 is therefore somewhat shorter: 103 minutes.

To calculate successive OSCAR 8 orbits, make a list of the first orbit number (from the OSCAR 8 chart) and the next thirteen orbits for that day. List the time of the first orbit. Each successive orbit is then 103 minutes later. The chart gives the longitude of the day's first ascending equatorial crossing. Add 26° for each succeeding orbit. To find the time OSCAR 8 passes the North Pole, add 26 minutes to the time it crosses the equator. OSCAR 8 will cross the imaginary San Francisco-to-Norfolk line about 11 minutes after crossing the equator. Mode A: 145.85-.95 MHz uplink, 29.4-29.50 MHz downlink, beacon at 29.40 MHz. Mode J: 145.90-146.00 MHz uplink, 435.20-435.10 MHz downlink, beacon on 435.090 MHz.

OSCAR 8 is in Mode A on Mondays and Thursdays, Mode J on Saturdays and Sundays, and both modes simultaneously on Tuesdays and Fridays. As with OSCAR 7, Wednesdays are reserved for experiments.

HAM HELP

I've been reading over my old copies of *73 Magazine* this evening and thought I should write to *73* and thank everyone for the fine magazine I have had the opportunity to be reading these past months.

Now for the good news: As of Feb. 13, 1981, I was granted a parole. The man told me I got it not because I earned it, but because of my medical problem. To clarify that: I had an operation in November, 1980, for a pancreatoduodenectomy, a malignant tumor in the distal common bile duct. The good doctors gave me an expected chance of survival at less than 30% at five years.

But even with the bad news I'm trying to keep my head and still plan ahead. A good, very good friend will be helping me soon after I get home with the CW portion and will try to do all he can to help me get my Novice license; at least it will be something I've been trying to do in the 16 months I've been in this place.

Also, I've met many amateurs through the mails from a letter in Ham Help of May, 1980. These new friends have helped me more than I can express in mere words, and hopefully I can still keep in touch when I get home and later on the bands with my very slow CW. I was told by one good doctor to live my life the best I can and have fun. Only one knows when I'll leave this Earth, and that one is God alone.

I should be leaving the institution in 7-10 days; my papers say I'd be unemployable. But, somehow, I have to find a job or I will go stir crazy doing nothing. I will sure try to get even a part-time job some place, and may also do some work on gas engines (lawn mowers and cycles) to keep myself busy on the farm. If I do pass the test on the Novice, I'll surely get my feet wet, so to say, and jump in and listen on the bands and later try my fist with my lousy CW. Hopefully, I may even get good enough to go ahead and try for the Technician license later this year. Strange, though I can remember schematics, rules, regs, formulas, and electronic knowledge, I have trouble with CW. All I've got down so far is: E, A, T, SOS, and M and N. More and more practice is surely needed—maybe my brain is dense or something. I've read all I can on amateur radio, and have got a lot of books here to take home. Also, I've gone through the Novice *73* book 4-5 times since being here.

I reread the magazines as much as I can and think hopefully soon I'll get that license for sure.

I would like to thank everyone who wrote to me here and all the doctors and nurses at Iowa City, Iowa's University Hospital for everything while I was a patient there. I sincerely do appreciate it very much. I especially thank *73 Magazine* for putting my letter in Ham Help last May and Wayne Green, without whom *73* wouldn't be such a great magazine as it is today. Again, thank you all.

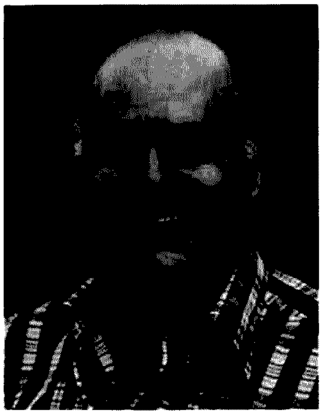
NEVER SAY DIE
editorial by Wayne Green



CQ'S BOO-BOO

The cover article on the April *CQ* was about the OH2BH trip to Sudan. Inside was a three-page article on the "expedition." Marty OH2BH, who has made such trips to many interesting places, pulled a serious boner with this one. The QSL card for the operation, which was *not* shown in the article, but was mentioned, had a picture of a starving child. To say that this was in bad taste is an understatement.

A card managed to get to the Sudan government people very quickly and the result was a serious black eye for amateur radio. It wasn't that anyone wanted to hide starvation; it was that, as far as I am able to determine, it doesn't exist in that country at present.

I talked with a ham recently back from the Sudan who had operated in both Khartoum and in Southern Sudan; he said that he had not seen anything like that anywhere he had been. The government officials were astounded and furious, because they know of no such starvation in the Sudan.

Amateur radio really doesn't need that sort of foreign relations.

HARTFORD CANCELLED

Things are really hurting, apparently. The ARRL New England Convention was cancelled recently. I gather that the reason was a lack of interest on the part of the usual exhibitors. Unfortunately, the show was cancelled far too late for the chaps who run the Boxboro (Mass.) convention to pick up the ball. So, at a time when the infusion of spirit that a convention brings is so desperately needed, there will be no New England convention at all!

Everything was going well with New England until their place for the hamfest (in Swampscott) burned down a few weeks before the show several years ago. They tried holding it in Boston, but that was not popular. Parking was expensive and cars are often stolen or vandalized if not parked off the streets in Boston.

They tried Cape Cod, but that was too far away and attendance was low. The site at Boxboro turned out to be a good one, but by the time that had been found, another group in Hartford had started putting on shows there and there was a good deal of push and shove. They settled down to alternating years. Unfortunately, Hartford did not have the right kind of area for a good hamfest. The hotel where they have been showing is too small, with little area for exhibitors...and an almost impossible situation as far as setting up exhibits is concerned. Parking is very expensive, etc.

The Civic Center at Hartford has more space, but it is far too large and too expensive, so there has been a lot of frustration all around. Perhaps the collapse of the Hartford convention will enable the Boxboro group to get into a regular yearly show. Our hobby needs this.

ARRL SURVEY

The recent ARRL survey, reported in *QST*, showed a readership of *73 Magazine* of 141,000. Since that about covers the *active* amateur population, that's not bad. This is certainly consistent, within the limits of their sampling method, with the results *73* surveys have shown, which indicated that about 150,000 licensed amateurs were reading *73*.

ORLANDO

Since I'm as popular as a mongoose in a cage of snakes at an ARRL convention, others of the *73* staff ran our booth at this event. The reports are that there was a good crowd, though they apparently brought very little money. Estimates run from 2,000 to 5,000, depending on the bias of the reporter.

Dannals was reported to have given his speech on how great the ham satellite communications would be if we had not lost 99% of our satellite channels ten years ago at Geneva. I'm sorry I missed that, for I really did enjoy it at St. Paul some years ago...and at other conventions. It left me really enervated.

Baldwin announced his approaching retirement, leaving members to wonder who will be his replacement. Speculation is that the top job will probably go Lee Aurick, known around HQ as "Mr. Nice Guy." Several directors hinted that Dannals, too, will be retired soon, with Mary Lewis being mentioned as the possible new president.

ANOTHER WINNER

Congratulations to Larry Groppi of Elk Grove IL, winner of a life subscription to *73 Magazine* at the March 14-15 Orlando Hamcation.

Another topic of discussion was some of the recent lawsuits brought against the League. Apparently more and more outraged members are aware that the League can be sued in their local area and not just in Connecticut. They can be sued wherever they do business. These suits are being won... look for details in *QST*. Go on and look.

There is some speculation as to whether the picture of directors Metzger and Bergman, both sound asleep during the board meeting, will be published in *QST*. Metzger got in when Don Miller was suddenly forced to resign the day before the ballot count. The hams in Indiana are really upset over what they consider the screwing of Miller... and do not seem to appreciate Metzger getting elected in spite of their vote against him.

Just in case I am unable to come up with anything positive about the ARRL in June, as promised, I do have a firmly positive thing to say about the League. I hope this will shut up those pinheads who are saying that I am anti-League. ARRL observers, who are privy to the inside skinny, assure me that there are now *two* good guys on the board of directors. Two out of 16 is fantastic and I think a round of huzzahs is in order. If this sort of thing keeps up, who knows what marvelous things we may eventually see.

In case the above does not completely satisfy the League brainwashed, I'll keep reading my mail, asking everyone in the industry, and in general making a pest of myself trying to come up with something really positive for June...or at least July. Keep your fingers crossed.

ARE THINGS GOOD?

No, not really. The recent *QST* editorials bemoaning their poverty have shaken a lot of complacent League members. The disappearance of a growing number of previously visible ham dealers has not gone completely unnoticed. The sudden demise of *Ham Horizons* was another clear indication. The panic dumping of ham gear at discount rates which are barely above wholesale prices by some ham dealers is another clear clue.

Those discount prices have been raising hell throughout the industry, by the way. The

manufacturers swear that they are not shipping much gear to these discounters, so there is no way in the world for them to fill orders once their past stock is out. Calls to some of them have shown clearly that they do *not* have the equipment to ship, so all they are doing, really, is keeping anyone from selling equipment. We hams, being dedicated skinflints, would rather die than spend an extra buck for a rig, even if we have to wait until hell freezes over to get it.

It appears that the importers of ham gear have responded to this situation by diverting much of their normal supply to take care of the increased need in Japan, where amateur radio is growing far more rapidly than it is here. Indeed, Japan has over twice as many active hams as we have right now and they are stepping up their push for new hams. Their leading ham magazine had over 40 pages of pictures of ham club activities last month...while I have yet to get one single such picture for *73*, despite editorials asking for them. I guess our clubs are pretty much dead ... particularly in comparison with the Japanese.

73 has had to thin down to cope with the drop in equipment sales. To keep a magazine viable, you have to run about 40% advertising. *Ham Horizons* got down into the 20s...the kiss of death. *CQ* ran in the 30s last year, causing much concern in the field. *HR* was also in the 30s...low 30s...another disaster was possible. Publishers watch things like that with an eagle eye.

Rather than sit back passively, I have some ideas which could revitalize amateur radio. Those of you who were around ten years ago can testify as to the results of my push for FM and repeaters...with no help whatever from any of the other magazines...and vigorous opposition from the ARRL. Despite that, FM went from the private province of perhaps 2,000 hams to the single most active aspect of the hobby. It can be done again.

Though my initial approaches to Radio Shack were rebuffed, I have by no means given up with them. Never Say Die, remember? I am going to keep after them until they at least give my idea a test and prove it won't work. I'm going to see what I can do with Heath and their 50+ stores...all of the ham dealers in the country...and so on. Once we have our new *73* training series ready, I'll be pushing every club I can find as hard as I can to get hopping to get amateur radio back into a strong growth mode. In case you don't know it, we lost over 50% of the people we tried to get into amateur radio through inferior teaching materials.

Repeater at 102,000 Feet!

—Canadian hams go up, up, and away

Seventy miles north of Winnipeg, on the western shore of Lake Winnipeg in Central Canada, lies the small fishing village of Gimli. The town's main claim to fame is in being the oldest existing Icelandic community in Canada.

Gimli Air Force Station, now an industrial park, was for years a pilot training school, and for a short time was home for many World War II pilots and, later, for pilot trainees from NATO countries.

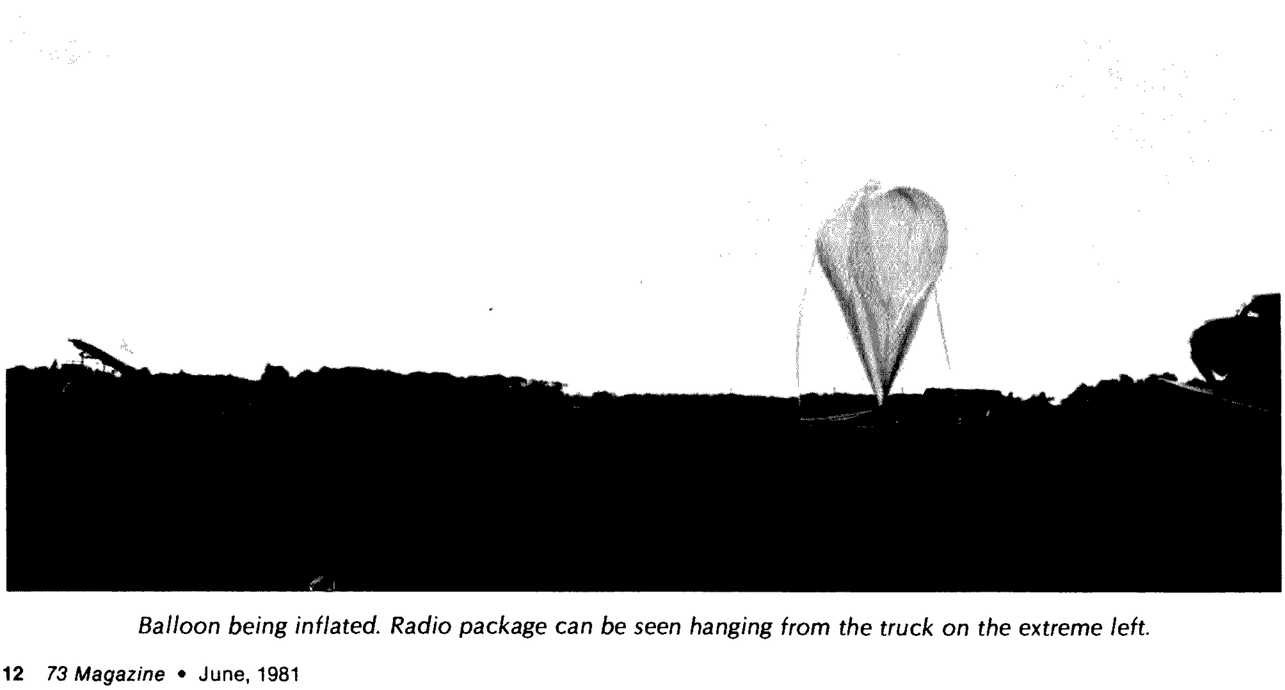
During the spring of 1979, the Space Research Facilities Branch of the National Research Council (the Canadian equivalent of NASA) reopened the deactivated airport as a launching base for high altitude scientific balloons, its two long runways making it an ideal site.

The initial launches were partly to train launch crews and partly to investigate any effects on launch procedures due to the proximity of a large body of water. Later, high-altitude balloons launched from this site would carry various scientific experiments into the lower stratosphere, these balloons being designed to cruise at 100,000 to 150,000 feet, or 20 to 30 miles.

At this time, Larry Toms VE4VX and his brother Max worked as instrumentation technologists with the contractor operating the launch facility for NRC. The possibility of an amateur radio experiment hitching a ride on one of the training flights occurred to Larry and Max, and enquiries were made through NRC official channels. Hopes were not high as no firm plans of what the experiment configuration might be had been formulated, and therefore no formal proposal could be made. Only a request was made that a 2-meter repeater, the design of which would evolve as construction proceeded, was to be flown.

On June 21st the cruncher came! Yes, permission was granted to fly an amateur radio experiment on balloon flight number 7907B scheduled for launch on or after July 18th! Only 26 days to go and only a vague concept of what the experiment would be—no hardware, no money, no work force. . .!

Much thought and head-



Balloon being inflated. Radio package can be seen hanging from the truck on the extreme left.

Flight Payload Specifications

Weight:	250 lb.
Repeater	Transmitter Power: 1 Watt
	Frequency: 147.33 MHz
	Modulation: FM, 3.5-kHz deviation
	Antenna: Modified ground plane
	Mode: Simplex/duplex, commandable
Link:	Transmitter Power: 1 Watt
	Frequency: 144.33 MHz
	Modulation: FM, 3.5-kHz deviation
	Antenna: Modified ground plane
Beacon:	Transmitter Power: 80 milliwatts
	Frequency: 432 MHz
	Mode: CW
	Antenna: Turnstile
Power Supplies:	+ 16 V dc, 35 Ampere/hour
	+ 15 V dc, 1 Ampere/hour
Total Current Drain:	1 Ampere/hour
Command Signals:	+ 24-volt pulse, 80-ms duration
